The
BUILDERS' JOURNAL
AND
ARCHITECTURAL ENGINEER

APPEALING TO THOSE ENGAGED IN

THE ART OF BUILDING

It is our aim, our ambition, our aspiration even, to build our Journal worthily and well, not for the hour only, but for future years; for the few men in the forefront of an enduring and a laborious art; for the disciplined ranks of a distinguished profession; for the young men—Architects to be—and for all who love a clustered column or a flying buttress, a traceried window or a Greek frieze; for the man, too, who honestly plumbs a jamb. . . . .

CAXTON HOUSE, WESTMINSTER.

YEAR, A REVIEW OF THE, 515—517.
Year Book, Liverpool Master Builders', 307.
York Minster, Fire at, 179, 246.

CONTENTS, CONCRETE AND STEEL SECTION.

ABSORBENT AGGREGATE, CONTRACTION CRACKS DUE TO AN, 364.
Adhesion of Steel to Concrete, 288.
Arched Ribs, Concrete, 441.
Arched Roof Principals, 207.
Arches, Reinforced Concrete, The Design of, 441.
Architect's Chance, The, 208.
Architectural Treatment of Reinforced Concrete, 207.
Assumptions, Unproved, 47.

BEAMS, CONTINUOUS, 364.
Bending Moments, 363.
Bridge, A Transportable, 58.
Builders' Notes, 53.
By-laws, Rules and, 364.

CANTILEVERS, 207.
Causes of Faulty Concrete Construction, Some, 370, 384.
Cement Grout, 285.
Cement Users, Some Common Complaints of, 52.
Centering for Reinforced Concrete, 208.
Centering, Metal, 208.
Coal, Contractors' Use of, a Scientific System of Buying, 32, 57.
Colonies, Reinforced Concrete in the, 47.
Columns, Connections with, 364; Strength of, 48.
Commercial Aspect, The, 208.
Complaints of Cement Users, Some Common, 52.
Concrete Arched Ribs, 441.
Concrete Industrial Village, A, 287.
Concrete Notes, 131.
Concrete Steel, 131.
Concreting, Practical, 56, 74, 137.
Conduit, A Reinforced Concrete, 53.
Connections with Columns, 364.
Continuous Beams, 364.
Contraction Cracks due to an Absorbent Aggregate, 364.
Contractors' Use of Coal: A Scientific, System of Buying, 32, 57.

DESIGNS, FRENCH REINFORCED CONCRETE, 208.

EDISON POURED HOUSE, THE, 55.

Electrolysis in Reinforced Concrete, 285.
Equilibrium Polygon, The, 441.

FACTOR OF SAFETY, THE, 364.
Factory at Harrow, Reinforced Concrete, 139, 443.
Faulty Concrete Construction, Some Causes of, 370, 384.
Ferro-Concrete, Reconstruction in, 48.
Fixed or Continuous Arched Rib, 442.
Flexure, 207.
Floor Slabs, 207.
Formulæ Fail, Where Elaborate, 47.
Formulæ, Short, 47.
French Reinforced Concrete Designs, 208.

GENERAL POST OFFICE BUILDINGS, THE NEW, 448.
Grout, Cement, 285.

INSTITUTION OF MECHANICAL ENGINEERS, 132.

JUNIOR INSTITUTION OF ENGINEERS, THE, 448.

LEADERETTES: Short Formulæ; Where Elaborate Formulæ Fail; Unproved Assumptions; Reinforced Concrete in the Colonies, 47; Strength of Columns, 48; Steel Concrete; Moulded Lumber, 131; Flexure; Floor Slabs; Arched Roof Principals; The Outward Form; Architectural Treatment of Reinforced Concrete; Cantilevers, 207; The Architect's Chance; French Reinforced Concrete Designs; Centering for Reinforced Concrete; The Commercial Aspect; Metal Centering, 208; Cement Grout; External and Internal Pressure; Electrolysis in Reinforced Concrete, 285; Testing Completed Reinforced Concrete Buildings; Bending Moments, 363; Continuous Beams; Rules and By-laws; Connections with Columns; The Factor of Safety, 364; The Design of Arches; Stresses in Natural Stone; Concrete Arched Ribs; Reinforced Concrete Arches; The Neutral Axis; The Pressure Curve; The Equilibrium Polygon, 441; Winkler's Criterion; The Three Methods;; Fixed or Continuous Arched Rib, 442.
Lintels, Reinforced Concrete, 53.
Lumber, Moulded, 131.

METAL CENTERING, 208.
Mining Work, Reinforced Concrete in, 214.
Moulded Lumber, 131.

NEUTRAL AXIS, THE, 441.

PALACE, TYNEMOUTH, 51.
Papers Read: "Reinforced Concrete," by Arthur C. Auden, 132, 163; "The New General Post Office Buildings," by Thomas A. Watson, Assoc.M.Inst.C.E., 448.
Piles, Reinforced Concrete, 133, 209, 286.
Points About Shear Stresses, 442.
Poured House, The Edison, 55.
Practical Concreteing, 56, 74, 137.
Pressure Curve, The, 441.
Pressure, External and Internal, 285.

RECONSTRUCTION IN FERRO-CONCRETE, 48.
Reinforced Concrete, A Factory in, 443; Arches, 441; Architectural Treatment of, 207; Buildings, Testing Completed, 363; Centering for, 208; Conduit, A, 53; Electrolysis in, 285; Factory at Harrow, 139; in Mining Work, 214; in the Colonies, 47; Lintels, 53; Piles, 133, 209, 286; Smoke and, 289; System, The Leslie, 364; Theatre, A, 294.
Researches, Theoretical and Experimental, 289, 368.
Roof Principles, Arched, 207.
Rules and By-laws, 364.

SAFETY, THE FACTOR OF, 364.
Shear Stresses, Points About, 442.
Short Formulæ, 47.
Slabs, Floor, 207.
Smoke and Reinforced Concrete, 289.
Steel Concrete, 131.
Steel to Concrete, The Adhesion of, 288.
Strength of Columns, 48.
Stresses in Natural Stone, 441.

TESTING COMPLETED REIN FORCED CONCRETE BUILDINGS, 363.
Theatre, A Reinforced Concrete, 294.
Theoretical and Experimental Researches, 289, 368.
Three-Hinged Concrete Trusses, 213.
Transportable Bridge, A., 58.
Trusses, Three-hinged Concrete, 213.
Tynemouth Palace, 51.

UNPROVED ASSUMPTIONS, 47.

VIEWS AND REVIEWS: "Applied Mechanics for Engineers," 49; "The Instantes Decimal Tables of Weights, Measures, Theories, etc.;" "Statics by Algebraic and Graphic Methods;" "Introduction for the Chemistry and Physics of Building Materials," 50; "Portland Cement;" "Reinforced Concrete in Europe," 291; "Applied Mechanics for Engineers;" "The Elements of Mechanics of Materials," 441; "The Calculus." 443.
Village, A Concrete Industrial, 285.

WINKLER'S CRITERION, 442.

ILLUSTRATIONS.

"A. Beckett's," West Lavington, Wilts, C.P., Sept. 22nd.
Aberdeen, The Prudential Buildings, 438.
Additions to Brandon, Sheffield, C.P., Aug. 18th.
Almshouses at Hertford, Old, 406, 407.
America Square, London, Doorway at No. 16, 124.
American Architecture, Modern (see Modern).
Angley Park, Cranbrook, Kent, House at, 105—108.
Annfield Plain Public Library, 403, 405, and C.P., Nov. 24th.
Arched Floor Construction at Messina, 455, 456.
ARCHITECTS OF THE DAY: II.—MR. ERNEST NEWTON, F.R.I.B.A., Portrait of Mr. Newton, 22; Luckley, Wokingham, Berkshire, the Entrance and Forecourt, 23; Plans; The Hall, 24; Redcourt, Haslemere, 25; Dining Room Chimney Piece, 26; Fouracre, Winchfield, Hants, Garden Front, 31; Upton Grey, Hants, Entrance, 32; Bay on Garden Front, 33; General View of Entrance Front, 34; Martin's Bank, Bromley, Kent, 35; Plan, 35; St. Swithin's Church, Hither Green, London, S.E., Interior, looking east, 36; Ardenrun Place, Blindley Heath, Surrey, C.P., July 14th, Plans, 28; Mr. Ernest Newton, F.R.I.B.A., sketched from life by our Special Artist, additional plate, July 14th. III.—MR. MERVYN EDMUND MACARTNEY, B.A., F.R.I.B.A., F.S.A., The Smoking Room, Angley Park, Cranbrook, Kent, 105, 108; Principal Lodge, Angley Park, 106; Staircase, Angley Pork, 107; Lodge at Angley Park, 108; The Hill Meadow, Baughurst, Hants, 109; Pump House, Seddlescombe, Sussex, 109; House at Woolhampton, Berks, 110, 111; Mr. Macartney's Second Home at Silchester Common, 110; Plans of House at Woolhampton, and House at Newbury, 112; Welders, Chalfont, Bucks, 113; Frithwood House, Northwood, 114, 115; Mr. Macartney's new Home, Woolhampton, Berks, 115, 116; Bussock Wood, Newbury, Berks, C.P., Aug. 11th; Mr. Mervyn Edmund Macartney, B.A., F.R.I.B.A., F.S.A., sketched from Life by our Special Artist, additional plate, Aug. 11th. IV.—MR. GEO. B. POST, of New York: Portrait of Mr. Post, 181; Main Building, College of the City of New York; Bird's Eye View of the College, 182; Main Hall of the College, 184; Suggested Improvements, Newport Harbour, Rhode Island, 185; Wisconsin State Capitol, 186, 187; The Howard Savings Institution, Newark, New Jersey, 187; New York Stock Exchange, 188; Entrance, College of City of New York, 190; George Washington Memorial Buildings, Washington, D.C., 191. V.—MR. DANIEL HUDSON BURNHAM, of Chicago: Portrait of Mr. Burnham, 259; The Illinois Trust Company's Building, Chicago, 260; The "Flat-Iron" Building, New York, 261; Union Station, Pittsburg, Pa., 262; First National Bank, Chicago, 263; First National Bank, Pittsburg, 264; The People's Gas Company Building, Chicago, 265; Gimbel Brothers' Building, New York, 266; The Original Design for the Selfridge Store, London, 267; The Athenæum, San Francisco, 268; Telegraph Hill, San Francisco, 269; The Commercial Bank Building, Chicago, 270. VI. and VII.—MESSRS. LANCHESTER AND RICKARDS, FF.R.I.B.A.: Bird's Eye View of the Wesleyan Methodist Hall, Westminster, 337; "Tortos," A Character in the A.A., Play of 1909, from a pencil sketch by E. A. Rickards, 338; City Hall and Law Courts, Cathays Park, Cardiff, 339; Interior View of the Law Courts, 341; Entrance Doorway, Bovril Warehouse and Offices, 343; Plan of Design submitted in the Geneva Memorial Competition, 345; City Hall, Cardiff: The Assembly Hall, 346; Hull School of Art, 347; Deptford Town Hall, [illegible]: The Council Chamber, 351; Centre Plate: Messrs. Lanchester and Rickards, sketched from Life by our Special Artist. Fire Prevention at St. Paul's Cathedral.

The accounts that have appeared in the daily Press with respect to the new scheme of fire-protection for St. Paul's Cathedral are, we are informed, unauthentic. It is true that a scheme is under consideration, but the details have not yet been made public. The generalisation, however, cannot be very far wrong. The cathedral is surrounded by tall buildings, many of which are filled with highly inflammable goods. Fires in the district have been fairly frequent, and in some instances have seriously menaced the safety of St. Paul's. The danger is greatly increased by the vast height of the dome, which, while it might easily take fire by having burning materials blown against it, is inaccessible to the fire brigade, who could not raise water so high. Their appliances are not effective beyond a height of seventy or eighty feet, whereas the dome of the cathedral is about 300ft. high. The cathedral, of course, has its own storage tanks, but if these were exhausted ineffectually, London's grandest landmark would melt before the gaze of the awestruck and helpless crowd. In order to prevent such an unspeakable catastrophe, the surveyor of the cathedral is no doubt endeavouring to avail himself of all the resources at command, and, by making use of the high-pressure system he will be able to render the cathedral virtually immune from the ravages of fire; always provided that his well-devised scheme is not crippled for want of funds. In the richest city in the world, and where the existence of that city's noblest building—its veritable *genius loci*—is concerned, the sum required should be obtained without the slightest difficulty.

The Disaster at Newport.

In spite of all that can be done by the exercise of the utmost available knowledge, skill, and foresight, it is seldom indeed that a great constructional work can be carried to completion without the occurrence of some serious accident involving the risk or forfeiture of human life. Indeed, on an engineering work of any considerable magnitude, such accidents are regarded as being incidental and almost inevitable, and complete or comparative immunity from them is nearly always the subject of surprise and congratulation. So puny is man in comparison with the titanic forces he can set in motion, that it would be wonderful if he could ever get them under complete control. The appalling disaster that occurred at Newport, Monmouth, last Friday, is exceptional only in the number of its victims, of whom more than thirty were killed, while some of the survivors will be maimed for life. The accident was of a kind with which builders and contractors are only too familiar. A trench, about 30ft. wide and 60ft. deep, suddenly caved in—from what cause, stringent enquiry may or may not ultimately reveal. Although, as the result of very frequent accidents, very special attention has been given to the timbering of trenches, and collapse is consequently now far less frequent than it used to be, there is always the haunting fear that some unknown characteristic of the soil, some undetected weakness of the walling or strutting materials, or some thoughtless action on the part of the users, may nullify the most elaborate precautions and produce most lamentable disaster. That the toll of human life exacted by constructional works is far less than that imposed by railway and motor accidents, and in coal-getting, is but a melancholy consolation, and will not relax in the slightest degree the humane, strenuous, and persistent effort to reduce risks to a minimum.

Art and Dogma.

The Bath Street controversy has given rise to discussion of an interesting side issue. According to Mr. Eustace Balfour, F.S.A., F.R.I.B.A., the chairman of the Baths Committee of Bath has written "an amazing sentence" involving "a dogmatic statement of the proportions which should govern Ionic columns." Mr. Balfour points out that "there is no rule of architectural proportion except that of taste and judgment. The proportions of a column are dependent quite as much upon its material and the weight which it has to carry, as upon any authority of Classical or Renaissance times." He thereupon suggests taht Vitruvius should be read in the light of Palladio, which, in any circumstances, is excellent advice. But in the chairman's sentence there is surely nothing that deserves the strong adjective "amazing," unless we are to take that much-abused word in its modern or newspaper-placard sense, and to consider that, by habitual misuse, it has lost its original force and thrill. Possibly the chairman is still under bondage to the precisians who thought that the study of the Orders was an exact science, and who refused to be shaken in that belief by the ascertainments of Messrs. Stuart and Revett and the late Mr. Penrose. The rigid adherents to diameter theories have been perhaps subject to some confusion of thought. Seeing that, for instance, the Ionic differed from the Doric in being more slender in relation to its height, they may have thought it convenient to find in each case a fixed standard of proportion, or absolute ratio; unmindful that, though there may be a good deal of truth in the allegation that "science is measurement," more liberty is demanded by art. The builders of the Early Christian churches seem to have gone to the opposite extreme. In appropriating columns from the ruins of basilicæ, they seemed to care not a jot for proportion. If a column was too tall, they simply cut it down; if it was too short, they mounted it on a pedestal. Their example is only less exasperating than that of the dogmatic rule-of-proportion school because, unlike the latter, they were usually governed by necessity.

Land Values and Buried Treasure.

Italy also has, or has had, its land-value problem; and, as with us, there has been hot controversy on the question of ungotten treasures. The archæologists desired a law declaring that a landowner possessed no archæological property beneath the soil, or, in other words, no right whatever to antiquities found in excavation, and that he could only claim compensation for loss or damage done to his land by the process of excavation. The law, however, as recently amended, deals more tenderly with the landowner, giving him a fourth part of the value of the antiquities discovered. On another point the archæologists have scored heavily. It has been decided that in assessing the value of the land expropriated by the State for excavation no account is to be taken of the presumed value of antiquities that may be found beneath. This alteration is probably a direct consequence of the impossibilist attitude of certain holders. Hitherto, for instance, it has been impossible to expropriate the unexplored portions of the site of Herculaneum owing to the fabulous price demanded by the owners. In this and in other instances, private interests, though duly regarded, will no longer be allowed to obstruct research that may put the world in possession of discoveries of vast importance to art, architecture, and archæology. The value of this concession may be illustrated from a recent instance. An hotel keeper who had received permission to make excavations on private property at Pompeii has laid bare the remains of a large villa, containing a dining-room, in which there are frescoes of exquisite workmanship, representing Silenus giving drink to a thirsty man—a subject that must have hugely delighted the archæologically inclined Boniface—an Ariadne, and a winged Victory about to strike a vanquished woman, for whom a third woman is interceding. Here the Government has intervened, stopping the excavations, and prohibiting the removal of the frescoes. The new law forbids all irresponsible traffic in art treasures. In England we have, of course, the law of treasure trove; would also that we had an art-sensitive State!

Londonderry's Level Lump Sum. The corporation of the historical city of Londonderry seems to hold peculiar views on the subject of contracts, and it clings to them with all the tenacity that one might expect from the descendants of the heroes of the famous siege. The Guildhall is to be rebuilt, and the corporation doggedly insist on having "a lump-sum contract" for the job. So far as we can gather from a full report of a protracted debate on the subject, the worthy burgesses of Derry think that their interests will best be served if they can get a contractor to state that he will do the work for a rigidly fixed sum, with all extras barred. In vain the Architect, the Town Clerk, and the City Surveyor indicated that more latitude was desirable. The corporation seemed to be infatuated with the lump-sum theory. Even after the very careful explanations of their expert advisers, these City Fathers remained obdurate. In vain they were warned that the application of Medo-Persic rules to building operations might lead to expensive litigation, and that, in any case, to pin down the contractor to a lump sum was to handicap him to their own detriment. The architect, easily more wise than his dogmatic employers, had set down a provisional sum for ventilation. This they resented. In their view a specification must be definite and final in every item, and complete down to the most minute particular. Otherwise how could one arrive at an inviolable lump sum? To comment on such an absurd attitude would be mere waste of words. Londonderry corporation should buy their Guildhall ready-made. It is positively the only way in which to secure a bargain on the lump sum theory.

The Patriarchitect. The subjects that were under discussion at the Congress of French Architects at Toulouse are, from our insular point of view, chiefly interesting for their incidental revelation of certain points that are refreshingly novel. It became obvious, for instance, from the paper and discussion on assurance against professional risks, that the French architect is more subject to pains and penalties than is his professional brother in this country, and that, unless M. Gouault has miscalculated or has been misreported, the total amount of the premiums paid by French architects for assurance against such exactions is 500,000 francs, which is estimated as representing two per cent. of the architect's fees. Apparently the architect of a French building is held accountable for everything that goes wrong; and, as if this burden of plenary responsibility were insufficient, the architect must needs take upon himself the solution of the apprenticeship difficulty—a matter that our own architectural societies would regard as being the purely domestic concern of the builders. The French architect, however, seems to be regarded as the patriarch or patriarchitect of each tribe or clan of builders — the real *architecton* or chief builder—to whom all the rest may confidently look for both professional and paternal guidance. So was it in these islands in the days of old; but we seem to be getting further and further away from the old traditions. The fissures are not only widening, but increasing in numbers; the newest "split" being that of the architectural assistants.

Bulls. He that is not grateful for a bull is as fit for strategies and treasons as the man that hath not music in his soul. We hasten, therefore, to share our innocent joy in rather a neat one that appeared in a newspaper description of the Birmingham University Buildings. The writer descants upon the height and beauty of the clock tower, which is to commemorate the name of the Right Hon. Joseph Chamberlain, who has played so strenuous and so effectual a part in the founding of the University. The tower, the writer says proudly, is conspicuous for miles around. He adds, immediately, that the University buildings completely realise Mr. Chamberlain's ideal as "something that is not to be seen anywhere else." Cart-horses should not drag from us the source of this delectable bull. A somewhat similar infelicity of juxtaposition hardly attains to the dimensions of a full-grown bull, although it comes from Cork. "The fifties introduced [to Cork] the romantic school, its chief exponent being William Atkins, who designed the Lunatic Asylum. . . ."

House Pride. Once we were considered to be a purse-proud people. Now, according to the "Spectator," we are becoming house-proud, which is far better. "House-pride burns to-day as it has never burnt before. We have all become exquisitely conscious of our environment." That is good only as far as it goes; for it appears that "a new self-consciousness is destroying the picturesqueness of a thousand villages, and is studding the railway line all over the Home Counties with hideous tiny villas." Why are those tiny houses hideous? Because, apparently, the awakening sensitiveness to art has taken the builders by surprise. They have not yet realised that half-a-century of education has given birth to a strong feeling for beauty; and that feeling itself, though strong, is no more than rudimentary. It needs training and refining. Here surely a splendid opportunity for mission work presents itself. Formerly the people were stonily indifferent to the architectural amenities of their dwellings. The stolid householder was a veritable Gallio, caring for none of these things. Now, it would seem, he is in a most responsive mood, and would gladly render his house beautiful within and without if only he knew how. The better-class surburban dweller has already got hold of the gospel. He lives in a house that is by no means hideous in its construction or in its plenishings. It is not impossible that his example will yet percolate to the lower strata. Then we shall get architecture in the humblest dwellings.

MODERN ECCLESIASTICAL ARCHITECTURE.

By G. Gilbert Scott.

At the fourth ordinary meeting of the Architectural Society of the University of Liverpool, held on Thursday, June 10th, Mr. G. Gilbert Scott read a paper on "The Problem of Style in Modern Ecclesiastical Architecture."

In order to understand the present state of chaos, Mr. Scott said, it must be borne in mind that the widely divergent and often conflicting views held by those architects who honestly have the improvement and advancement of modern architecture at heart may be broadly divided into two main schools of thought—that held by a majority which is striving to pick up the broken threads of a lost tradition, and is attempting to evolve a new phase of the Renaissance, and that held by a minority, working in an entirely different direction. Mr. Scott said that, as a member of that minority, he felt it incumbent upon himself to explain and justify his position. In such a justification it was obviously necessary to put aside those individual preferences which have arisen merely from natural inclination or initial training, and to consider the whole question of the relative possibilities of modern Gothic and Renaissance architecture for ecclesiastical work, on the merits of actual evidence alone. In considering the two most prominent styles of our time, whatever may be urged against the legitimacy of Gothic, on the grounds of its being exotic, can with equal force be applied to any other style that has no claim to the title of Renaissance, the naturally predominant modern manner.

An examination of the whole case, Mr. Scott contended, inevitably leads to the discovery of the inadequacy of Gothic for the secular requirements of present-day civilisation; but in one branch of architecture, church-building, the case is entirely reversed. The validity of this contention Mr. Scott based on the hypothesis that achitecture, to be good, must be logical, and to be logical must reflect the conditions and feelings of contemporary life. To obtain a true answer to the question, "Is the Gothic style exotic?" it is necessary first to observe the distinctive characteristics of the Gothic style so that it may be possible to ascertain what special qualities it is best able to express, and then to make some excursion into the realms of sociology in order to examine the forces of modern life of which architecture should be the unconscious reflection.

The generally accepted superiority of Gothic is its power to express true religious feeling, and the current belief that it undoubtedly possesses characteristics appertaining to the Christian religion, which may not be claimed by the other style, cannot wholly be ascribed to association—to the fact that we have so long been accustomed to seeing churches in Gothic that unconsciously we associate the style with religion, and imagine it to possess an atmosphere of sanctity that is in no sense an innate quality of the style itself.

Rather it is precisely this quality which distinguishes it from Renaissance ecclesiastical work. In the latter the suppression of all spontaneity, the calm self-conscious intellectuality always evident, are more in keeping with the self-satisfied worshipper of science than with the humble and self-effacing spirit of the Christian. A fine Renaissance church appears a product of the intellect, a fine Gothic church a product of emotion. And in this lies the superiority of the Gothic style in religious appropriateness. The interior of a Renaissance cathedral seems more suitable as a setting for the tombs of national heroes than for the purposes of Christian worship, and, for this reason the Wellington monument in St. Paul's—which Mr. Scott considered the finest tomb in the country—is the right thing in the right place, and thoroughly in keeping with the very worldly spirit of the whole

—the tattered and war-stained flags, the coats of arms, and the general irreligiously impressive atmosphere of imperial magnificence.

But the question now arises, is the capability of the Gothic style for devotional feeling one which the requirements of modern civilisation actually demand for their full expression? Considered in relation to other phases of social life, is religion in its present position and character a living force, one to be taken into account and sufficiently strong to possess an influence upon contemporary architecture? To a limited extent it would appear undoubtedly to be so. The tolerant indifference of the majority is opposed by the earnestness of a minority to whom religion is a reality, and who are consequently anxious for it to be enshrined in a befitting and appropriate manner in structures that reveal their true purpose.

And as modern architecture, to be of genuine value, must express modern conditions and requirements, so it follows that the definite existence of this minority may be taken as a complete justification for the employment of Gothic in church design.

But the character of such work must, to be worthy of consideration, be free from all that affectation which, since the pre-Raphaelite movement, has in many quarters become synonymous with Art, and must be thoroughly modern in spirit. Mediæval work, beautiful as it is, is an impossibility in these days of individuality in Art. It was more the product of Guilds than of single master-minds, and in consequence its chief characteristic is the extraordinarily free and irresponsibly random manner of design, resulting in an unconscious picturesqueness, which is often increased by the inconsequence with which later additions were made; so that almost all mediæval buildings appear to have been put together partly by accident, and with so little regard to the relation of the various parts that no strong controlling quality of design, in the strictest sense of the word, is anywhere evident—there is no evidence of a supreme personality.

Chartres Cathedral, however, really possesses this quality, and for that reason Mr. Scott considered it to be the finest in Europe, and the only Gothic cathedral which ever inspired him with any enthusiasm; and to those people who sometimes expressed the supposition that he had studied a great number of old cathedrals and derived much inspiration from them, he said he was obliged to confess that he had never seen a cathedral that really fired his enthusiasm until he saw Chartres four years after the production of his design for Liverpool Cathedral. In this notable exception of Chartres, a strong personality dominates the whole composition: the subsidiary parts, such as windows and buttresses, are all designed to help the expression of the one great abstract idea. The scale is heroic, so that the work is one of those instances of the grand manner so very rare in Gothic. Though the majority of mediæval cathedrals are large in themselves, they are yet made up almost invariably of details on quite an unimposing scale, and the feeling of immensity that ought to be produced is frittered away in the smallness and trivial subdivision of the parts. Beauvais may be taken as a typical example of this, and it is instructive to compare its effect with that of Chartres. To obtain largeness of scale, a most careful and reticent treatment of the component parts of the whole is essential: they must not be obscured in a multitude of petty decorative features and frivolous little pinnacles and crockets, but all unnecessary detail must be eliminated, till only such is left as is essential to the design and contributes to the impact which the whole makes upon the mind.

But the true Gothic feeling is not to be found in our heartlessly restored cathedrals that are now nearly all dry bones and cast-iron, soulless museum relics. It is to be found rather in our little out-of-the-way, unknown and unrestored village churches. From these the spirit and not the mere forms of the style are to be learnt, and once that has been captured by the architect, it is possible for him to design with such freedom that imitation of mediæval work becomes more of a labour than the working out of new ideas. But in these days the style has comparatively few architectural exponents, and its very existence is due in large measure to the natural preference shown for it by the clergy and archæological laymen.

In studying the Gothic Revival, it is interesting to observe how in the first period of the movement knowledge of mediæval forms was considered the essential for a true interpretation of the style; and as the movement progressed the spirit of the style began to be discovered, and pedantic accuracy of form to be ousted from its supreme position, so that in the second period, the period of Bodley, Garner, George Gilbert Scott, and others, the work was distinguished by a happy balance of scholarship and artistic feeling; while in the third and present period, archæological knowledge occupies a position of comparatively slight importance, the artists preferring to rely solely upon their own feelings—usually with disastrous results. In their anxiety to avoid archæology, they rush to the other extreme and produce very shallow work.

The originators of the revival were men inspired with almost fanatical enthusiasm, and enjoying the most enviable opportunities. Yet the work of the period is undeniably dull and unconvincing. The true inwardness of the style was not grasped: the outward forms were seized upon as essentials, and archæology so strongly developed that it began to be mistaken for the art of design—an error which still persists amongst laymen who have taken up the study of

BIRMINGHAM UNIVERSITY: GREAT HALL. SIR ASTON WEBB, C.B., R.A., F.R.I.B.A., AND E. INGRESS BELL, ARCHITECTS.

The Great Hall, in which the King performs the opening ceremony to-day, runs north and south, and at the south end there are a stained glass window, the gift of Sir John Holder, and a fine organ, which has been presented by the family of the late Mr. Charles Harding.

mediæval work as a hobby. Lack of any depth of insight leads them to attach importance to externals, and having the history of the style at their finger-tips, they fancy that they know all that there is to be known about it, and proceed with extraordinary confidence to sit in judgment on any modern design that may come to their notice.

The extreme difficulty of producing really good modern ecclesiastical Gothic lies largely in the appalling freedom of the style—a freedom which quickly betrays the incompetent artist: there are no orders for him to fall back upon, no recognised proportions to use as a foundation upon which to base his design. He must rely solely and entirely upon his own sense of fitness. The repetition to a motif a few times constitutes a crime. A man may use an Ionic order all his life and not be accused of repeating himself. Yet let him occasionally repeat a particular Gothic column and arch, and he stands condemned for poverty of invention and lack of resource. Moreover, it is allowable to follow a type more closely in Renaissance work than is permitted in Gothic, with the result that architects erecting buildings, say in the Queen Anne manner, may copy a type very closely indeed, and still escape the accusation of plagiarism. Mr. Scott declared that, in short, after designing both in the Gothic and Renaissance manner, he had come to the conclusion that it is more difficult to do good work in the former than in the latter.

Mr. Scott concluded his lecture by discussing the possibility of evolving a certain type of Renaissance church that would possess the essential religious atmosphere—a dream which he thought would probably prove too Utopian for actual realisation. Brunelleschi's interior of the Badia at Fiesole is imbued with poetic charm, the plain plaster walls and the simple details accentuating rather than concealing the construction, contributing to produce a wonderfully appropriate and impressive feeling of religion. The work contains a seed that never grew or blossomed in subsequent development, and Mr. Scott expressed the hope of having at some time the opportunity of trying its possibilities.

The lecture was followed by a discussion on Scale, in which Professor Reilly and Professor Adshead took part.

A NEW FIRE EXTINGUISHER.

All who are interested in the question of fire extinction are familiar with the dangers and difficulty inherent to combating conflagrations where petroleum, gasoline, benzine, or other liquids lighter than water, are involved. As is well known, the attempt to extinguish with streams of water in such cases results usually in a spreading of the inflammable liquid, an increase of the area of combustion, and a greater intensity of conflagration. The use of steam or of a current of inert gas is available only for incipient conflagrations in well-closed rooms. It presupposes, also, the permanent location, on the spot, of stationary apparatus for the purpose. According to the American Consul at Chemnitz, a distinct step forward in the means of battling with such conditions has been made in Germany, where the use of a tenacious foam, dissipated with difficulty, has been found of great value in cutting off the supply of air necessary to maintain combustion, and thus extinguishing flame. The method and the requisite apparatus have been perfected at Salzkotten, near Minden, in Prussia, and have been submitted to exhaustive tests by the heads of the fire brigade and others interested in the question of protection against the dangers from combustible liquids.

The apparatus employed consists of a simple metal cylinder provided with a long spout, and divided into two chambers. One chamber is charged with an aqueous solution of potash alum and sodium sulphate, the other with a similar solution of sodium bicarbonate, sodium sulphate, and liquorice extract. The cylinder is so arranged that, on being inclined or reversed, the two solutions mingle as they issue from the spout.

There is no pressure evolved, and consequently the liquid does not issue with sufficient force to cause a spattering of the burning hydrocarbon upon which it may be poured. The result of the chemical reaction between the alum and the bicarbonate is a prompt evolution of carbon dioxide which, in contact with the liquorice solution, forms an exceedingly stiff and persistent foam. Such a layer of foam, containing an inert gas upon the surface of a burning liquid, cuts off all access of air, and combustion necessarily ceases. The temperature of the liquid may have reached a sufficiently high point, so that, through evaporation bubbles of the vaporised hydrocarbon rise, for a time, through the stratum of foam, and tongues of flame flutter over its surface. These soon cease, for simultaneously with the evolution of the carbon dioxide, there is a loss of latent heat, the temperature of the foam-yielding solution falls, and this, in turn, cools down the combustible liquid. The solution acts thus in a double manner as a protective agent.

Among the numerous tests to which the apparatus has been submitted by the heads of fire departments in Germany, the following, by the head of the Tanover department, may be mentioned. An iron vessel, five and-a-half by two and a-half feet in size, and four inches deep, received a charge of eighteen gallons of benzine. Benzine was likewise poured on the ground where the vessel rested. The liquid in the vessel, and outside the same, was lighted, and allowed to burn for three minutes. The contents of two foam extinguishers were then allowed to flow over the whole. Combustion was promptly arrested. The superincumbent layer of foam was then removed, and the benzine lighted anew. The attempt was now made to extinguish the flames by means of water, first with a simple, portable house extinguisher, and then with the use of the city water supply, issuing from a two-inch hose. In neither case could the fire be extinguished. On the contrary, the area of combustion was rapidly extended, until it covered over forty square yards. It was then necessary to discontinue the use of the hose, on account of the danger to the buildings surrounding the court in which the experiment was conducted.

The success attendant upon this and similar tests has led to the conviction among German authorities on protection against fire, that the foam extinguisher is capable of rendering valuable service in all places where combustible liquids are stored, and especially in automobile garages, and motor yachts. The use of liquid fuel for rapid locomotion by land, water, and air is extending so rapidly that the new protective, it is said, will meet a distinct need.

Complete plans for the new Quebec Bridge have now been submitted for the approval of the American Government. The failure of the partly erected structure having been caused by the insufficient strength of the lower chords, it is proposed to substitute a proportion of nickel steel for the carbon steel previously used. It is asserted that if bridges are to be constructed of a greater span than 2,000ft., nickel steel must be adopted.

* * *

Mr. Alfred Walter Bayes, A.R.E., who was killed by a motor-car accident, was born in 1832, and had intended to become an architect, but was attracted to the pictorial side of art. His scenes from the history of the Pilgrim Fathers, such as "The First Sunday in New England," and "The Departure of the Mayflower," became very popular. Mr. Bayes had contributed to the Royal Academy since 1858, and he was an Associate of the Royal Society of Painter-etchers. He had been for some time engaged on etchings of "Old and Vanishing London."

Correspondence.

[*The Editor declines responsibility for the statements made by correspondents.*]

Middlesbrough Library Competition.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—At the suggestion of certain architects, the memorial and letter in reference to the above competition was sent to the Competitions Committee of the R.I.B.A., the hope being expressed that they would take up the matter strongly. To this they replied as follows:—

"The Competitions Committee have considered the objections to the assessor's award raised in your memorial to the Middlesbrough Council.

"It appears that the most serious objections to the award in your views are:—

"(1) The position of the lending library.

"(2) The area devoted to patents library, etc.

"The other objections do not appear to be of any great importance.

"With regard to the first, the committee is of opinion that the clause in the instructions defining the position of the lending library is somewhat ambiguous, but it does not seem to necessitate its actually abutting on the dwelling-houses. The suggestion is that it should be on that part of the block of land adjoining the dwelling-houses.

"Your second objection as to the area of the patents library seems to be due to a misapprehension of the schedule of accommodation given in the instructions. The 1,739ft. required includes corridors, lavatories, etc.

"An examination of the successful plan will show that the door from the newsroom to the entrance hall is a private passdoor, and not for the use of the public.

"The Competitions Committee consider that when an assessor has been regularly appointed it would be well to bring any objection to the award before them in preference to approaching the promoters directly."

To which we replied disagreeing with their interpretation of the conditions, and laid the whole of the correspondence before the president of the R.I.B.A., at the same time sending a copy of same to the "Architect," "British Architect," "Builder," "Building News," and "Builders' Journal," all of whom published it in last week's issue, with the exception of the "Builder," which had an article in support of the protest.

The president's reply, per the secretary R.I.B.A., was as follows:—

"The president of the Royal Institute of British Architects desires me to thank you for your letter. He has very carefully considered the terms of the protest which you have sent to him, together with the conditions and the successful design, and he has come to the conclusion that the decision arrived at by the Competitions Committee of the Royal Institute is a sound one."

We have replied as follows:—

"We have to acknowledge your letter of the 26th inst., but would point out that you appear to have misunderstood our intention in forwarding you the protest in question.

"This was sent to you, as head of the Institute, with the object of having the matter thoroughly investigated by the Council of the Royal Institute, and not by you personally (see clauses 3 and 4 in our letter), and we shall be obliged if you will be good enough to bring the matter before your Council at the earliest moment."

Yours faithfully,

HOSKINS AND BROWN, Court Chambers, Darlington,
KITCHING AND LEE, Houndgate Chambers, Darlington,
W. H. BOURNE, A.R.I.B.A., Houndgate Chambers, Darlington.
June 29th, 1909.

At a recent meeting of the Council of the Quantity Surveyors' Association, Mr. H. T. A. Chidgey was elected president for the ensuing year, and Messrs. S. Chatfeild Clarke, and J. S. Parmenter, vice-presidents.

BIRMINGHAM UNIVERSITY. SIR ASTON WEBB, C.B., R.A., AND E. INGRESS BELL, F.R.I.B.A., ARCHITECTS

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
July 9	PUBLIC BATHS, WOOD GREEN Architects desirous of competing are invited to send full particulars of any recent public baths designed by them, the erection of which they have supervised, stating general accommodation, cost, etc., to W. P. Harding, Clerk to the U.D. Council, Town Hall, Wood Green, not later than July 9th. From those thus applying a selection of not more than 15 Architects will be made, who will be invited to compete on certain conditions and particulars. Premiums of £52 10s., £26 5s., and £15 15s. will be awarded to the designs placed by the Assessor as first, second and third. Assessor: Mr. A. Hessell Tiltman, F.R.I.B.A. Cost not exceeding £8,000. The Council reserve to themselves the right of selecting from the premiated designs the one eventually to be erected.
July 9	STOKE-UPON-TRENT. Additions to Town Hall including large hall to seat 3,000 people, police court, etc. Premiums of £100 and £50 for second and third designs respectively. Assessor nominated by Pres. R.I.B.A. Conditions and particulars from Jno. B. Ashwell, Town Clerk, Town Hall, Stoke-on-Trent,
July 17	NEW PUBLIC BUILDINGS, BURSLEM. The Architect whose design is placed first by the Assessor will be appointed to carry out the work. Premiums of £100 and £75 to authors of second and third designs, respectively, Conditions and plan of site from F. Bettany, Borough Surveyor. Deposit, £2 2s., returnable on receipt of *bona fide* design.
July 19	WHITLEY BAY PUBLIC ELEMENTARY SCHOOL for 600 scholars, for the County of Northumberland Education Committee. *Limited to Architects practising in the County and in the City and County of Newcastle-on-Tyne.* Particulars and plan of site from C. Williams, Secretary to the Education Committee, The Moothall, Newcastle-on-Tyne. Assessor: W.H. Knowles, F.R.I.B.A., F.S.A.
July 30	GRIMSBY TOWN HALL EXTENSION. Estimated cost £26,000. Conditions of competition sent to any applicant on receipt of a stamped addressed foolscap envelope. Full particulars, schedule of requirements, plans of existing buildings, etc., on receipt of deposit £2 (cheques to be made payable to Frank Stephenson, Borough Treasurer), which deposit will be returned to those who send in designs, or if the whole of the particulars are sent back within ten days from the date of their receipt by the applicant. Premiums of £250, £150 and £100. An Architect of eminence will advise in conjunction with the Borough Engineer. Applications to be made to the latter, H. G. Whyatt, Assoc.M.Inst.C.E., Town Hall, Grimsby.
July 31	LAYING OUT ESTATE AT EASTWOOD, RENFREWSHIRE. The patrons of the Royal Incorporation of Hutcheson's Hospital, Glasgow, invite competitive designs for laying out for feuing and building their lands of Thornliebank, containing about 195 acres. Particulars, conditions, and skeleton plans from the Chamberlains to the Hospital, Hill and Hoggan, 194, Ingram Street, Glasgow, to whom designs are to be sent. Premiums, £100, £75, £50, and £25 for the first four designs, *which will become the property of the patrons, who will not be bound further to employ the authors.* Deposit, £3 3s.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.

New Library, Liscard.

The assessor in this competition, Mr. G. H. Willoughby, F.R.I.B.A., of Manchester, has given his award as follows:—First, Messrs. R. B. MacColl and G. E. Tonge, Bolton and Southport; second (bracketed), Mr. J. R. Earnshaw, Manchester; Messrs. Packer, Drewitt and Drewitt, Southport; Messrs. Appleyard and Quiggin, Liverpool; Messrs. Deacon and Horsburgh, Liverpool; Messrs. Sproat and Warwick, Liverpool.

BIRMINGHAM UNIVERSITY.

The new University at Birmingham, which will be opened by the King to-morrow (Thursday, July 7th), has, over the main entrance, statues of Shakespeare, Plato, Virgil, Michael Angelo, Faraday, Darwin, Newton, Beethoven, and James Watt—a sufficiently catholic, not to say heterogeneous, collection, representing the very varied interests and activities of the University. The floor of the dignified entrance hall is in dove Pentelikon and Sicilian marble, and the walls are adorned with Breche Violette columns, having grande antique bases and skirtings, and statuary caps. The columns support a circular promenade, above which is the dome with whispering gallery. The buildings comprise the following blocks: Mining and metallurgy, civil and electrical engineering, mechanical engineering, chemistry, physics; and there are foundries, forges, buildings for large furnaces, and experimental plant in connection with the metallurgical department, and an experimental mine. The clock tower, which is 325ft. high, and in which there is a peal of bells, is to be called the Chamberlain Tower, and is a conspicuous landmark for miles round.

The buildings may be thought to lack something of the grace and serenity of the older university buildings in the kingdom, but it must be remembered that, as indicated in the description given above, Birmingham University will fulfil many purposes that were undreamt of in constituting and designing the older seats of learning. Its objects are largely utilitarian, and the buildings certainly express their purpose, and thus fulfil one of the cardinal conditions of good design.

The architects are Sir Aston Webb, C.B., R.A., F.R.I.B.A., and Mr. Edward Ingress Bell, F.R.I.B.A., the chief contractor being Mr. Rowbotham.

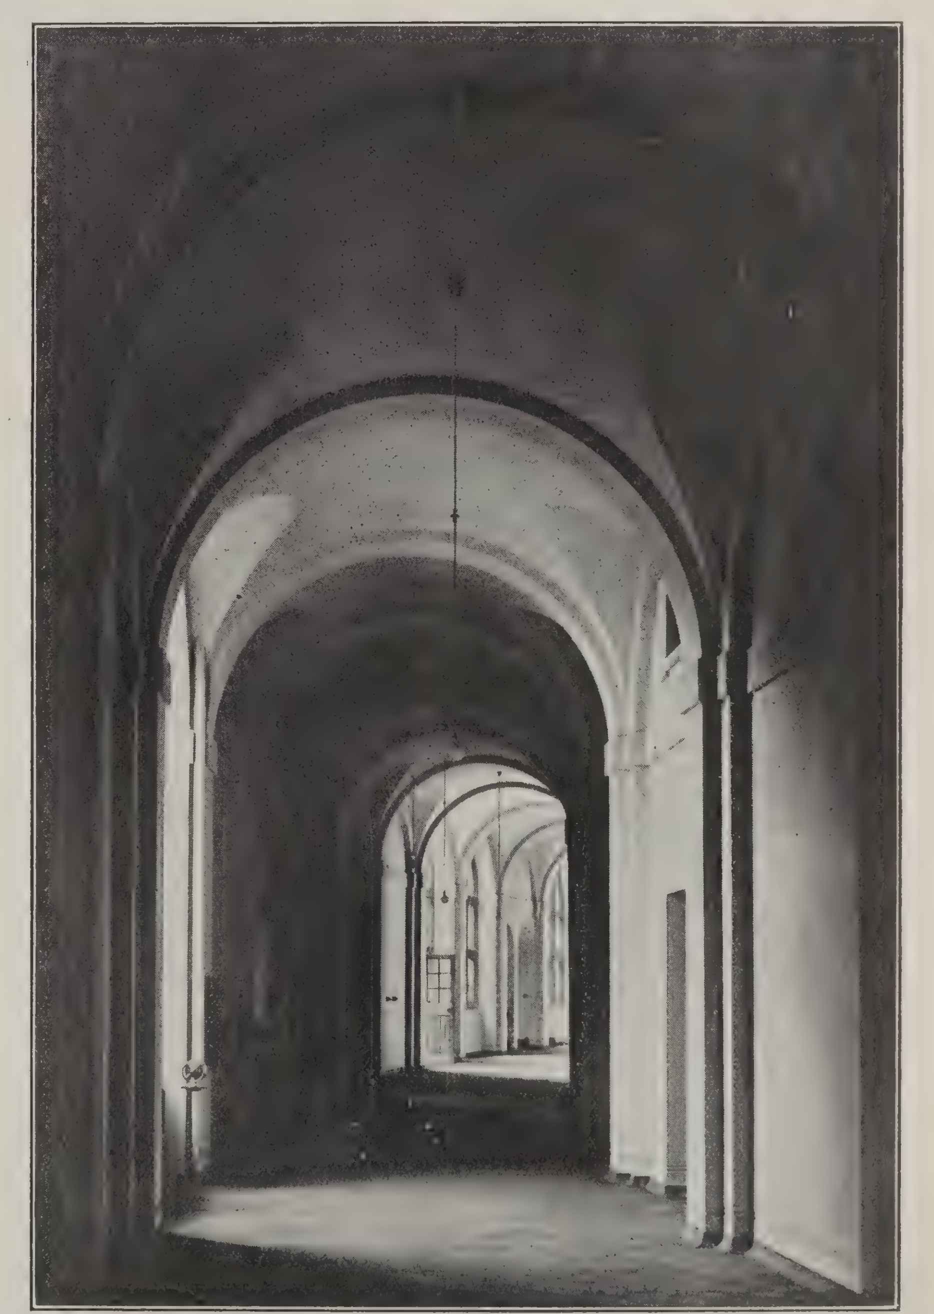

Photo: Topical.

BIRMINGHAM UNIVERSITY, MAIN CORRIDOR. SIR ASTON WEBB, C.B., R.A., F.R.I.B.A., AND E. INGRESS BELL, F.R.I.B.A., ARCHITECTS.

In designing the main corridor, the Architects have avoided, on the one hand, the baldness of a mere passage, and, on the other, the tendency to ecclesiastical style that is exceedingly tempting. This corridor, however, possesses character of its own, and is of dignified and graceful proportions.

Photo: Topical.

BIRMINGHAM UNIVERSITY; ENTRANCE HALL. SIR ASTON WEBB, C.B., R.A., F.R.I.B.A., AND E. INGRESS BELL, F.R.I.B.A., ARCHITECTS.

The Entrance Hall forms a fitting introduction to the Great Hall opening out of it. The floor is paved with dove Pentelikon and Sicilian marble, the walls are adorned with Breche Violette columns with Grande Antique bases and skirtings and statuary caps. The columne support a circular promenade, and above is the dome with whispering gallery.

REINFORCED CONCRETE AND FIRE RESISTANCE.

Numerous fire tests have been made to determine both the resistance of concrete to actual test, and also the depth to which the reinforcement must be embedded to prevent its being damaged. The maximum depth of pitting observed by Mr. Leonard C. Wason in actual fire tests, where a temperature of 1700 degrees F. or more has been maintained for a period of five hours, has been in either walls or ceilings one inch to one and one-half inches. Also by the examination of actual conflagrations, such as that at Baltimore, and elsewhere, it has been apparent that the prearranged fire tests are more severe in the results shown by the structure than are actual conflagrations. Therefore, Mr. Wason argues, if we can protect the materials against damage in a prearranged test, they will stand any actual service. The consensus of opinion of engineers is that there should be at least one inch of concrete between the nearest point of a bar to the ceiling in panels, at least two inches below the ceiling in beams and girders, and also two inches of concrete outside the vertical bars in columns. In designing columns, it is common to figure only that area of column inside the vertical bars when hooped as carrying the load, or if hoops are omitted, and but light reinforcement is used to prevent bending stresses, to add an extra inch beyond that needed to carry the load all around the outside, which might be burned away without endangering the load-carrying capacity of the balance of the column within. If this is burned off, it can be plastered back, giving the column the same fire-resisting qualities as before.

Fire underwriters are always interested in knowing whether a particular structure is properly built or not. There is very little difference in outward appearance between one of perfect construction,—that is, in regard to size and placing of steel, size of members, etc.,—and one which is imperfect, and the only positively sure way to know is either by inspection or by test. There is no type of construction where more painstaking care in providing for every detail is necessary than in reinforced concrete. Concrete is either good or bad. There is no half-way about it, and if bad defects are manifested before the builder is clear of his work, he is usually the one to suffer. A precaution to assist inspection is the setting of the steel rigidly in place before pouring the concrete. The quality of the sand and stone used must be as carefully inspected as the cement, and a sufficiently rich mixture required to allow for inequalities of mixing and placing. With well-graded materials and first-class workmanship, a floor can safely be built with a mixture of one cement, three sand, and six stone, and, as insurance against uneven or poor workmanship, to-day it is quite common to specify a mixture of one, two, four, which, with thoroughly first-class workmanship, gives a stronger result than is necessary, and with ordinary or careless workmanship, ought to give a job which is still strong enough. Incidental to the process of construction while the concrete is still green, and much weaker than it will be with age, it is loaded frequently as heavily as it ever will be in actual service, and always it is loaded sufficiently to give a fair idea of its strength. Where there is any doubt of its strength, load tests can be applied. With these safeguards, in addition to those provided by the engineer, architect, or building department, the underwriters need have no fear that a building they are asked to insure is structurally weak.

As a basis for the proper regulation of construction, Mr. Wason, himself an American, can offer nothing better than the building code recently perfected by a joint committee of American Society of Civil Engineers and other societies, and approved with slight changes by the National Association of Cement Users (U.S.A.).

The other types of fireproof construction which are coming into competition with reinforced concrete are—structural steel encased in concrete (and this, when thoroughly encased from a fireproof standpoint, is similar to an all-concrete building); structural steel frame encased in terra-cotta; and, to a small extent, plaster of Paris and brick have been used in fireproofing steel, but not sufficiently to be worthy of much comment. Thoroughly well-laid brickwork is a good protection to columns, but when cast as arches between beams, it leaves the bottom flange exposed, which is a serious defect. Actual conflagrations have conclusively shown that terra-cotta is not so perfect a fire protection as concrete. This is, in Mr. Wason's opinion, largely due to the fact that its coefficiency of expansion is high, so that it expands to such an extent that when confined between the beams it is crushed, the lower member falling and thus weakening the floor. It is also more susceptible to a combination of fire and water, being to some extent brittle, and cracking when a cold stream strikes a hot surface.

Before concrete will disintegrate when exposed to fire, the large amount of moisture chemically combined in the setting of the cement, being 20 per cent. or 25 per cent. of its weight, has to be driven off by heat, and then the vapour thus driven off has to be evaporated from the pores of the concrete before it becomes sufficiently hot to crumble. The slowness of evaporating this vapour is probably the cause of concrete resisting extremely high temperatures for the brief period of a few hours, while a much lower temperature, if long continued, would ultimately disintegrate it. Cement, Mr. Wason asserts, will resist 500 degrees F. for an indefinite period, while a continuous temperature of over 700 degrees F. is disastrous. The cement coating of the stones of the concrete will resist the attack of fire so long that it is of less consequence whether the stone can be damaged by the fire or not. Thus pure limestone is a most excellent aggregate, and will not decompose until after the cement has done so, and after the cement has gone it is immaterial what aggregate is used, as the work has then failed anyway.

Regarding the cost of this type of construction as compared with others, the large use has proved conclusively that it will compete, because the item of cost is considered paramount in 99 out of every 100 structures. For large buildings the structural frame is almost always cheaper than the steel. Thin curtain walls cannot be built as cheaply, on account of form work, which is constant for a thin wall as well as for a thick one; but if the wall must be 16ins. or more in thickness, concrete is cheaper than brick. In small structures, such as dwelling houses, concrete is materially more expensive than brick or wood, because the form work is more irregular, and because of the greater expense of supervision. This is why it is not commonly used in small dwellings, and probably will never be much used. It has been used, and can be economically used, for large dwelling houses, especially those of simple design, where the form work is nearly as easy of execution as in an office building or mill.

Notes and News.

The first concrete building erected as a private residence in America is, it is believed, that built for the Hon. William Ward at Portchester, N.Y. It was begun in 1875, and completed in 1877. The architect was Mr. Robert Mook of New York. Some of the floors and ceilings were made of reinforced concrete, and this was thirty-four years ago!

* * *

The octocentenary of the building of Southwell Minster was celebrated last week by a diocesan service of commemoration and thanksgiving. The sermon was preached by the Archbishop of York, eighty-eighth in the line of bishops and archbishops, of whom Thomas of Beverley, who directed the building of the Minster, was the twenty-eighth. The date of the commencement of the work is lost, and it was decided to hold the commemoration on the anniversary of the consecration of Thomas of Beverley to the See of York, June 27th, 1109.

* * *

The Northern Architectural Association, of Newcastle-on-Tyne, will hold their annual excursion on Wednesday, July 14th, when Selby and the neighbourhood will be visited. Of course, the Abbey Church will be included, and by the courtesy of Mr. J. Oldrid Scott, F.S.A., the architect for the restoration, the party will be conducted over the work. The party will afterwards drive to Hemingborough Church, which is one of the most interesting in Yorkshire.

The Council of the Royal Sanitary Institute have appointed Mr. Henry Adams, M.Inst.C.E., F.S.I., etc., to represent the Institute at the conference which is being organised by the Engineering Standards Committee to consider the desirability of a standard being adopted for stoneware, fireclay, and other similar pipes.

* * *

The Building Acts Fire Escape Co. have asked us to state that, in order to obtain better facilities for handling the increasing business with which they are being favoured, they have removed from 4, Southampton Row, to 9a, Little James Street, John Street, W.C.

* * *

Mr. R. Stenning, President of the Surveyors' Institution, Mr. J. Carmichael, Past President of the Institute of Builders and the London Master Builders' Association, and Mr. E. B. Ellington, Vice-President of the Institute of Mechanical Engineers and Councillor of the Institute of Civil Engineers, gave evidence on June 28th against parts of the London County Council's General Powers Bill, which is being considered by a Committee of the House of Commons. Owing to the rapidly increasing use of steel frames for buildings, it has been complained by architects, builders, and other persons, that the regulations prescribing the thickness of outer walls are unduly exacting where structures with metal skeletons are concerned. The Bill seeks to meet this objection, but it also proposes to extend the Council's power of regulation to inner walls, and this plan is resisted by the Royal Institute of British Architects, the Surveyors' Institution, the Institution of Civil Engineers, and other bodies. They also object to the insertion of regulations in the Bill, as they contend that such an arrangement would be a bar to the adoption of improvements, and they urge that any regulations made by the County Council should be submitted to the Local Government Board.

Coming Events.

Thursday, July 8th.
London Master Builders' Association, 31 and 32, Bedford Street, Strand, W.C.—Special Council Meeting, 4 p.m.

Wednesday, July 14th.
Northern Architectural Association, 6, Higham Place, Newcastle-on-Tyne.—Annual Excursion, Selby.

Thursday, July 15th.
London Master Builders' Association.—Organisation Committee Meeting, 2.30 p.m., and Council Meeting, 4 p.m.

Monday, July 26th.
Builders' Benevolent Institution.—Annual General Meeting, 4.30, and Committee Meeting, about 5 p.m.

GUILD OF ARCHITECTS' ASSISTANTS.

A well-attended meeting of the Guild of Architects' Assistants was on June 18th held at Cardiff, in the New Law Courts, designed by Messrs. Lanchester and Rickards, to consider the formation of the Guild of Architects' Assistants, Mr. Lumsden presiding.

The Guild of Architects' Assistants was, as our readers are aware, recently formed in London, the object being to remedy certain discontents that have been growing more and more acute in recent years, and have chiefly arisen from the lack of co-ordination and unity between practising architects and their assistants. The object is to protect the interests of properly qualified assistants from unfair competition, while securing for practising architects the advantages of knowing that they were only engaging qualified men, and at the same time uniting both parties in an endeavour to further the interests of the profession generally.

Mr. E. J. Dixon, A.R.I.B.A., London, founder of the Guild, delivered an address in favour of establishing a branch of the Guild for South Wales and Monmouthshire. He pointed out the practical advantages of unity, saying that the days when the principal took a real interest in his pupils were past. He referred also to the architectural assistants turned out by the schools, colleges, and even the universities, without any attempt to regulate the supply.

The assistants must combine for their own support, and so be able to insure themselves against the many and various difficulties that arose in the course of their business. The benefit gained by mutual help would be of immense advantage to the rank and file of the profession. For the great majority of the assistants, architecture was first and foremost their means of gaining a livelihood, and some steps ought to be taken to render that livelihoood less precarious than was at present the case.

The Guild could act in a variety of ways for the benefit of its members. A principal had his remedy against an incapable or fractious assistant, but the assistant had no remedy in those cases where he was at the mercy of an unscrupulous employer. The Guild would have to undertake cases of this kind, first by friendly remonstrance addressed to the principal, and then by such other means as the nature of the case might suggest.

Then an employment bureau would be formed, and an allowance made to those out of a berth. Endeavours would be made to organise a system of registration on a large scale, so that the central body or local branches would be able to place many in situations who at present were unable to get in touch with the work for which they were fitted.

Statistics would have to be obtained in all centres as to the number of assistants, and the percentage of unemployment, before any definite unemployment scheme was adopted; but the tentative proposal was to pay a

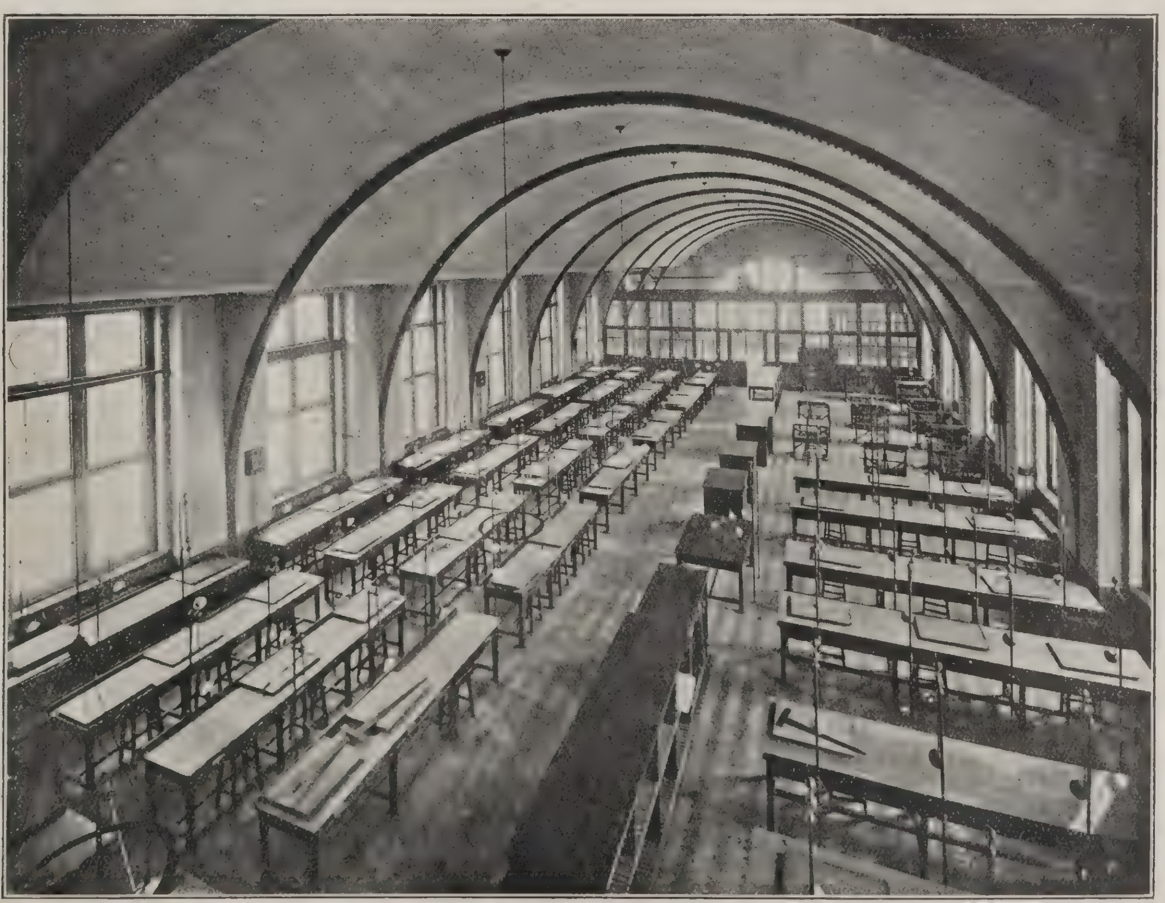

Photo: Topical.

BIRMINGHAM UNIVERSITY: DRAWING OFFICE IN MECHANICAL DEPARTMENT. SIR ASTON WEBB, C.B., R.A., F.R.I.B.A., AND E. INGRESS BELL, F.R.I.B.A., ARCHITECTS.

In the Mechanical Department architectural effect has been wisely subordinated to utility; and the Drawing Office here shown has the obvious merit of being exceedingly well-lighted.

thirtieth of the salary to the funds, and receive a half of the salary when unemployed.

There was also the question of the graduation of salaries, which undoubtedly bristled with difficulties, yet he believed it was far from being impossible of solution. Much more could be done by the grading of assistants into their respective spheres as designers, draughtsmen, constructionists, etc., and he had no doubt that with the co-operation of employers much could be accomplished to remedy a state of affairs under which some of the best men in the country were working for salaries no larger than the wage of an artisan.

He also referred to a scheme of education, pointing out the anomalies of the present examination system. Finally, he invited all to do their best to bring the Guild into active operation, and to see that it did not fail for lack of energy. There was no body at present dealing exclusively with the interests of assistants, who were fast becoming a most important section of the profession; and it was for the Guild to fill up this gap, and unite for protection and advancement.

An animated discussion then took place, in which several points of interest relating to the constitution of the branch and the scope of its work were satisfactorily answered by Mr. Dixon, and the following resolution was thereupon adopted:—"That this representative meeting of architects' assistants, supported by several well-known local architects, recognising the urgent need of combination and union in order to further their professional interests, resolves that a branch of the Guild of Architects' Assistants for South Wales and Monmouthshire should be formed in Cardiff, and that a committee be forthwith appointed for that purpose."

The Provisional Committee was then reelected, with power to co-opt others, Mr. S. Bowen Williams, of 110, Miskin Street, Cardiff, being appointed hon. secretary.

BRIGHTER PROSPECTS FOR THE BRICK AND TILE TRADES.

The season of early summer used to be one of the busiest for the brickmasters, and from June on to the end of October the demand increased. The building trades were generally in full swing, as well as many large contracting enterprises, and railway extensions and widenings swelled the demand. Notably was this the case while the Great Central Railway was being constructed. All other railways were also large users of blue and brindled bricks, rival railways were then keenly competing for ascendancy, and numerous branch lines were made in order to reduce distances and accelerate transit.

Now, however, the rivalry seems to have subsided. The boom in branch lines has ceased. Attention, however, is being devoted to the widening of existing lines, and this, of course, implies the occasional enlargement of stations, and the making of wider viaducts, bridges, and tunnels. Railway engineers have a profound faith in blue and brindled bricks, but in specifying them they leave the contractors a free hand to buy in the best markets. North and South Staffordshire are the largest producers of this class of clay goods; and although the brickyards in those districts are not as brisk as formerly, they are enjoying the lion's share of steady and continuous demand. Profits, however, are lower than formerly. It used to be the custom of nearly all firms to issue periodical printed price-lists, but for some time now that practice has been abandoned, and it is the rule to quote only on application, and according to the quantities needed for specific contracts. It is now the rule to quote nett prices, both at the works, and inclusive of delivery by road, rail, or water, and the abolition of discounts has made the terms much more satisfactory to the builders and contractors. The system saves much trouble to all parties, and renders the quotations, accounts, and book-keeping more clear and simple. Railway companies never allow discounts, and universal abolition would certainly simplify business. The railways issue their accounts at the end of the month, and require payment before or by the end of the month after, and the brickmasters, having adopted this practice, have not experienced much difficulty in carrying out the new system.

The demand for best-pressed blues and reds for facings has somewhat declined, terra-cotta having come more into use, especially for such buildings as free libraries, science and art institutions, and technical and other schools; but common reds, browns, and brindles, are in full demand. There are some big undertakings projected that will inevitably, if carried out, create greater prosperity for the makers of blue and brindled bricks. Sir John Jackson, in giving evidence in London before the Royal Commission on canals and waterways, on the question of a canal for sea-going vessels and battleships between the Clyde and the Forth, via Loch Lomond, estimated the cost at £20,000,000. The canal would probably be used by German vessels from Hamburg to New York, owing to the saving of time that it would enable them to effect. The Scotch manufacturing districts, however, would benefit largely from this great waterway. The contract for the construction of a huge dock at Rosyth has already been let to the firm of Easton, Gibbs, and Son, of Westminster, and they will very soon be placing their orders for materials, including Staffordshire bricks. Some millions of blues and brindles will be used. Messrs. H. Lovatt, Ltd., builders, Wolverhampton, have secured a large contract from the Great Western Railway for the further extension of that company's station at Snow Hill, Birmingham. Another waterway scheme that is mooted will, if carried out, infuse new life into the South Staffordshire and Midland trades. Sir John Wolfe Barry is conducting, on behalf of the Royal Commission on Canals and Waterways, an inquiry into a proposal to deepen the waterway from Gloucester to Worcester, and the canal from Worcester to Birmingham, to a sufficient extent to take barges carrying 100 tons and upwards. This will admit of manufactured goods from the Midlands being brought down to Cardiff for shipment, and enable timber, grain, and other importations into Cardiff to be transported to the Midlands. The scheme, if carried out, will cost £2,000,000. The new Naval docks to be constructed along the east coast will require millions upon millions of blue and brindled bricks, and will give a much desired impetus to the brick trades.

Our railways have for a long time shown great consideration to the brick and tile industries, having for many years ceased to exact their maximum tolls for bricks; and some of the permanent rates are exceedingly low. From South Staffordshire and East Worcestershire, for instance, to London, the rate for 5-ton loads is only 6s. 3d. per ton, and the railway companies have generously met the makers for all large lots required for specially large contracts. They also show more liberality in dealing with claims for brittle goods broken in transit, while the charges for detention of trucks (demurrage) have been reduced to one-half.

A DECADE OF FIRE PREVENTION.

The British Fire Prevention Committee, which was founded on the occasion of the great Cripplegate fire of 1897, and which was incorporated in 1899, celebrated the tenth anniversary of its incorporation on May 24th and 25th, when a number of distinguished visitors, including several from abroad, attended its meetings.

The committee's primary object during the last ten years has been to deal with the protection of life and property from fire by the adoption of preventive measures, and, during that period it has favourably influenced the reduction of the possibilities of fire, and of the spread of fire.

The greater knowledge of building materials and appliances obtained by scientific independent tests at the committee's testing station has done much to obtain a better understanding of the value and also the limitations of different methods of construction and equipment, whilst considerable influence has also been exerted by the committee in guiding building and fire service legislation in directions where it is most effective to prevent loss of life and loss of property.

Probably the most notable event in the committee's career was the large International Fire Prevention Congress of 1903, and the arrangement of the technical exhibits at the Fire Exhibition that was held on that occasion at Earl's Court. No fewer than 800 delegates attended the Congress, including more than 200 from abroad.

Other notable events were the arrangement of special commissions, comprising members of the committee who are instructed to visit various foreign countries and report on the subject of fire preventive legislation, and fire preventive arrangements generally, on the Continent. In this manner Austria, Hungary, Italy, Switzerland, and South Germany have been visited, and North Germany is being visited this year. Illustrated reports were issued dealing with these journeys, and were at the disposal, not only of members of the committee, but of the various public authorities concerned.

Another special commission that was appointed was that to deal with concrete aggregates. This commission has already published an interim report, but its final report will be dependent on the extent of the tests that can be undertaken with concrete aggregates according to the amount of funds available for this enquiry.

The reports issued by the committee to its members number 140, and comprise a comprehensive survey of the subject of fire prevention.

Of the founders who have held office on the Executive from the time of its incorporation to the present time should be mentioned Mr. Edwin O. Sachs, F.R.S.Ed. (chairman); Mr. Ellis Marsland (hon. secretary), and Mr. Max Clarke, F.R.I.B.A.

The objects tested by the committee since its formation numbered 160 to the end of last year, and it should be understood that the investigations into any one object sometimes requires as many as 20 or 30 testing operations. Notable tests have been those with large reinforced concrete floors, a series of fifty fire-resisting doors, fire-resisting glazing, and latterly also with safety devices.

Probably the tests that have had as great an influence as any on the development of the building industry were those with concrete and reinforced concrete floors, of which twenty have been under test, and several have been under test more than once. There were also tests with floor slabs of identical dimensions, but of different aggregates. Tests that have also materially influenced the development of fire preventive measures are those with fire-resisting glass. The wire glazing was under test on seven different occasions, and the electro glazing on five occasions.

The whole of the funds required for the establishment of the committee's testing station, and the execution of its work, have been raised voluntarily. More than £20,000 has been expended in ten years on the work of the committee, and the whole of the services of the committee and their officers are rendered voluntarily, members as a matter of fact even bearing all their own out-of-pocket expenses.

It is customary to decry the research work done in the United Kingdom as compared with the research work done elsewhere with the aid of Government grants and subsidies, but the British Fire Prevention Committee's testing station has so far not been rivalled in any other country, although imitated in the United States, France, and Germany, with the aid of Government funds.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himsel of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required fo answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable and it must be understood that both question a reply will, as a rule, be published in these columns.

Truss for Church Rcof.

GLASGOW.—"J. W. S." writes:—"What is your opinion of the church roof shown on the accompanying sketch drawing, and what is the easiest way to get sizes of the various timbers in same? Also, could you name a good book or books on estate management?"

The truss submitted would be a novel form, but not a particularly desirable one, as it would take rather more timber than usual, and would want great care in jointing and bolting. A single 12in. by 6in. timber would be ample for the tie-beam and also for the principal rafters; the truss being made 6in. thick, all the members may be flush on the two faces. The purlins need not be more than 9in. by 6in. For books on estate management, see Burn's Outlines of Estate Management (Lockwood, 2s. 6d.), Henderson's Young Estate Manager's Guide (Batsford, 4s.), Stephenson's Repairs: How to Measure and Value them (Batsford, 3s.), Greenwell and Curry's Rural Water Supply (Batsford, 4s.), Everyday Uses of Portland Cement (Associated P.C. Manufacturers, Portland House, Lloyd's Avenue, London, E.C., 2s. 6d. HENRY ADAMS.

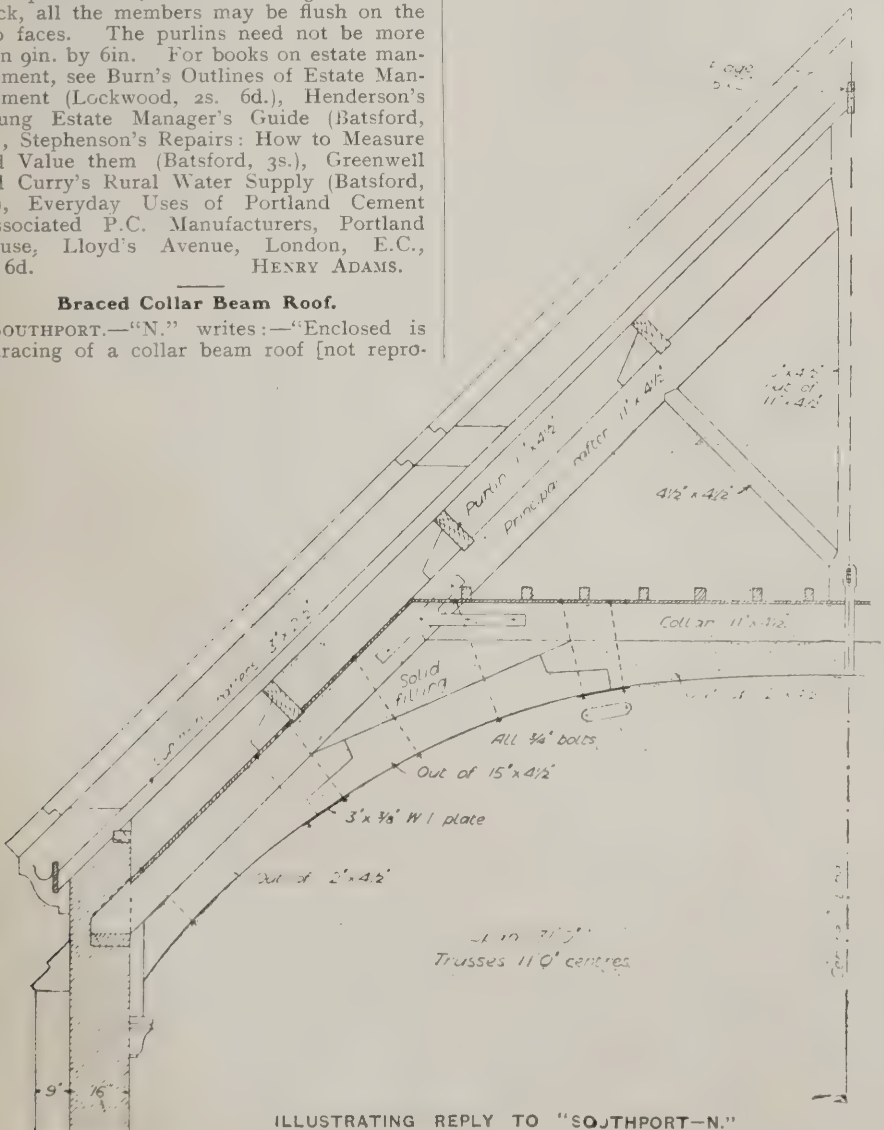
Braced Collar Beam Roof.

SOUTHPORT.—"N." writes:—"Enclosed is a tracing of a collar beam roof [not reproduced]. Will you please let me know whether you consider it is of safe construction?"

The accompanying illustration shows the truss proposed, with the suitable scantlings, joints, and bolts

HENRY ADAMS.



ILLUSTRATING REPLY TO "SOJTHPORT—N."

Load on Channel Section.

LONDON, S.W.—W. H. L. writes:—"How would you calculate the safe distributed load that could be put upon a 15in. × 4in. × 41.94lbs. R.S. channel, with a span between supports of 20ft.? What would be the numerical value of the moment of inertia for this section? The load comes on the flanges."

The moment of inertia of a 15in. × 4in. × 41.94lb. about an axis parallel to the flanges is 377.0in. units.

$$\therefore \text{section modulus} = \frac{3\cdot77}{7\cdot5} = 50\cdot27 \text{ inch units.}$$

Then adopting a working stress of 7 tons per sq. in.,

$$\text{Safe B.M.} = \frac{50\cdot27}{7} = 7\cdot18 \text{ inch-tons.}$$

$$\therefore \frac{WL}{8} = 7\cdot18.$$

$$\frac{W \times 20 \times 12}{8} = 7\cdot18.$$

$$W = \frac{7\cdot18 \times 8}{20 \times 12} = 2\cdot4 \text{ tons nearly,}$$

i.e. nearly 5 cwt.

A.

Steel and Concrete Floor.

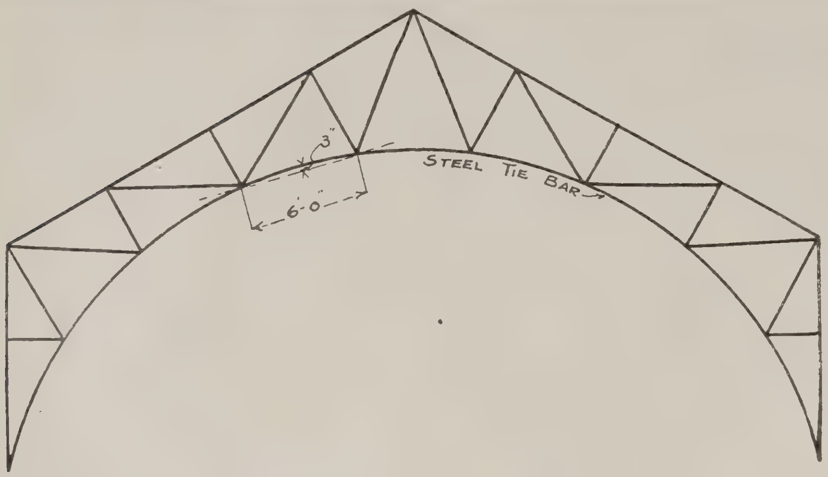
LONDON, W.C.—G. G. L. T. writes:—"In the construction of a steel and concrete floor, a 6in. by 3in. rolled steel joist is to be connected to the main joist (18in. by 7in.) in the position shown in the accompanying sketch [not reproduced]. The small joists only resting on the angles, there would appear to be the danger of their becoming dislodged, especially when the concrete is being rammed in."

In the writer's opinion, the small joists should be fixed in position before the concrete is rammed in. Angle cleats formed of the 3in. × 3in. angle would be satisfactory, or the joists might be just bolted down to the angles. In the latter case, care should be taken to see that the two ⅝in. rivets would be enough to carry the shear. This depends on the spans and loads, but in most cases they would be enough. A.

Stresses in Curved Tie-bar.

SCOTLAND.—FIFER writes:—"(1) Please explain the correct method of calculating the sectional area of the curved tie-rod shown in the accompanying sketch: assuming that the stress in the bar is 20 tons, and the deflection from a straight line joining the ends of bar is 3 inches. (2) Does the same method apply to the curved rafter in a segmental roof, where the stress is of compressive nature instead of tensile?"

(1) The stresses in a curved tie-bar carrying a load W and with a deflection X are given



ILLUSTRATING REPLY TO "SCOTLAND—FIFER."

by the formulæ ·

$$\text{Max. stress}=\frac{W}{A}\left(1+\frac{xd_t}{k^2}\right)\ldots\ldots\ldots(1)$$

$$\text{Min. stress}=\frac{W}{A}\left(1-\frac{xd_c}{k^2}\right)\ldots\ldots\ldots(2)$$

where

A = cross-sectional area of bar,
d_t = distance from centroid to edge of section nearest to chord,
d_c = distance from centroid to edge of section farthest from chord,
k = radius of gyration of section about centroid.

In the present case, assuming that 7 tons per sq. in. is the safe stress,

$$7=\frac{20}{A}\left(1+\frac{3d_t}{k^2}\right)$$

From this the area cannot be obtained directly, but the necessary section must be obtained by trial; e.g., take 2 6×4×½ unequal angles placed with their long legs upwards.

From tables we see that $A = 2 \times 4.75 = 9.50$; $d_t=1.96$. $k^2=\frac{I}{A}=17.1=3.6$.

$$\therefore\frac{20}{A}\left(1+\frac{3d_t}{k^2}\right)=\frac{20}{9.5}\left(1+\frac{3\times 1.96}{3.6}\right),$$

$$=\frac{20}{9.5}\times 2.63=5.53 \text{ tons per sq. in.}$$

This section is therefore stronger than necessary.

Taking 2.5½×3½×½ angles, $A=8.5$, $d_t=1.85$, $k^2=\frac{12.8}{9.25}=3.01$.

$$\therefore\frac{20}{A}\left(1+\frac{3d_t}{k^2}\right)=\frac{20}{A}\left(1+\frac{3\times 1.85}{3.01}\right)=6.7 \text{ tons per}$$

sq. in. nearly.

This will be satisfactory.

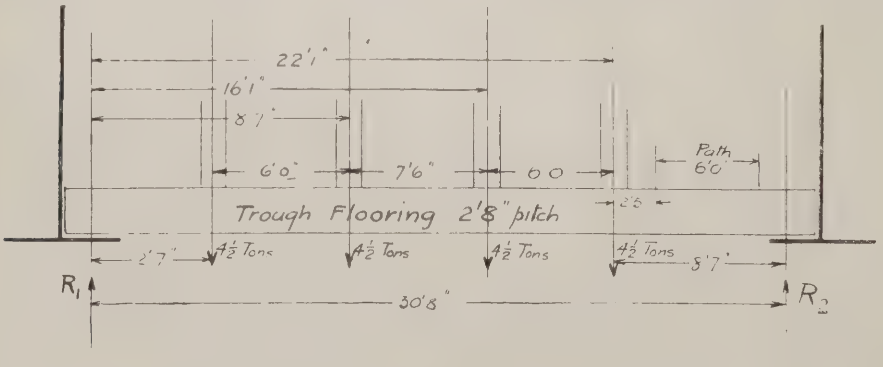
(2) The above method is applicable to the case where the force is compressive, with the exception that instead of a safe stress of 7 tons per sq. in., we must use the safe stress per sq. in. for the section considered as a strut. A.

Trough Flooring Design.

PROVINCES. — WINDSOR writes: — "Please clear up the following points in connection with the design of steel trough flooring: The section of troughing adopted in a given case is sufficiently strong to carry the dead weight of road material, and a crowd of people, on the whole area of the bridge. It is also strong enough to carry a 14-ton traction engine and train of loaded trucks with remaining area of bridge carrying a crowd of people; but in considering a case where two 14-ton traction engines will pass over the bridge, in opposite directions at the same time, it will appear theoretically (as will be seen by the enclosed calculations) that the troughing is much too weak, although the bridge in question has been subjected to such a test upon more than one occasion, and with apparently not the slightest injury to the troughing. I shall therefore be glad to have your views upon the calculations. I am not clear as to which method in cases 1 and 2 is the more correct theoretically, and whether it is wise in practice to allow such a margin as that shown beyond the safe working stress of 6½ tons per sq. inch.

"In case No. 1 the loads transmitted by the traction engines are treated as live loads, and the maximum BM in inch tons × 2 to bring the result to equivalent dead loads. In case No. 2, the loads transmitted by the traction engines are treated as loads which are equivalent in effect to those between dead loads and live loads suddenly applied, as in the case of railway engines, and multiplied by, say, 1½ to bring to equivalent dead loads."

The querist's calculations are not reproduced in detail, but one of his diagrams is here given. This query raises points upon which there is considerable difference of opinion among designers. With a working stress as low as 6½ tons per sq. in., some designers would not make any extra allowance for the fact that the load is "live," but this is not, in the writer's opinion, really satisfactory. In the present case it does not appear to be necessary to limit the number of troughs to 1½; a trough floor may be looked upon as a single beam, and, the loads given, two and a-half or even three troughs might be considered as carrying the load. The writer would therefore recommend dealing as in case 1, *i.e.*, taking equivalent dead load = 2 × live load, and taking 2½ troughs as carrying the load. Then with the above-given values of the bending-moment, the stress would come $=\frac{2202.35}{135.2\times 25}=6.2$ tons per sq. in., nearly. The actual length over which to spread the load is, of course, dependent upon the dimensions of the traction engine, but about 6ft. can be taken as satisfactory in most cases. A.



ILLUSTRATING REPLY TO "PROVINCES—WINDSOR."

Tie-rods to Hall Roof.

ELGIN.—SURVEYOR writes:—"Would the tie-rods shown in the accompanying sketch of a hall roof be of much service? If these are added, would it still be necessary to strengthen the buttresses?"

FIG. 1

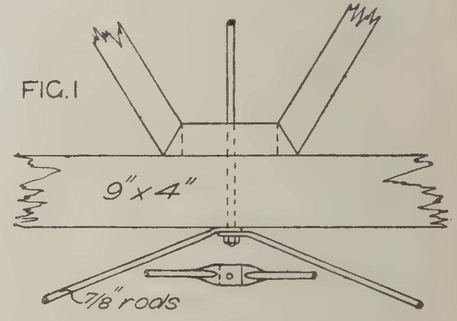


FIG. 2

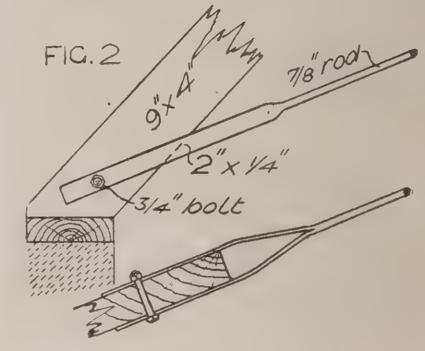


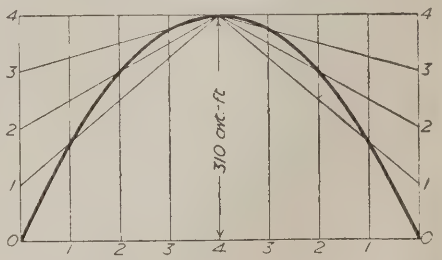
Tie-rods to a large collar beam roof are of great assistance in preventing thrust upon the walls. If they are put into this roof the additions to buttresses will not be needed. The tie-rods can be fixed as shown in Fig. 1 for centre and Fig. 2 for ends.

HENRY ADAMS.

Stress Diagram for Open Timber Roof Truss.

DUBLIN.—R. C., JUN., writes: "With reference to the reply to 'H.,' in your issue of May 12th, will Mr. Adams kindly explain how he obtained parabolæ as diagram of bending moment as shown in Fig. 4?"

Taking the right-hand lower curved brace, the direct tension is 388 cwt., and the versin between the straight line and curve is 0.8ft., giving the maximum bending moment in centre as 388×0.8=310cwt.—ft. The intermediate bending moments between the centre and ends vary as ordinates to a parabola, which is set off as follows. Upon the base given by the straight line joining the ends of brace, set off a central height equal to the maximum bending moment to any given scale, draw a complete rectangle, divide the base into say eight equal parts, and each side into half the number of equal parts, join up as shown, and the parabola will be drawn through the intersections.



HENRY ADAMS.

LONDON FIRE BRIGADE'S NEW CHIEF.

To the general surprise, the question of the command of the London Fire Brigade became the subject of controversy, whereas the public had expected that the appointment would be the simple matter of promoting the second officer, Mr. Gamble, F.S.I. As a leading authority on fire protective matters, and as an officer of seventeen years' standing in the London Fire Brigade, Mr. Gamble had richly merited the advancement; but the County Council, rejecting this simple solution, thought fit to advertise for candidates; and the Fire Brigade Committee, whilst recommending Mr. Gamble to the office, also put forward certain other names.

Photo: Topical Press.

LIEUT. SAMPSON SLADEN, R.N.
The New Chief Officer of the London Fire Brigade.

He joined the Fire Brigade on January 31, 1899, but is still on the active list of the Royal Navy. For assisting to save lives from the Italian steamship *Utopia*, Lieut. Sladen was awarded a medal and diploma by the Italian Government. On his first joining the Brigade he was appointed to the position of Third Officer, but in October, 1904, the title was altered to that of "Divisional Officer," and Lieut. Sladen was placed in direct charge for fire brigade purposes of the whole of the County of London north of the Thames, with the exception of that part included in the central district.

Thereupon it would appear that the General Purposes Committee of the London County Council, in their wisdom, deemed that the command should be vested in a naval officer, as if the whole of the management of the brigade and the whole of the fire protection of London were merely a question of naval discipline! They recommended a naval officer, Commander Cowper. So strongly was this General Purposes Committee bent on securing military or naval discipline, that they put forward as alternative candidates not the second officer, but the third officer, Lieutenant Sladen, formerly of the Royal Navy; and a Royal Engineer officer, Major Crookshank.

Needless to say, the general public of the metropolis interested in the subject—and, as a matter of fact, the Council as a whole—were dissatisfied with the action of the General Purposes Committee, and when their recommendation came forward it resolved itself into a question of voting as to whether the whole matter should be "referred back" or not. The result of the voting against this "reference back" was a small majority, obtained on a plain show of hands. That the matter was not referred back as it should have been as one would have expected, was due, we are afraid, to the entirely injudicious and untimely action of certain superintendents and firemen of the London Fire Brigade, who, thinking that they would do Mr. Gamble a "good turn," actually petitioned the Council for his appointment. Nothing could have been less in the interests of Mr. Gamble or in the interests of the brigade than this unwise action on the men's part, for every member in the Council who has had anything to do with military or naval matters naturally disliked the idea of a petition of this kind. To put it quite plainly, it was this unfortunate petition (of which Mr. Gamble and the other superior officers of the brigade had not the slightest cognisance), which ruined his claims.

Mr. Gamble having been thus unfortunately put out of court, it only remained for the Council to decide which of the three candidates put forward by the committee should be selected; and we think the Council acted rightly in selecting Lieutenant Sladen, who has had some ten years' experience of Fire Brigade work, and so had far greater claims than any stranger. We believe that the large majority by which this officer was finally selected was due in great part to the whole of the votes for Mr. Gamble having been transferred to Lieutenant Sladen; and we think this was also done rightly, for it would have been a set-back to the whole of the fire service of the country if a stranger had been allowed to step in at this stage. It would have meant cutting off the career of the junior officers of the brigade, and it would have been a kind of advertisement that scientific knowledge or experience were not wanted in fire brigade work.

Whilst sympathising most sincerely with Mr. Gamble, on the other hand, we are glad that, failing him, the succession should have fallen to Lieutenant Sladen.

During the time Lieutenant Sladen has held the position of Third Officer, he has taken the greatest possible interest in the technical aspects of fire protection. Building questions have been a particular study of his, and he has been actively interested in the scientific study of fire protection. It is to be hoped that his command will be thoroughly successful, and that the excellent relations that exist between the London Fire Brigade and the various fire service and fire preventive associations at the present time, may be maintained. Mr. Sladen enters his new duties and responsibilities with the good wishes of those who have the fire protection of the Metropolis at heart.

L.C.C. FIRE BRIGADE COMMITTEE.

The Fire Brigade Committee of the London County Council report that working drawings of the proposed new fire-station in Parnell Road, Bow, have been prepared, and that quantities should be taken out and lithographed at an estimated cost of £235. The Council had approved an estimate of expenditure on capital account of £2,400 in respect of the purchase of a site and the preliminary expenses in connection with the preparation of plans; but as the site cost £2,200, exclusive of costs, the balance of the estimate was not sufficient to cover the cost of the quantities. A supplemental estimate of £300 to cover the cost of the quantities and other preliminaries was therefore submitted to the Council. The committee think it undesirable that an estimate of the whole cost of erection of the station should be submitted at this stage. The committee also report that the external woodwork and ironwork at sixteen fire stations and eight street fire-stations, and the front appliance room doors at twenty-three fire-stations require to be painted this year, and that the expenditure, which is estimated not to exceed £1,189 11s. 3d., is provided for in the estimates for the current financial year. The work is to be executed by Messrs. Gladding and Co., under the jobbing schedule. A further recommendation is that expenditure not exceeding £111 be sanctioned for the purchase of 120 chemical fire extincteurs for the fire brigade; it being a rule that a chemical fire extincteur should be kept at each fire-station, and that two extincteurs should be carried on each motor fire-appliance. They cost £1 each, less 7½ per cent. discount.

ANNUAL CONGRESS OF FRENCH ARCHITECTS.

The thirty-seventh annual congress of French architects, which was held at Toulouse from June 20th to June 26th, appears to have been, at least from the social point of view, entirely successful. The meetings were held at the Hôtel d'Assézat, which is a building of considerable architectural interest. It was built about the middle of the sixteenth century, but has, of course, undergone many restorations. It is the favourite hotel of the learned societies of Toulouse.

The sittings opened under the presidency of M. Yvon, of Paris. The members of the Congress were welcomed by M. Feuga, representing the Mayor of Toulouse. The first matter under discussion was an elaborate report, prepared by MM. Bonpaix and Delaire, on the incidence of taxation with respect to the liberal professions, and its effect on architects. The chief grievances seem to be that architects are required to furnish the authorities, during January, with a full and particular account of their incomes during the year immediately preceding, the architects naturally requiring more time for the ascertainment of their earnings; and that the official inquiry into the architect's circumstances is inquisitorial and humiliating. The whole subject, however, assumed so much complexity that the meeting felt unable to deal with it, and expressed the view that the Central Society of Architects should make representations to the Fiscal Commission of the Senate.

The next question debated was that of the insurance of architects against professional risks. The nature of these risks may be inferred from the fact that several speakers held that, under a proposed system of mutual insurance, "honest and conscientious architects would be paying premiums for the sole benefit of those who were less scrupulous, who covered by the insurance, would not hesitate to produce careless work (*n'hésiteront pas à livrer un travail négligé*)." The Congress unanimously approved of the principle of assurance against personal risks, but rejected the idea of mutual assurance.

M. Frantz Blondel, President of the Provincial Association of French Architects, took the chair at the session of June 22nd, when M. Masquet introduced the subject of the organisation of apprenticeship in the building industry. He advocated a system in which the workshop training afforded by the employer should be supplemented by some special organisation which should superintend and systematise the instruction of apprentices. A desultory discussion, in which a good many more or less visionary and manifestly impracticable ideas were expressed—as, for instance, that parents being deterred from apprenticing their boys to an industry that made no provision for the aged workmen, the obvious remedy was to include in the apprentice's education a course of instruction in social economy, so that he might see clearly the necessity for thrift and foresight! Naturally, it was at this point that the sitting was adjourned for the day. At the resumption, M. Blondel deprecated any further appeal to the State. "We have," said M. Blondel in effect, "enough laws and by-laws. The real remedy does not lie in that direction." After an animated debate, the following resolutions were adopted: (1) That the architectural societies take the initiative in promoting the formation of societies for the development of apprenticeship in the building trades. (2) That the societies thus formed shall put themselves in communication with the chambers of commerce, general and municipal councils, employers' and operatives' organisations, and all other groups and individuals concerned, in order to obtain their moral and financial support, with the object of (a) organising the pre-apprenticeship conditions, either at school or otherwise; (b) subventioning the smaller employers to encourage them to take apprentices; (c) stimulating the apprentices by means of competitions with prizes and rewards; (d) assisting the young workmen to perfect themselves in craftsmanship by establishing courses of technical instruction. (3) That the syllabus in primary and higher elementary schools should be so modified as to give the chief attention to classes of manual instruction, design, modelling, woodworking, ironworking, and similar occupations. (4) That the law of 1892 with respect to the working-time of apprentices, and that of 1902 concerning hygiene, should be modified, with due regard to the proper limitation of hours for those of tender years. These views are almost identical with those enumerated at the recent Paris Congress, the chief difference being that those were of general application, whereas at Toulouse only the building trade was taken into consideration. The fact that architects should think it worth their while to take such an active interest in a question which the profession in this country would consider to be a purely family affair for the employers is rather a striking proof of the diverse footing on which the architects of the respective countries stand.

There was, of course, the usual round of visits to places of interest; and the inevitable banquets were held, respectively, at the Grand Hotel and in the Palais d'Orsay.

Works in Progress and Completed.

ABERAMAN.--The new Public Hall has been opened. It comprises a large hall to seat 1,400 people, a lesser hall to seat 400, eight committee-rooms for workmen and others, reading-room, lending library, ladies' reading-room, slipper and shower baths, swimming bath, billiard-rooms, and game rooms. It is lit by electricity. Mr. T. Roderick was the architect, and Messrs. J. Morgan and Son, Ltd., of Aberdare, the contractors. The cost was above £10,000.

ASHFORD (Middlesex).—A new residence is being built here in Reedsfield Road by Mr. S. Dinn, of 17, Cathnor Road, Shepherd's Bush.

ASHLEY DOWN.—A large mixed school, known as the Sefton Park School, is being erected from the designs of Messrs. W. V. Gough, F.R.I.B.A., and A. R. Gough, A.R.I.B.A., of Bridge Street, Bristol, and the general contractors are Messrs. G. Humphreys and Son.

BATH.—The additions to the Bath Royal United Hospital have been completed. The site was obtained by the demolition of four small shops, and the space obtained was awkward and cramped. The additions comprise an extension of the nurses' home; accommodation for the out-patients; and the provision of an isolation ward. The building, of four floors, is faced with Bath stone, and has a flat roof. Mr. E. Keene Oliver, of Bath, is the architect, and Mr. F. J. Blackmore, of Tiverton, W. Bath, the contractor. The cost is about £4,000.

BEN RHYDDING.—A new Wesleyan Church, to seat about 250, has been erected here at a cost of about £3,500.

BIRKDALE.—Messrs. Austin and Paley, Lancaster, are the architects for the extensions at St. John's Church, the original church being erected from their designs in 1889. The additions comprise a new north aisle practically the same as the present south aisle, the present temporary north wall of nave and chancel being removed, and an arcade of five arches substituted; a new entrance at the western end of aisle; a clergy vestry at the east end, and a choir vestry, 25ft. by 17ft., on north side, with separate porches and lavatories. The chancel screen will be continued under the new north arch. It is proposed to remove the organ to position of the present temporary vestry in south aisle, so as to allow of additional sittings. The total additional accommodation obtained is 186 sittings. The contractors for the work are Messrs. Duxfield Bros., of Southport.

BRIDGEND.—A new mission Church, to seat 250, has been erected here. Mr. A. Jenkins, of Blackmill, was the architect, and Mr. Philip Gayland, of Bridgend, the contractor.

CARDIFF.—The foundation stone of St. Luke's Church, Victoria Park, Cardiff, has been laid. The building, which has been designed by Mr. G. E. Halliday, F.R.I.B.A., is to seat 700 people, and the estimated cost is £3,500.

CASTLEFORD. — The new Secondary School in Cemetery Road, designed by Mr. W. S. Braithwaite, of Leeds, and costing over £12,000, was opened last month. The school comprises assembly hall, twelve class-rooms, manual instruction room, domestic science room, committee-room, headmaster's and assistants' rooms, bicycle rooms, gymnasium and dining-room, chemical and botanical laboratory, lecture theatre, optical room, physics and geographical laboratory, elementary and advanced art rooms. The grounds are laid out for tennis court, hockey, cricket ground, and school gardens.

DARLASTON.—A new Central Primitive Methodist Chapel in Slate Street is now being erected. The new building will hold about 700 people, and cost about £3,300. Mr. C. W. D. Joynson, of Wednesbury, is the architect.

DINGWALL.—The new U.F. Church has been erected at a cost of £3,500. The architect was Mr. William Mackenzie, Dingwall; and the contractors were: Mason work, Messrs. Tuach and Son; carpenter, Mr. Wm. Macdonald; plasterer, Messrs. Mackay and Son; plumber, heating, and electric light, Mr. Donald Mackenzie; slater, Mr. Rod. Fraser; painter, Mr. James Mackenzie.

EALING.—The foundation stone of a new church-house, club rooms and chapel for St. Saviour's Church, has been laid. The building is in late Gothic style, and will cost about £4,000.

EBBW VALE.—The new church of St. John, Newtown, erected from the designs of Mr. G. E. Halliday, F.R.I.B.A., has been opened. The structure, which was built by the Ebbw Valley Building Company, seats 500 people, and has cost about £3,000.

EDINBURGH.—The Charlotte Chapel in West Rose Street is to be rebuilt on the present site at a cost of between £6,000 and £7,000. The new building is to provide accommodation for 1,000 persons in the main hall, 500 in the lower hall, and 250 in an upper hall. Mr. J. A. Arnott and Mr. J. Inch Morrison, of 21, York Place, are the joint architects.

FAILSWORTH.—The foundation stones of the Macedonia Congregational Church have been laid. The building will seat 500 people, and is designed in a modern treatment of Gothic, with facings of red-pressed brick, with dressings of grey terra-cotta. The total cost, inclusive of land and furniture, will be about £2,400. Messrs. Ernest Ogden and Percy C. Hoy, A.R.I.B.A., are the architects.

FAIRHAVEN, LYTHAM.—A new Wesleyan Church is being erected here at a cost of £5,250, to the designs of Mr. A. Brocklehurst, Adelphi Chambers, Brown Street, Manchester. The design is in the late decorated Gothic, the main features being the five-light traceried windows over the front double entrance doors, and massive but graceful towers. Externally, the building is being faced with Rossendale wallstone with Stancliffe white dressings, and the roof covered with Westmoreland green slates. The general contractors are Messrs. Smith Bros., Ltd., Burnley and Blackpool.

GLASGOW.—The merchants' house building has been re-opened after extensions and internal reconstruction, from the designs of Mr. J. J. Burnet, A.R.S.A., F.R.I.B.A.

GLOUCESTER.—A L.G. Board enquiry has been held relative to a proposed loan of £15,000 to the County Council for extending the Shire Hall. Plans have been prepared by Mr. R. Phillips, Assoc.M.Inst.C.E., Consulting Surveyor to the Council. Tenders have been invited for the new building, the lowest amounting to £13,857 16s. 6d.

GOUROCK.—A new school in Binnie Street for 700 scholars has been opened. Sewing and art rooms and a science laboratory are included in the accommodation, there being 12 classrooms and a large hall. Mr. Alex. Cullen, of Hamilton, was the architect, and the cost amounted to £9,295.

HANLEY.—The Town Council has accepted the tender of Mr. Godwin at £4,793 for the erection of the new Council Chamber over the Quarter Sessions Court. The plans have been prepared by the Borough Surveyor and Mr. A. Scrivener.

HARROGATE.—The new Church of St. Andrew, Starbeck, is to be commenced immediately. The cost is estimated at £6,100.

HASLINGDEN. — The new infirmary buildings are in course of erection. Provision is made for 158 beds, a maternity ward, and a nurses' home. Mr. Henry Ross is the architect. Wm. Brown and Sons, of Salford, are the masons employed, and the other contracts have been placed as follows:—Moore, Rawtenstall, joiner; Riley, Accrington, plumber; Cooper, Manchester, steelwork; Whitehead and Binns, Rawtenstall, plasterer; Holt, Haslingden, slater; Houlgrave, Accrington, painter. The heating will be done by the Brightside Engineering Co., Sheffield; the ventilating by Hargreaves, of Bury, and the warm air ventilating stoves by E. H. Shorland and Bro., of Manchester.

HEANOR.—A Baptist Sunday School is being erected here at a cost of £1,186.

HEYWOOD.—The tower of All Souls Church, which is being erected by the Vicar, the Rev. Rathbone Hartley, to the memory of his late wife, will stand about 80ft. high, and is faced with dressed stone and Yorkshire parpoints in keeping with the rest of the church.

HINDLEY. — A new Congregational Church (St. Paul's), will be commenced shortly, on the site of a former church, dating from 1815. Mr. Herbert Wade, of Blackpool, is the architect, and Mr. J. Cocker, of Walkden, the contractor.

HOVE.—For extensions at the Infectious Diseases Hospital, the Town Council has accepted the tender of Messrs. Peerless, Dennis and Co., of Eastbourne, at £5,236.

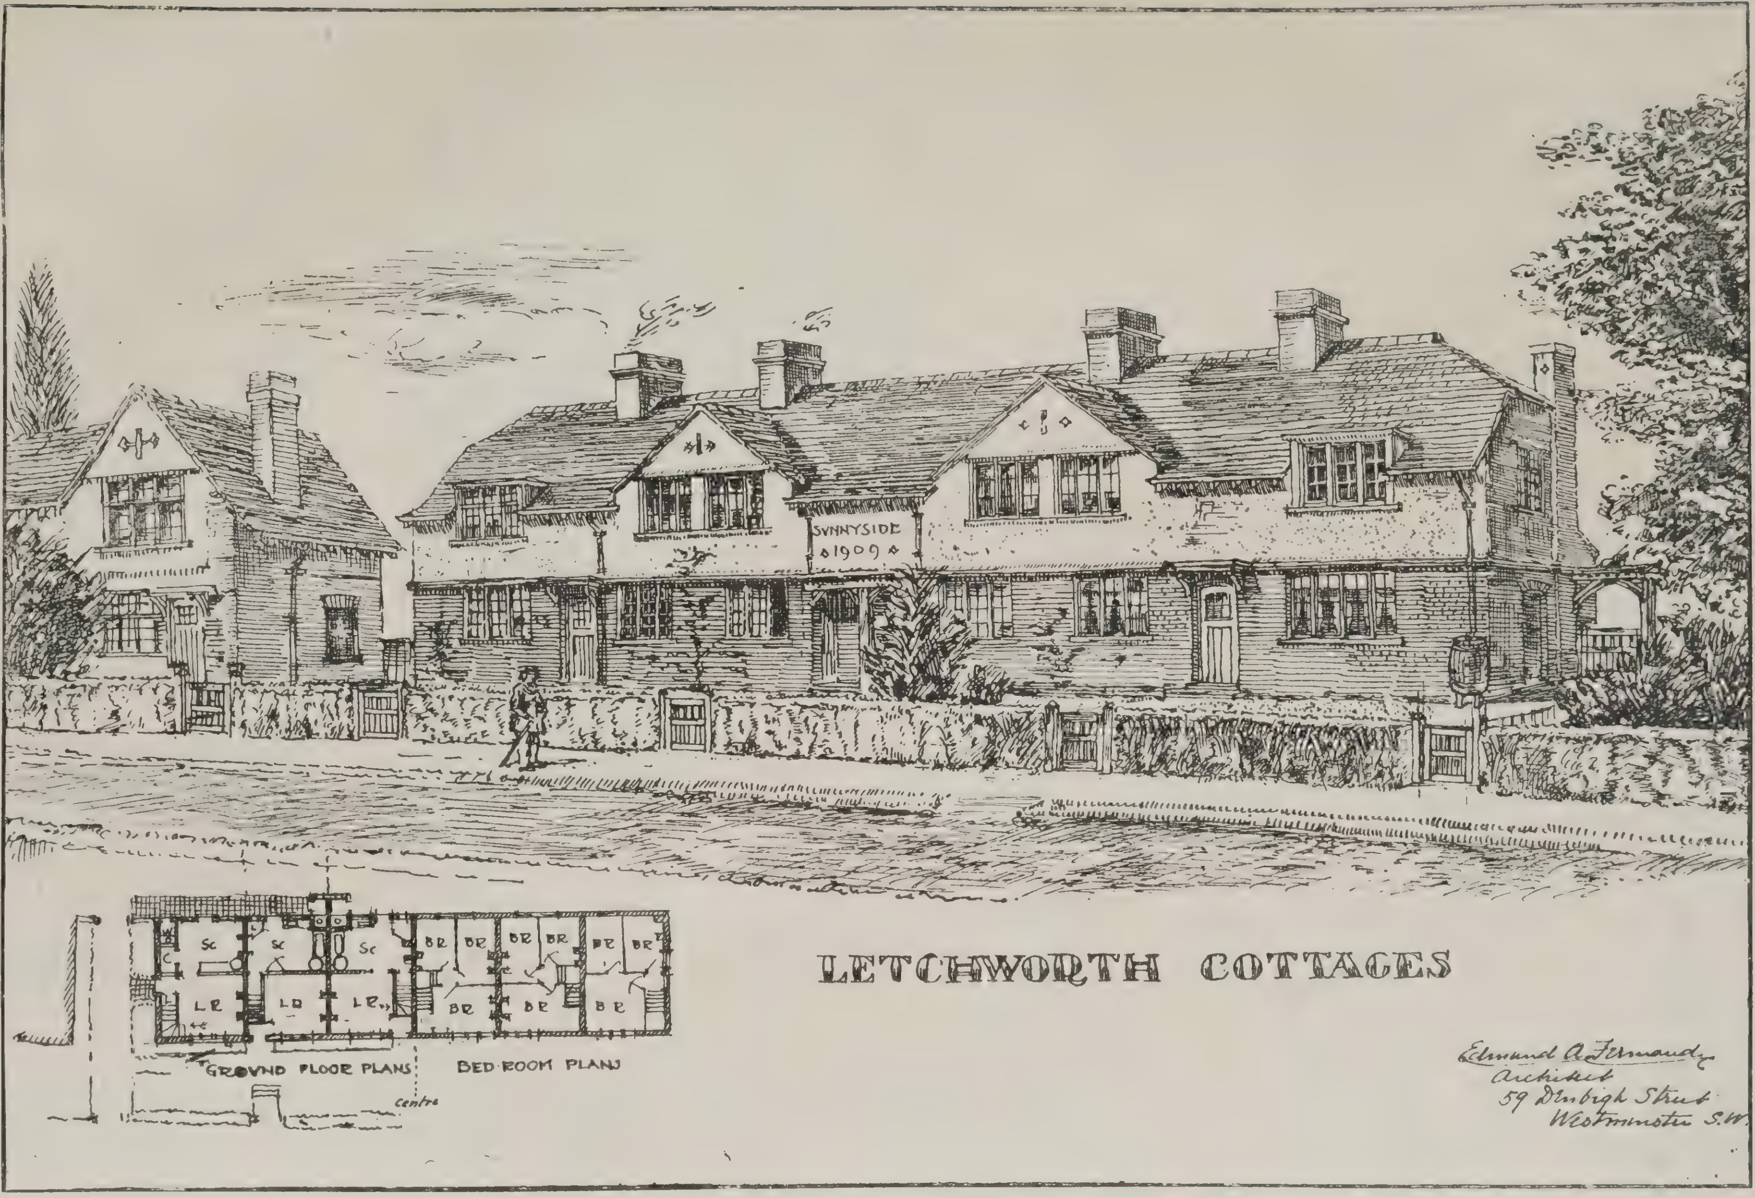
HOWRAH (INDIA).—The provision of a separate building to accommodate the office of the Superintendent of Police, the Court "hajat," the "malkhana," and the Court Inspector's office having been sanctioned, the local P.W.D. are taking steps to erect the necessary building, which will be a two-storied "pucca" structure with terraced floor and roof, over steel joists and tees. The estimated cost of the proposed building is Rs.35,600 (about £2,374).

HULL.—The new post-office is to be opened by the Postmaster-General on July 22nd. The building in Renaissance style is situated at the corner of Lowgate and Alfred Gelder Street, and has been designed by Mr. W. Pott, A.R.I.B.A., of H.M. Office of Works. Messrs. Arnold and Sons, of Doncaster, are the contractors, and the cost has been £53,000. Mr. James Atkinson, of H.M. Office of Works, supervised the work of erection.

KIRKCALDY.—A new Salvation Army Citadel has been erected here by Mr. Robert Frew, Cupar. Mr. W. Dow, of Kirkcaldy, was the architect, and the following were contractors for various works:—Mason, Messrs. Wright and Reekie; joiner, Mr. David Simpson; plumber, Mr. Jas. Blyth; plasterer, Mr. Wm. Grant; slater, Mr. Wm. Currie; glaziers, Messrs. James Haxton and Co., of Kircaldy.

LEEDS.—The new district Church of St. Hugh, Armley Lodge Road, has been erected at a cost of about £5,000.Mr. H. S. Chorley, of Leeds, was the architect.

LIVERPOOL.—The repair of the roof of the Philharmonic Hall is rapidly progressing under the supervision of Messrs. T. Mellard Reade and Son, architects to the society, in consultation with Mr. Hall Blyth, M.Inst.C.E., of Edinbugh. The contractors are Messrs. Jones and Son, Pleasant Street, Liverpool, and the steelwork is being supplied by Messrs. Redpath, Brown, and Co., of Trafford Park, Manchester. One of the



COTTAGES, LETCHWORTH. EDWARD A. FERMAUD, ARCHITECT.

This design, placed first by the Committee of Assessors at the last Letchworth Cottage Exhibition, is for a block of six cottages with frontages of 16 feet. Two serviceable rooms are provided on the ground floor in preference to the usual parlour, kitchen and projecting scullery, which in many cases interferes with light and prospect. The walls are faced with red bricks with cement roughcast to upper part. The roof is tiled. The living rooms have wood block floors (on 6 inch cement concrete) in order to avoid vermin. The first floor is pugged and plastered between joists which are left exposed and stained. The partitions on upper floor are solid and finish 3ins. thick. Mr. E. A. Fermaud of 59, Denbigh Street, Westminster, is the architect.

great difficulties was to design the new superstructure so that it could be erected without exposing the interior decorations of the hall to possible damage from the weather. The steel frame superstructure, weighing some 50 tons, is being built over the old roof four feet above its ultimate level, and when all is ready the old roof will be cut open, and the whole of the new structure lowered by hydraulic jacks on to its beds on the four-brick piers at each corner of the hall, and the ceiling secured. The new roof, which is to be covered with copper for lightness, will then be completed and all covered in. From the exterior the new roof will appear as two large pediments or gables above and at either end of the old roof; and along the centre, for a width of 12ft. on either side of the ridge, the new roof will run from gable to gable at a height of about eight feet above the old roof. During the operations now in progress the whole roof and ceiling are being supported temporarily by 14 wood skeleton towers, 70ft. high from the floor to the roof, and those who only know the hall during the concert season would doubtless be surprised to see the avenues of timbering which now occupy the auditorium. It is expected that the work will be completed early in September.

LONDON.—The Marylebone Borough Council have accepted the tender of Mr. B. E. Nightingale, of Albert Works, Lambeth, at £13,560, for the erection of the new borough depot buildings.

LONDONDERRY.—The corporation have had plans and a specification prepared by Mr. W. E. Pinkerton, for rebuilding the Guildhall, which was burnt out some time ago. These plans and the specification have been submitted to the City Surveyor and to the Town Clerk, who are reported to have stated that they could not advise the corporation to place them before the quantity surveyor, as they were not in the requisite form for the lump sum contract, which the corporation desired. After a very protracted discussion, during which Mr. Pinkerton refuted the suggestion that the plans and specifications were not in a fit state to go before the quantity surveyor, the corporation decided, under their agreement with Mr. Pinkerton, to take them over and pay him the sum of £300 for his services. Mr. Pinkerton refused to accept the sum as a settlement of his claim; but the Mayor intimated that the Corporation would consider any claim for extra work.

LONGTON.—The new post-office in Chancery Lane has been formally opened. The cost has been £3,500, and the contractors were Messrs. Tompkinson and Battelley, of Longton.

MADRAS (INDIA).—The Madras Council is considering designs for the new Council Chamber and offices to be erected shortly on the site of the Old Banqueting Hall behind the Secretariat Buildings in Fort St. George. The cost is estimated at two lakhs of rupees (about £13,400).

MANSELTON.—A new English Baptist Chapel, to seat 650, is being erected in late Gothic style, of local stone, with blue Pennant stone facings and Bath stone dressings. Mr. W. Beddoe Rees, Cardiff, is the architect, and Messrs. Turner and Sons, Cardiff, are the builders. The cost will be about £3,000.

MOUNTAIN ASH.—The nave and aisles of the new Church of St. John the Baptist, Miskin, have been completed, and the building has been consecrated for worship. The present accommodation is for 485 persons; but when the chancel, vestries, and parish rooms have been added, there will be a total accommodation of 515 sittings. The building is faced with grey pennant stone with the traceries of St. Aldhelm stone, and the roofs are covered with green Bangor slates. Mr. E. M. Bruce Vaughan, Cardiff, was the architect, and Messrs. E. Turner and Sons, of Cardiff, were the contractors. The cost has been £3,500.

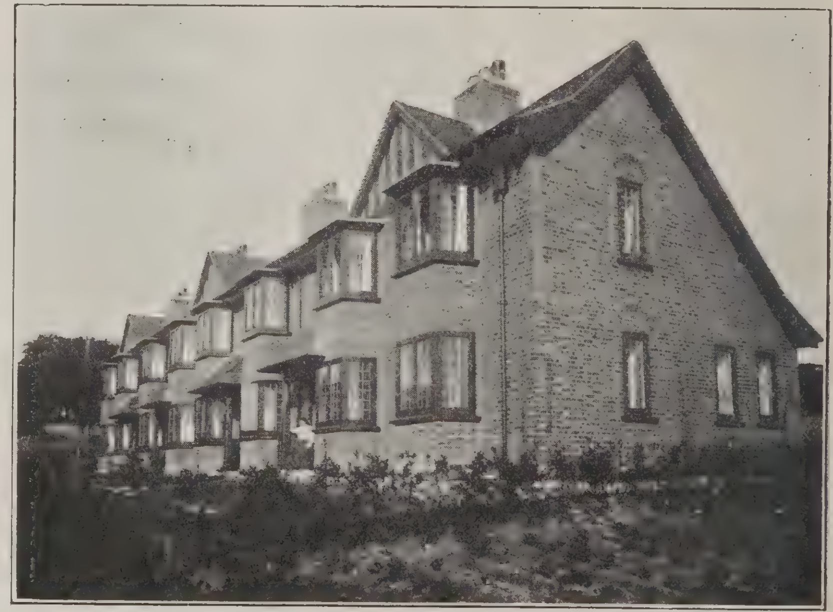
NEWPORT (MON.).—The foundation stone of the Technical Institute at the junction of Clarence Place and Rodney Street, has been laid. The building, with equipment, will cost about £40,000, is to be finished by July, 1910, and has been designed by Mr. C. F. Ward, A.R.I.B.A., the borough architect. Mr. W. E. Blake, of Plymouth, is the contractor.

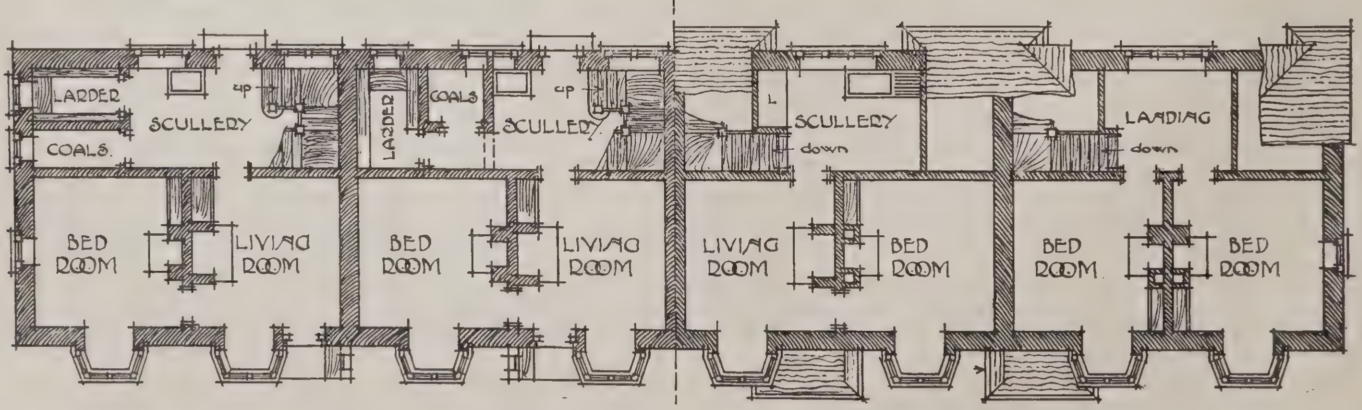
NORTHAMPTON.—The contract for the rebuilding of Messrs. T. C. Mann and Sons' factory, which was burnt down at the beginning of the year, has been secured by Messrs. Sharp and Robinson, of Earls Barton, and operations are now in progress.

ST. PAUL'S BRIDGE.

After long deliberation, the Bridge House Estates Committee of the Corporation of the City of London have decided to recommend a drastic improvement of the means of communication between north and south London via the City. The committee, after considering the matter for four years, have decided to recommend that, while the gradient of Southwark Bridge shall be improved, a new bridge shall be provided between it and Blackfriars Bridge, and shall be continued by a viaduct to Cannon Street, near the east end of St. Paul's Cathedral. The estimated cost of the two schemes is nearly £1,878,000.

In their report, which will be submitted to the Court of Common Council at its next meeting, the committee point out that additional means for meeting the requirements of cross-river traffic within the City are urgently needed. During the busy hours of the day, when easy transit is most required, the bridges serving the City (with the exception of Southwark Bridge) are greatly congested, and the need of an additional traffic artery is obvious. Southwark Bridge would suggest itself as being, if reconstructed, the means by which relief might be obtained. The construction of an approach wide enough to render a new Southwark Bridge a successful undertaking would, however, involve the acquisition of property so costly as to make the undertaking almost prohibitive. To construct a short approach, ending in Queen Victoria Street or Cannon Street, would only have the effect of creating congestion in an area the traffic of which is already difficult to deal with, owing to the two lines of east and west traffic at the Man-





HOUSE OF REST, WHEATLEY, OXON. S. STALLARD, ARCHITECT.

These cottage homes are built of red brick with tiled roofs, and the exterior woodwork is stained brown.

sion House Station diverging and crossing each other, and meeting others coming in an opposite direction.

Realising, however, the necessity of providing improved means of communication, the committee instructed Mr. Basil Mott, C.E., to report (1) on the best method of reconstructing Southwark Bridge, (2) on the question of constructing a new bridge between Southwark Bridge and Blackfriars Bridge, and (3) on the best means of improving the present gradients of Southwark Bridge. Mr. Mott submitted plans showing three different methods of reconstructing Southwark Bridge:—(*a*) for a new bridge with a new northern approach by a viaduct over Thames Street to Queen Victoria Street, at a cost of £878,325, or if widened to 80ft., £966,574; (*b*) for a new bridge on its present site, with a new approach to Queen Victoria Street as in scheme (*a*) at a cost of £876,194, or if widened to 80ft., £964,443; and (*c*) for reconstructing the present bridge, with a viaduct over Thames Street to Cannon Street, with two new approaches from Thames Street to the bridge, at a cost of £1,086,225.

With regard to the construction of a new bridge, Mr. Mott's report suggested the erection of a new bridge, commencing at the junction of Southwark Street and Southwark Bridge Road, ascending in a north-westerly direction, crossing the river in three spans, and then being continued by a viaduct over Upper Thames Street and Queen-Victoria Street, terminating at Cannon Street, near St. Paul's Cathedral. The construction of such a bridge would have the effect of creating a new north and south thoroughfare. The bridge, which is provisionally indicated by the name of "St. Paul's Bridge," is shown in the plan as widened to 80ft. to accommodate tramways from its southern end to its termination in Cannon Street. An improvement which might be carried out in the future is the acquisition of certain property north of Cannon Street and to the east of the Cathedral, in order to carry the thoroughfare to St. Martin's-le-Grand.

In this scheme the tramways, on reaching the north side, would dip into a subway and ascend in Aldersgate Street, thus avoiding interference with the surface traffic in the City. The estimated net cost of constructing the suggested new bridge 80ft. wide is £1,646,983.

In all plans for rebuilding Southwark Bridge, the committee state the subject of the northern approach will be the vital point; and such an approach cannot be made without absorbing a large area of most valuable property, the cost of which makes it improbable that it will ever be attempted. It therefore appeared to them useless to proceed with the proposals referred to; but it was continually being urged upon them that the heavy traffic in Thames Street should be afforded an improved outlet to the south side of the river.

They therefore had prepared a plan showing an improvement of Southwark Bridge by lowering the crown of the arches and reducing the gradient to 1 in 33. The estimated cost of this proposal, including compensations, is £231,000, and Thames Street and the streets communicating with it are not interfered with.

As to the proposed new bridge, "the possibility of obtaining a new north and south thoroughfare capable of accommodating tramways without interference with the surface traffic of the City is a highly desirable and attractive one." In the opinion of the committee, therefore, the proposals that should be adopted are—(*a*) the new bridge at an estimated cost of £1,646,983; and (*b*) the improvement of the gradients of Southwark Bridge at an estimated cost of £231,000.

The work would be carried out without cost to the ratepayers, from the Bridge House Estates funds, which, it will be within the recollection of readers, supplied the money for erecting the Tower Bridge.

Fire Prevention Notes.

A Homely Little Homily. A useful little homily on fire prevention, appearing in a popular medical journal, insists on such obvious truisms as to raise a temporary suspicion that they were intended to be addressed to the nursery. Thus, we are told that lamps and candles should not be set where draperies can be blown to them, that ashes should be taken up in a fireproof vessel, and that care should be exercised in the use of paraffin. Unfortunately, the adults of the community show in nothing more clearly than in their general recklessness with regard to fire that they are "but little children of a larger growth," and that therefore this very elementary advice is by no means superfluous. Nor can it be said that the equally rudimentary remarks on building are unnecessary. "Far too little attention to safety from fire," remarks our homilist, "is paid in building. Besides the use of inflammable materials, there are often inaccessible little cubby-holes and attics; chimneys or pipe-holes in unsafe places; the water supply in the most unhandy position; and no provision made for reaching the roof." This is only too true; but the writer sets up a somewhat dubious doctrine when, after delivering himself of the further truism that "a little forethough in planning a house would often make it safer," he suggests that "the money sometimes spent in needless ornamentation would pay for the most important parts being of fireproof materials, insuring almost entire safety." It is true that there is here much virtue in the word "needless"; but the suggestion of any sort of rivalry between fire-prevention and æsthetics is also needless, and might tend to the utter discouragement of the babes and sucklings, to whom the writer is endeavouring to teach the ABC of the subject.

Pioneer Efforts in Fireproofing. For the first strenuous attempts at rendering buildings fireproof it is natural to turn to American records. As long ago as 1856, Mr. Peterson, architect, used, with this object, hand-made hollow tiles in the first floor of the Cooper Institute, New York. Later, the Fireproof Building Company, of New York, were endeavouring to protect ironwork from the effects of fire by coating it with a composition of plaster of Paris and a French cement known as lime of Tiel, and they used hollow blocks that were made in accordance with the system invented by Garcin in 1867. A hollow-tile floor, invented by George H. Johnson, was used in the New York Post Office about 1872, and in the same year that gentleman rebuilt the Equitable Building, which had been destroyed in the great Chicago fire, with hard-burned hollow clay blocks, a system that he also applied in a building for the Singer Sewing Machine Company at St. Louis. Flat arches of burned clay were used in the halls of the New York Coal and Iron Exchange, which was built about 1876 by the Fireproof Building Company from the plans of Mr. Richard M. Hunt, who later adopted a similar specification for the floors of the "Tribune" building. In 1875 and 1876, Mr. Thaddeus Hyatt, an American, made exhaustive experiments with reinforced concrete in England, and chronicled the results in a book that was circulated privately in 1877. In 1876, Mr. William L. Ward, of Portchester, commissioned Mr. Robert Mook, architect, to build a large house, in which the walls, floors, roof, partitions, and porches, are of reinforced concrete, and this, so far as is known, is the first instance of the structural use of reinforced concrete in America. Other early examples of fireproof construction in America are as follows:—In 1875 the first cast-iron columns fire-proofed with burned clay were used in the Chicago Club, porous terra-cotta blocks being fastened to the column with screws. In 1878 the floor arches of Cook County Court House at Chicago were built with flat hollow tiles. In 1880 the Chicago City Hall was the first large public building of which the entire interior was constructed with hard-burned hollow tile, with hollow-tile fireproofing for all columns and girders, and a hollow brick-tile roof. In 1879 parts of the Chamber of Commerce at Milwaukee were fireproofed with porous terra-cotta, of which blocks were screwed to the iron columns, while the ceilings were covered with 2in. tiles screwed to the floor-joists. Similar construction was adopted in the same year with respect to the 500 columns supporting a large store built by Mr. Ferry, at Detroit. Another building, erected a few years later—the Grannis Building, Chicago—was burnt out, and when the columns, which had fallen in the general wreckage, were examined, it was found that the fireproofing was still attached to them, uninjured. The first office building of fireproof construction throughout, in the modern style, was the Montauk, in Chicago, which was erected in 1881-2, and is noteworthy as being the first in which concrete and iron grille foundations were used. It successfully withstood a severe fire in an adjacent building. It was taken down in 1907. The first building in which the bottoms of the iron beams were protected by burned-clay tiles was the Mutual Life Insurance Building in New York City; the contractor having patented a method by which the soffit tiles could be held in place. This building was erected in 1883-4.

Fire Prevention in Germany. The special commission of the executive officers of the British Fire Prevention Committee, which visited Berlin and Hamburg, have returned to London. The commission comprised half-a-dozen prominent officials of the committee. The questions examined by the commission on the journey related chiefly to the construction of large drapery stores, warehouses, theatres, schools, and hospitals. The commission also viewed a number of petroleum stores, scenes of fires, and they had an opportunity of inspecting a number of new fire stations and of witnessing demonstrations with modern fire appliances. On their journey outwards they visited Hanover, and some of the members of the commission also visited Kiel. At Berlin the occasion of the visit was taken by the chief officer of the Royal Police Fire Brigade to arrange a special display of the working of his brigade. The arrangements for the journey having been carefully prepared in advance, and the authorities having put all possible facilities at the disposal of the commission, a mass of useful data was obtained, and it is intended to publish the information thus obtained.

Fire Prevention a Duty. An extensive fire at Bromley, in Kent, last month, emphasises the fact that there is an enormous field for missionary work with respect to fire prevention. Bromley, which but a few years ago was little more than a village, has grown rapidly to the dimensions of an authentic and unquestionable town; and yet apparently it is being built up without very much regard for modern fireproofing methods. But, leaving Bromley out of the question, it is certain that, in spite of all precept and example, there is still too much trusting to luck in the construction not only of dwellings but of business premises. Immediate interest—the saving of a few pounds on the contract—seems to outweigh any consideration of the terrible risks that are involved in neglect of the available means of fire prevention. It is for this reason that some day—probably as the result of some disaster of appalling magnitude—legislation will compel proper precautions against the outbreak of fire, and more particularly against its extension. It would seem to be feasible that the occupant of a house has a moral right to demand protection against the destruction of his property and the risk to his life that may arise from the failure of his neighbours to adopt known means of confining an outbreak of fire to the apartment in which it originates.

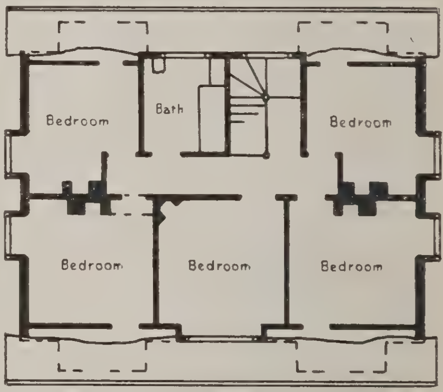
The Fastening of Fire Doors. A glance over the photographs of several of the fire door tests that have been carried out by the B.F.P.C. suggests an interesting point that should be of some moment to the manufacturers of doors other than roller shutter doors, and also to the architects who contemplate using them. That point is concerned with the arrangements for securing the door. In the majority of the tests, however well the door stood the tests, a tendency was shown to buckle inwards at the top and bottom corners of the doors, allowing the flame to pass over, under, or round them. In later tests this was obviated by securing the door with additional bolts at the top or bottom of the opening side, and in one case the door was secured by three bolts on the opening side, and on the hinge side by the two hinges and, half-way down, by a lug shutting into a slot when the door was closed. This arrangement kept the door tightly secured to the frame and prevented the door warping or buckling or allowing any flame to pass. The point is worthy of attention. But as a corollary, it is also necessary to arrange that the three bolts on the opening side can be shot or drawn simultaneously. In case of fire, every moment is of importance, and in the general excitement, and, perhaps panic, it is not well to leave too much for the human element to achieve in the face of danger.

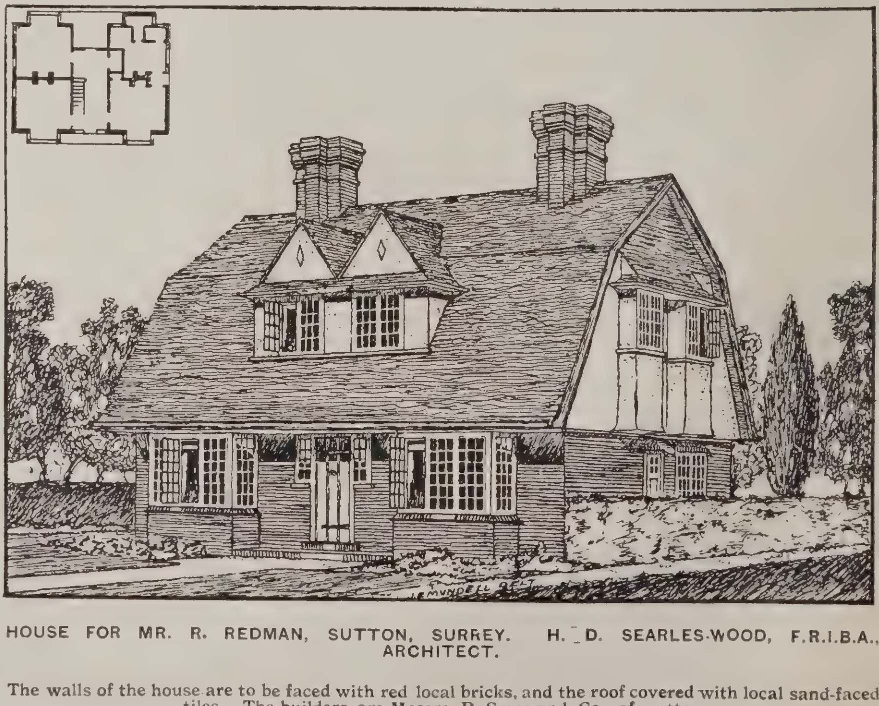
Fire Tests. During the present month additional tests with roller shutter doors will be undertaken. A further series of tests with fire extinguishers has been arranged. Of tests undertaken during the past month, there were tests with three doors, one of which was a 3-ply wood, asbestos protected "armoured" door to a 7ft. opening. Another was a similar door, but 2-ply, into an opening of about 3ft. The third was with an iron door. The British Fire Prevention Committee will in due course issue reports upon these tests.

Fireproof Construction and the By-laws. The Committee of the House of Commons, of which Mr. Mooney is chairman, have given decision on Part V. of the London County Council (General Powers) Bill, under which it is proposed to amend the London Building Acts, 1904 to 1908, with special reference to buildings of iron and steel skeleton construction, and to make regulations as to the use of reinforced concrete. Clause 30, sub-clause (33), provides that any person dissatisfied with any requirement or decision of the district surveyor in regard to metal skeleton framework construction may appeal to the County Council, whose decision is to be final. The Tribunal of Appeal established under the Act of 1894, had been substituted for the County Council, but the committee directed that the appeal should be to a police-court magistrate. Sub-clause (34) provides that, in order to facilitate the erection of buildings of metal skeleton framework, the Council may modify or waive any of the requirements of Clause 30 "upon any subject to such terms and conditions as they may think fit, and any person failing to comply with any such term or condition shall be liable to a penalty, to be recoverable in a summary manner, not exceeding £20, and to a daily penalty not exceeding the like amount." The committee decided that there should be, in regard to this provision, an appeal to the Tribunal of Appeal. They also directed that Clause 33 (increased fee to district surveyor in certain cases) should be altered so as to make clear the exact basis on which the fees of the district surveyor were to be calculated in the case of the alteration of an existing building of metal skeleton framework construction. The committee found the preamble of the Bill proved.

ROMAN KITCHENS AND ROMAN COOKERY.

Co-existent with the advanced state of civilisation and luxury closely identified with the establishment of the ancient Roman empire, was the cult of cookery by the gluttonous old time denizens of the eternal city. Doubtless much of the culinary skill of the Romans was inherited from the Greeks who, in their turn, acquired it from other nations, perhaps more particularly from the Egyptians and Lydians, whose cooks were in great request, when Athens reigned supreme over Hellenic national life. But whatever degree of excellence in the refinements of civilisation may have been obtained by their illustrious predecessors, it was reserved to the Roman conquerors of the world to raise gastronomy to the level of a fine art. Thus the "culina" or kitchen, necessarily became one of the most important of the many stately apartments of the Roman mansion. In addition to the periodical banquets provided for the delectation of their personal friends (which led the rich citizens of Rome to sweep land and sea to furnish food for the gastronomical orgies at which they were accustomed to pass whole days or nights), it was usual for the wealthy City parvenu to distribute, day by day, an immense amount of food to his humble dependents ("clientes") and it thus became necessary for him to pay special attention to the culinary department of his household. Many of the kitchens attached to Roman houses presented the appearance of large vaulted halls, wooden ceilings being eschewed in order to lessen the possibility of accidental fire, and an ancient inscription, discovered many years ago at Palestrina, instances a kitchen no less than 148ft. in length, but this particular *Culina* does not appear to have been of more than average size. The Roman kitchen was profusely decorated, its walls being elaborately painted, often with a representation of the *Fornacalia* (a festival in honour of *Fornax*, the goddess of furnaces), varied by paintings of fish, poultry, and game. One of the most noticeable features of the room was its paving, usually consisting of a fine black composition possessing the extremely useful property of rapidly absorbing water, and thus the floor of the Roman kitchen always remained dry. Over the hearth (*caminus*) upon which the fire for cooking was laid, there was a large archway (*fornix*) constructed to afford a ready vent for the smoke. Subsidiary offices, planned for use in connexion with the *Culina*, were the *Olearium*, for storing oil, the *Horreum*, a storehouse for winter provisions, the *Pistrinum* or bakehouse, which was separated from the main building as a precaution against the spread of fire, the granaries and the wine cellars. The latter were often of enormous size. It is said that the cellars of Hortensius, the orator, contained no less than 10,000 casks of Arvisian wine. The wine cellars and granaries were usually placed upon the north side of the house to protect their contents from the damage which might otherwise occur through exposure to the heat of the sun, and refinement was sometimes carried to the remarkable extent of perfuming the cellars for the purpose of giving the wine a superior flavour. A branch of cookery on which the Roman *chefs* especially prided themselves was that of making artificial birds and fishes of such delicious flavour that their exquisite taste is said to have excelled the reality. Their skill in the art of making bread, of which Pliny mentions four kinds, was also very noticeable.





HOUSE FOR MR. R. REDMAN, SUTTON, SURREY. H. D. SEARLES-WOOD, F.R.I.B.A., ARCHITECT.

The walls of the house are to be faced with red local bricks, and the roof covered with local sand-faced tiles. The builders are Messrs. R. Smee and Co., of Sutton.

THE CONCRETE INSTITUTE.

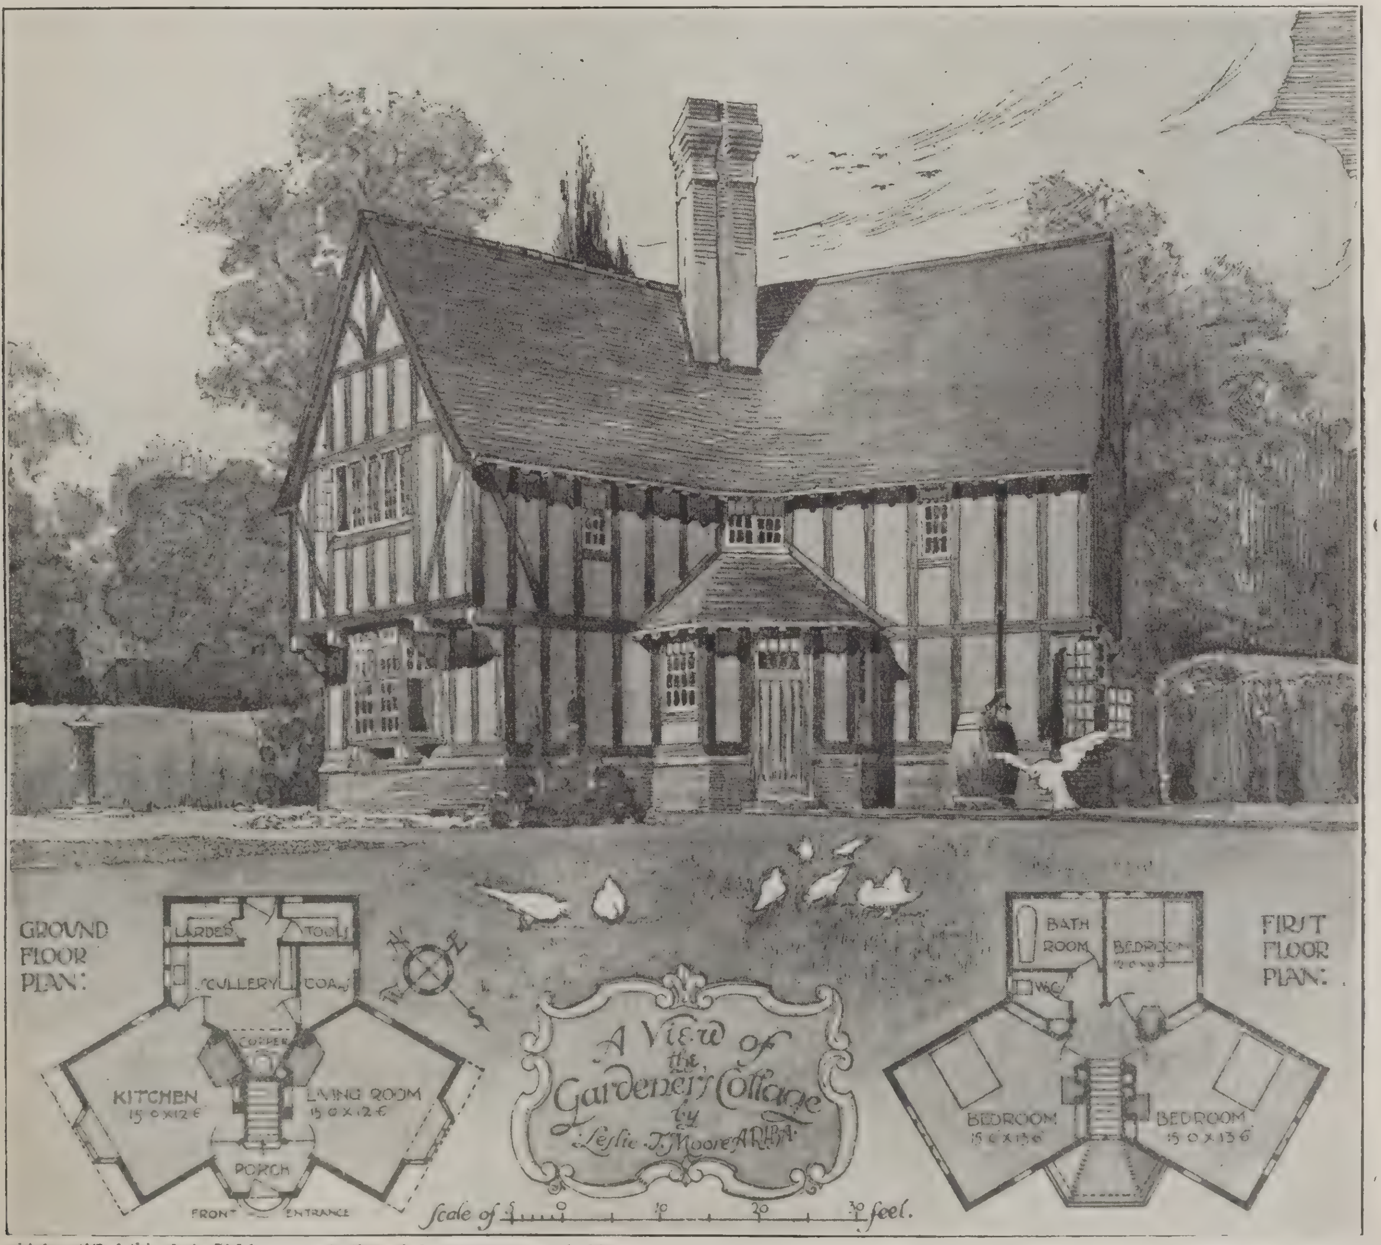
The Setting of Portland Cement.

A general meeting of the members of the Concrete Institute was held on Thursday evening, June 17th, at the Royal United Service Institution, Whitehall, S.W., for the purpose of resuming the debate, adjourned from the previous meeting, upon a paper read by Mr. H. K. G. Bamber, F.C.S., on the setting of Portland cement, and the methods adopted for regulating same. Mr. F. E. Wentworth-Shields, M.I.C.E., presided, and a somewhat protracted, but interesting, discussion took place, among those present being: Messrs. Bamber, E. P. Wells, J.P. (hon. treasurer), H. Kempton Dyson (secretary), Blount, W. H. Reid, J. W. Plaistor, A. O. Trechmann, Wm. Gilbert, G. B. Blyth, J. F. Fenwick, J. W. Davis, etc.

The Chairman said that a suggestion was made at the previous meeting that M. Le Chatelier, the author of the famous cement test which bore his name, should be invited to attend that evening and take part in the discussion. Unfortunately, he had not been able to come, but he had written from Paris to Mr. Bamber, who had made a translation of the letter.

Mr. Bamber then read the translation of M. Le Chatelier's letter, which dealt with the questions of tricalcic silicate, quickness of setting, hydration of cement by steam, and tests of the unchangeability of volume and heat. Mr. Bamber remarked that he much regretted M. Le Chatelier's inability to be present, but he wished to express their indebtedness to that gentleman for the trouble he had taken in sending a few notes on the subject before them. He was glad to accept the assurance of M. Le Chatelier that the many theoretical difficulties of the supposed complex chemical combinations that might be formed had not the importance usually attributed to them, and further, that they had nothing to do with the practical application of cement. He thought, therefore, that the manufacturer might well leave these questions to the specialists, and that the consumer need not worry himself about the chemical side of the question, but should confine himself to seeing that his cement conformed to the specification.

Mr. Walter Reid, F.I.C., said that with regard to Mr. Bamber's observation as to lime being present in cement in a different form from that in which they were accustomed to see lime, and in which it slaked and expanded considerably in volume, he thought that was a remark of the greatest importance. In many cases they had got no lime, and when they put the product in water it did not slake at all, yet after a time the water in which it was put became alkaline, and caked up lime. There could be no doubt whatever that at the temperature at which cement was clinkered, lime did exist in a different state from what it did in ordinary lime, and was one of the reasons why the search after free lime had given so much trouble to different investigators. In practice it had been found that that form of lime could be produced in another way in connection with limelights. Lime for limelights were made of caustic lime highly compressed and saturated with nitrate of lime, and calcined at a high temperature. The process was repeated, and they got a substance, almost metallic in its hardness, which would stand the atmosphere for a very long time indeed. He had made many thousands of tons of cement in the old way, with the old kilns, but his experience led him to the conclusion that fuel ash had very little to do with the setting of the whole charge of the kiln. Over and over again he had picked out pieces of clinker from a kiln and ground them separately, and found that they more or less agreed with the setting of the bulk of the charge from the same kiln. To his mind, it was quite impossible that the small percentage of ash which was contained in the fuel could have any appreciable effect on the



The chief motif of this design is the concentration of flues to one central chimney stack. The "Y" form of plant adapts itself admirably in this respect, also to simplicity in roofing. The rooms are a pleasing shape, all having fireplaces suitably placed. Externally the cottage forms a picturesque whole; gaining all the advantages of aspect. The general framing, standing on a brick base, is to be of local hewn oak, left from the adze, filled in between with brick nogging, the panels being finished in plaster. The tiling of the roof is to be eased round the internal (obtuse) angles, following the old methods. The roof could equally well be thatched where the material is available. Mr. Leslie T. Moore, of 3, Raymond Buildings, Grays Inn, is the Architecet.

time of setting of the cement, and he definitely stated, as the result of his experience, that the time of setting was dependent on the composition of the material as it was put into the kiln, and only in a very small degree indeed upon the small fraction of ash that might be derived from the fuel. With regard to the action of carbonic anhydrite on cement, he did not think it did so act in practice; it could only be when it was combined with water that it would act. With regard to the actual materials that were present in cement, he thought one ought to bear in mind the fact that chemical substances nearly related to each other almost always dissolved each other, and he thought the hope of isolating definite compounds from the clinker itself was altogether illusory, because there was no doubt that the silicates formed in the clinker, and the aluminates were so closely allied chemically that they acted as mutual solvents. They were almost driven to the method of experimenting which Mr. Bamber had himself carried out, viz., the formation of different silicates, and the testing of them separately. With regard to carbonate of lime being inert in the mass, Mr. Bamber treated it as if it were absolutely inert, but he thought there was no question at all that carbonate of lime was an important ingredient in mortar, and that it was not absolutely inert. The other day he examined some mortar which was probably 4,000 years old, and then there was the mortar from Pompeii, which he had also examined, and that contained as an important ingredient powdered marble. The lime that was used as a plaster, whether with sand or alone, would certainly not have stood like those ancient mortars in which, as Vitruvius told them, the mortar was made up with powdered carbonate of lime in a hard form. Therefore, he did not think that if cement had been weathered they should assume that, because a certain portion of the mass became hydrated, it was inert. With regard to the question of reducing or lengthening the time of setting, some interesting experiments were made a number of years ago with regard to the action of moisture in lengthening the time of setting. They were first carried out, he thought, on a large scale in Germany in the ring kiln, where they used to sprinkle water on the clinker before it was cold, and they found a material advantage in doing that, the cement setting more slowly, and altogether it was considered a great commercial advantage, and was indeed at that time kept a secret. But, curiously, he had previously done it himself at Rugby in cases where the stone was not so intimately mixed as it might be, and there was almost visible free lime in the clinker. The ingenious process that had been devised by Mr. Bamber for carrying out the partial hydration in a measured way was likely to get over any difficulty that might still remain in that particular operation, and he congratulated Mr. Bamber on having thought out so accurately a method of carrying out the operation on a manufacturing scale.

Mr. Wm. Gilbert, M.I.C.E., said he would like to ask if the setting time of cement was better controlled by preserving the high temperature of 180 degrees Fahr. than the more usual temperature of 140 degrees. With regard to the Le Chatelier test, it appeared to be a weak point in it that no measurement of expansion was commenced until the cement had been immersed in water for 24 hours.

Mr. Trechmann said he thought that the rotary kiln was rapidly developing, but he did not think that Mr. Bamber had entirely made out a case against the fixed kiln. As to the quantity of fuel used in the competing processes, some types of fixed kilns consumed over 33 per cent. less than the best handled rotary kilns.

Mr. J. B. Blyth said he believed the rotary kiln would very shortly take a second place. He would not say that the cement manufacturers were sick of rotaries, but they were so enamoured of something else that they had given an order for eight brace on spec. With regard to the setting time, he mentioned some cement with which he had got a quicker setting time in a damp carriage house at his works than in a dry sample room. He thought the different results which they now obtained in the setting time were due to the fine grinding, which made some peculiar difference that was not shown by chemical analysis, and which did not obtain in the good, old coarse-ground days. He suggested that if users wanted to "slow" their cement it would be better to add 4 per cent. of water when they gauged up the cement than to leave the manufacturer to put it in some time previously. Personally, he was strongly opposed to the Le Chatelier test, which he thought was most misleading. With regard to cheap cement, he thought the most excellent thing that all users of cement could do was to eliminate the bottom tender of all.

Mr. J. W. Plaister said he had a strong prejudice in favour of steam aeration of cement, but he was convinced that with certain classes of clinker nothing could beat the cooling of it by exposure to the air, more especially for getting a good initial set. He would like to mention, however, that he had seen cement put into extremely important work which had been absolutely ruined by the suicidal mania for over-aeration.

Mr. J. W. Davis remarked that he had found that well-burnt intermittent kiln clinker had an almost instantaneous set. He had yet to learn that anybody could produce clinker from rotary kilns, made with chalk and clay, that was anything but quick setting when it was first ground, unless it was treated by some method for the purpose of retarding the initial setting time.

Mr. G. F. Fenwick having also spoken,

Mr. Bamber replied to the discussion both at that meeting and at the previous gathering. He agreed, he said, that the National Physical Laboratory might well take up the question of the composition of cement and thoroughly investigate it. He claimed that in some form or other the system of hydration of cement was being carried out at every works in the United Kingdom. He did not state that fuel ash had any very great effect on the setting time of cement, but he thought it might possibly have some effect in slightly retarding the setting time. As to carbonate of lime not being an inert substance, he had learned that for the first time. With regard to the temperature for the setting time being kept high, the effect was always greater and more rapid if they did it at a high temperature. It enabled them to produce a cement straight from the tube mill without aeration of any sort, which, when tested by the Le Chatelier test did not expand even the 10 millimetres referred to in the British Standard specification, and it was common to get cement tested within an hour of leaving the mill expanding only 1 millimetre. Possibly half the cement manufactured in this country was manufactured by the rotary process, and he thought the possibility of that proportion being increased was near at hand.

A Kansas City firm has offered Prof. Duncan $1,500 a year for two years to be awarded to some student to spend his time hunting for more uses for Portland cement. This provision is of unusual interest to the people of Kansas, as the cement industry promises to be one of the large interests of the State, and every new practical use discovered for the product will help the industry greatly. The chemist who secures this scholarship is to spend his time partly in the university laboratories, and partly in visiting the various cement mills in the State. He will conduct all kinds of experiments, and Prof. Duncan feels confident that he will be able to find new uses for cement. In all the leading universities of America, as well as at State and Government experiment stations, cement is receiving much consideration from both chemical and engineering standpoints. No other material is receiving equal attention. The explanation is that cement is fast becoming the most useful structural material of the age.

Federation News.

BARNSLEY ASSOCIATION.

Secretary: J. Denton.

At the monthly meeting of the Barnsley Federation of Building Trade Employers, held the the King's Head Hotel, Barnsley, on June 9th, Coun. G. Haigh (president), who occupied the chair, was supported by seventeen members. Four new members were unanimously elected.

The report of the last Yorkshire meeting was submitted by Mr. E. Broley. A small committee was appointed to make arrangements for the forthcoming annual outing, when there is to be a cricket match, "Barnsley Master Builders" versus "Rest of Federation."

A short report of the Local Conciliation Board annual meeting was submitted by Mr. C. D. Potter, who remarked upon the good feelings existing between masters and men, and the very light duties of the Conciliation Board. He had nothing of importance to report.

The president (Councillor G. Haigh), submitted a short account of the Barnsley Master Builders' tour in Ireland, describing in detail the beauties and the grand scenery of the North of Ireland. Mr. P. Dalby corroborated.

Mr. C. D. Potter introduced a suggestion, which he threw open for debate, for curtailing the various holidays of the year, and having one full week in August. Mr. F. Goodyear was in sympathy with this suggestion, but was unable to see how the minor holidays could be curtailed. Mr. E. Broley and the president suggested that the matter should be discussed at the next Conciliation Board meeting, in order that the feelings of the men could be ascertained. Mr. T. Lindley did not think it would be wise to interfere with the other holidays, and thought it would be very difficult to get a universal week's holiday. He cited the unsuccessful efforts in this direction lately made in Sheffield. Mr. C. D. Potter, in reply, admitted the difficulties, but was of opinion that they could be easily surmounted. Mr. J. Smith asked whether this question had not been previously discussed and shelved at a town's meeting. He foresaw great difficulties. Mr. H. Ashworth remarked that the building trades could manage the week's holiday themselves. Councillor W. G. England, J.P., agreed that a full week's holiday during Barnsley feast week was very desirable. Mr. C. D. Potter, in a final reply, contended that the holidays could be consolidated, and that the tradesmen connected with the building and allied trades would welcome the suggested week's holiday. Ultimately it was resolved, on the motion of Councillor W. G. England, J.P., that the matter be thoroughly discussed at the next meeting of the Local Conciliation Board.

Mr. T. Lindley reported upon the preliminary arrangements made in connection with the forthcoming visit of the Belgian Master Builders' visit to Sheffield. These were as follows: Arrive at Victoria Station, Sheffield, Tuesday morning, second week in August, a civic welcome being extended to them by the mayor and corporation. Various large works to be visited in the afternoon, followed by a banquet. Wednesday, visits to large steel works, and drive, probably to Chatsworth House. A hearty invitation is given to all members of building trades Federations to attend.

BATH ASSOCIATION.

Secretary: E. J. B. Mercer.

On June 23rd, members of the Bath Association and their friends (the party numbering sixty-five), had their nineteenth annual outing, when, as was reported in last week's issue, Torquay and Paignton were visited. Upon reaching Torquay they received a hearty welcome from the corporation. Mr. Councillor Smerdon (three times mayor), acting on behalf of the mayor, who was unavoidably absent, gave a cordial greeting to his brother builders, and wished them a happy day. The corporation hospitably provided four four-in-hand char-a-bancs, in which, accompanied by various members of the corporation, the visitors drove round the borough. Upon their return from the drive, the members of the Bath Association, now joined by several members of the Torquay corporation as their guests, lunched in the large hall at the museum, that being the only room available for the number. After the luncheon, the party went in motor 'buses to Paignton, where they were heartily welcomed by Mr. H. Parnell, the chairman of the Urban District Council, and for an hour or so a number played cricket and bowls in the Queen's Park, which had been placed at their disposal by the council. At 5.20 the party adjourned to the Pavilion, where high tea was served, the president being in the chair. The party started on the return journey at 7.40, and arrived in Bath soon after 12 midnight. The arrangements were made by Messrs. S. Ambrose and E. J. B. Mercer, secretary.

BIRMINGHAM ASSOCIATION.

Secretary: E. J. Bigwood, J.P.

A committee meeting of the Birmingham Building Trades Employers' Association was held at 17 and 19, Colmore Row, Birmingham, on Wednesday, June 23rd. Mr. F. G. Whittall, president of the association, presided, and there were ten other members of the committee present.

Mr. J. J. Moffat reported that he had met the city surveyor and discussed with him the new by-laws of the city council. He pointed out to the committee the alterations from the old by-laws, and was asked to arrange to meet the city surveyor again.

The secretary reported that at the annual meeting of the Local Conciliation Board it was decided that the labourers should be represented on that board. Messrs. A. H. Loud, Guy Sapcote, and G. Percy Trentham were elected to fill the vacancies on the employers' side of the board.

The president was asked to represent the association on the Provisional Committee of the Midland Counties Property Protection Society.

A deputation was appointed to attend the funeral of the late Mr. Thomas Barnsley, J.P., and the following resolution was passed:—"That this committee desire to express to Mrs. Barnsley and family their deep sympathy with them in the great loss they have suffered by the death of Mr. Thomas Barnsley, and their high appreciation of the valuable services Mr. Barnsley has rendered to this association and the trade during the last fifty years."

It was decided to renew for another session the prizes in builders' quantities, carpentry, and joinery, drawing, practical sanitary science, and masonry, at the Municipal Technical School.

Forty new members were elected.

The annual excursion of the association was held on Tuesday, June 29th. The party took train to Droitwich, and then drove through Ombersley to Holt Fleet; lunch was taken at the Holt Fleet Hotel, and the company afterwards journeyed by the steamer "Duchess of York" through Worcester and Upton-on-Severn to Tewkesbury, where dinner was served at the Bell Hotel. The number was not as large as was anticipated, but this was doubtless due to the inclemency of the weather in the early hours of the morning.

BLACKPOOL ASSOCIATION.

Secretary: W. A. Clarke.

As a result of the notice given by the operative joiners for an increase in wages and various alterations in the working rules, and of the counter-notice given by the Master Joiners for a reduction of ½d. per hour and alterations to rules, the matter has come before the Local Conciliation Board, but although four meetings have been held, no agreement could be arrived at, and the dispute has been referred to the Northern Centre Conciliation Board.

HULL ASSOCIATION.

Hon. Secretary: A. Peers.

The annual picnic of the Hull Association took place at Pateley Bridge, when about 90 members and friends formed the party, which left Hull at 7.20 a.m., arriving at Pateley about 10 o'clock. After a hot luncheon at the King's Arms Hotel, the visitors drove in carriages to Howstean Dock, where the afternoon was spent. The drive gave the members the opportunity of viewing the compensation reservoir belonging to the Bradford Corporation, and many diversely interesting objects. At 8.15 p.m. the start was made for Hull, where the party arrived soon after 11 o'clock.

LEIGH AND DISTRICT ASSOCIATION.

Secretary: S. Wigham.

The half-yearly meeting of Leigh and District Association was held at Higson's Restaurant, Market Street, Leigh.

The following were elected members of the association:—Messrs. Langley and Annett, joiners, Atherton; Mr. J. Tildesley, joiner, Atherton; Messrs. Clarke and Mather, joiners, Glazebury; and Mr. G. Moss, joiner, Leigh.

It was decided to adopt the following rule: "(*a*) Any member of this association found infringing any of these rules shall, upon receiving not less than two clear days' notice in writing from the secretary respecting such infringement, appear before the committee and give an explanation of his conduct in respect to such violation of the rules; and should his explanation be deemed unsatisfactory, the committee shall be empowered to fine or otherwise deal with him as they think proper, subject to his right of appeal to a general meeting if he considers he has been unjustly dealt with. (*b*) But should a member refuse to pay a fine, or disobey in any other way the directions of the committee, they may then report him to a general meeting of the association, when he may be expelled by a majority of votes of those present, if due notice of proceeding under this rule has been given on the circular calling the meeting."

LLANDUDNO AND DISTRICT ASSOCIATION.

Secretary: E. P. Morris, Accountant.

On July 22nd the members of the Llandudno Association held their annual excursion, when Llangollen was the venue. A motor char-a-banc left Llandudno at 9 o'clock. Proceeding through Abergely, past Gwyrch Castle (the seat of Lord Dundonald), the party stopped at St. Asaph for refreshments, and then went on past Denbigh to Ruthin, where a further halt was made in order to inspect the new county buildings. The party then proceeded through pretty scenery to Llangollen via Corwen. After luncheon they visited Bryntysilis Church, where there is a tablet recording the fact that Robert Browning worshipped in the church. A start was made for home at 4.30, and Llandudno was reached, via Bettws-y-Coed and Llanrwst, at 9 o'clock p.m., after a most enjoyable ride of 115 miles.

LONDON MASTER BUILDERS' ASSOCIATION.

Secretary: T. Costigan.

An emergency committee meeting of the London Master Builders' Association was held at 31 and 32, Bedford Street, Strand, W.C., on Monday, June 7th, 1909.

The president (Mr. F. G. Rice) was elected to serve as the representative of the association at the conference on taxation of land values, to be held in the Queen's Hall, Langham Place, W., on Tuesday, July 13th next.

The president (Mr. F. G. Rice was elected to serve as the representative of the association on the Home Office Departmental Committee on dangers of white-lead poisoning in house decoration.

The Organisation Committee met on Thursday, June 10th, and also on Thursday, June 17th. Mr. F. Higgs was elected chairman of the committee. Sub-committees were elected, and maps of the district were considered and determined upon.

The Joint Office Premises Committee met on Tuesday, June 15th. Several premises were considered. It was decided to recommend to the council the acceptance of the third floor of the building about to be erected at the corner of Kingsway and Kemble Street.

The Finance Committee met on Thursday, June 17th. The financial statement was submitted and considered, and routine cheques were drawn.

A Council Meeting was held on Thursday, June 17th. Reports from the Emergency Committee, the Organisation Committee, the Office Premises Committee, and Finance Committee were read and approved.

The recommended new offices were unanimously approved by the council. They will be ready for occupation in about twelve months' time.

The visit of master builders from Brussels and Antwerp was reported, and inquiries were ordered to be made connected with it.

SHEFFIELD ASSOCIATION.

Secretary: T. Smith.

The monthly meeting of Sheffield Master Builders' Association was held on June 10th, Mr. W. W. Mears presiding.

Mr. Forsdike reported that the deputation which had waited on the town clerk and city surveyor with reference to the proposed substitution of the city council's ordinary form of contract for small jobs, instead of the short, simple form of contract heretofore in use, had been most favourably received. They had agreed that it was unfair to impose the clause providing for 5 per cent. of the contract price to be retained for 6 months and a further 5 per cent. for 12 months in jobs of this kind, and that all jobs up to £100 in value be settled within 3 months; and it had also been tentatively agreed that jobs of £1,000 value should be settled within 6 months. The deputation had pointed out that it was manifestly impossible for a contractor to be responsible for woodwork done hurriedly for a period of 12 months, as no amount of care could prevent some shrinkage.

A report was given of the meeting with a deputation representing the Builders' Merchants Association with the object of arranging preferential prices to builders. The builders' merchants recognised the fairness of the proposal, and expressed themselves as quite willing to make some concession to builders, but pointed out that there were many difficulties. Unfortunately some builders' merchants were not members of the Merchants' Association, and these would not fall into line, with the result that they would secure the orders of those against whom prices were raised; while, on the other hand, there were builders who were not members of the M.B.A. Beyond this it was a fact that some builders were in the habit of passing the local merchants with their large orders, and using the local merchant merely for odds and ends. If the builders would agree to put their larger orders in the way of the local merchant, there would be a substantial inducement for the merchants to put such rule in force. Again, the deputation contended that there was some difficulty in determining who was a builder, and they could not very well refuse cash with order. Very large users would also buy direct if prices were put up against them. The deputation also held that brick and timber merchants should concede a similar preference. The bankrupt builder financed by another party was also a difficulty, but it was pointed out that in such a case the bankrupt builder, and not his principal, was the person properly entitled to the discount. The matter altogether seemed to bristle with more difficulties than were anticipated, but it was thought that they were by no means insuperable, and the matter was ultimately left over for further discussion by both parties, on the understanding that a start would be made with specific goods, and the preference conceded to members of the M.B.A. only, the main grievance appearing to rest in the system which permitted persons quite outside the building trade to purchase materials at the same prices as builders, and contract for the labour separately.

A report was given of the meeting of the Conciliation Board, and the several matters were discussed at considerable length. Mr. Boot took very strong objection to the way in which his firm had been referred to, and several members expressed the opinion that some apology was due on the part of the operatives.

With respect to the practice of increasing the time on the time sheets when overtime is worked, instead of increasing the rate of pay to time and a quarter, time and a half, or double time, it was held by members that the system kept the rate uniform, and was a great clerical convenience. The wage clerks did not and were not required to take cognisance of overtime, but simply made up wages at one uniform rate for each class of workmen in accordance with the hours shown on the time-sheets, which hours were fixed at the time of working. The system of paying differential rates would lead to complicated entries on the time-sheets and in the wages book, and would doubtless lead to many errors. If a workman receiving 9½d. per hour worked 6 hours on a Sunday, it made no difference whether he was paid for 12 hours at 9½d. or 6 hours at 1s. 7d. The objection of the operatives that the time-sheet might at some subsequent period make it appear that the man had worked overtime at ordinary rates was not tenable, as the time-sheets usually showed the time of commencing and finishing.

With respect to the system of making stoppages from wages to cover the premium for the first week of disablement, the secretary was instructed to ask the operatives to give any specific instances in which the system was in operation.

A report was also given of the meeting of the Trades Committee in reference to the question of proposed abolition of walking time, in lieu of which the operatives had asked for an advance of ½d. per hour, which it was unanimously held could on no account be conceded. The operatives also asked for lodging money at 6d. per night on jobs over 4 miles from Sheffield Parish Church. After a lengthy discussion, the following resolution was unanimously passed, and ordered to be sent to the operatives:—

"That lodging money at the rate of 6d. per night be paid to men sent from the contractor's place of business to work on jobs over 4 miles from the Sheffield Parish Church except in cases where by mutual agreement it is considered advisable that railway and tram fares in and out be paid in lieu of lodging money, conditionally upon the men being on the job at the official starting time, no lodging money to be paid to men set on on the job."

YORK ASSOCIATION.

Secretary: J. Hague, Solicitor.

The general quarterly meeting of the York Master Builders' and Contractors' Association was held at the Old George Hotel, Pavement, on Friday, June 11th, at 8 p.m. Mr. Biscomb presided over a good attendance.

The amended form of sub-contract was read and generally approved, but the question was postponed to a future meeting on its being mentioned that the secretary to the Northern Counties' Federation had been requested by the Yorkshire Federation to prepare a draft form incorporating the provisions of the Workmen's Compensation Act, and also the principles laid down in the suggested form.

On the question of third party risks, correspondence was read from two insurance companies. The members considered that the question was very important, and that adequate cover should be secured against what promised to become a serious liability. After a long discussion, the matter was adjourned until next meeting, in order that further information on various points which had arisen might be obtained.

The executive's recommendation as to the constitution of the Local Conciliation Board for 1909-10 was approved, and election was unanimously passed in accordance with such recommendation. The Chairman reported the result of the recent submission to the Board of a question by the operatives, and explained the present position of the working rules. Correspondence was read with reference to the proposed summer excursion, together with an offer from another association inviting a union with them in an excursion to Edinburgh and Loch Lomond. After discussion, Mr. C. Dent moved that the existing minute on the question be deleted, and that no excursion be held. Mr. G. Rawling seconded, and the motion was carried.

It was reported that since the last meeting the local case that has been previously referred to had been settled, a letter having been received stating that so far as the member was concerned, it was unlikely that any further claim would be made against him personally. The result was considered satisfactory, and it was unanimously resolved that an expression of thanks from the Association should be sent to the Yorkshire and National Federations for their assistance in the matter, which had been much appreciated

Mr. J. W. Belleby was to have moved a question having reference to an addition to accounts rendered, for work done, of a percentage on account of heavy premium for compensation insurance of workmen. In the unavoidable absence of the mover, the Chairman introduced the question to the meeting, and a long discussion followed. Finally, Mr. Lacy moved, Mr. Dodsworth seconded, and it was carried, that the question be adjourned until next meeting, in order to allow of the original mover being present and the question re-opened.

Two questions relative to breach of rules were brought forward, the matter being left to the executive to deal with.

Correspondence was read between the Secretary and the Clerk to the Cemetery Company with reference to an application for a rebate on increase in fees charged for memorials taken into the cemetery by local masons between January 15th and March 31st last. The secretary's action was approved.

New Companies.

BRITISH IMPROVED CONSTRUCTION COMPANY, LTD.—Registered June 26th, by Bircham and Co., 46, Parliament Street, S.W. Capital £100,000, in £1 shares (20,000 Cumulative Preference, 30,000 Ordinary, and 50,000 Deferred). Guy Street Saw Mills, Padiham, Lancashire.

"I only wish I had your chance
—I wouldn't now be working hard
and long, for little pay, at 60."

Take the Old Workman's Advice.

Don't let *your* life be one constant round of drudgery, as *his* has been. If you do, you will assuredly experience bitter self-reproach, as well as dissatisfaction, for *you can*, to-day, rise out of the rut, if you only *will*, although the old workman couldn't in his day. Grasp the opportunity of securing a better post and a higher salary through the International Correspondence Schools.

The I.C.S. exist for the one and only purpose of training ambitious men for more remunerative positions, by means of home correspondence study. Every month, students voluntarily report advancement as a direct result of I.C.S. training. Read just this one letter for example:—

"Altrincham (Lancs.)

I cannot help but be grateful for the great benefit I have received by means of the Course of study (Mechanical) pursued with your Institution. Not only has it been helpful to me in my own work, but I have constantly observed that many of my associates have succeeded in business mainly through the I.C.S courses of study. I heartily recommend all ambitious young men to enrol themselves with the I.C.S. (Signed) THOS. W. WINSTANLEY."

Note also that, besides thoroughly training you, we do everything possible to help you right into a good post. Our

"STUDENTS' AID DEPARTMENT"

is in touch with employers in every district, and furnishes I.C.S. students with valuable introductions, recommendations, etc.

With such bright possibilities before you, you will surely not be content to settle down to a disappointing round of toil such as the old workman's lot has been!

Embrace the opportunity afforded by the I.C.S.

Mark the coupon, or write us about any special career, and ask for full particulars of our "Students' Aid Department"—NOW.

and Detroit, U.S.A.

Fulwell Hydrated Lime.

A high-class Lime, slaked by a patent process, and packed in bags. Saves the labour of washing and running the lime, will not blow, leaves no waste, may be stored without deterioration and without bursting the bags.

For mouldings and lathwork can be gauged with a much smaller proportion of plaster than ordinary lime.

Converts lime into a safe, reliable and convenient material with the advantages of a bagged plaster.

Further Particulars and Samples from:—

The Exors. of the late
Sir HEDWORTH WILIAMSON, Bart.
Fulwell Lime Works, SUNDERLAND.

Architects for the Royal Academy.

The Royal Academy of Arts having been founded in 1768, with Sir Joshua Reynolds as its first President, any complaint that it does not fully justify its comprehensive title, and has never accorded due recognition to the Mistress Art, would probably stimulate architects to no stronger action than "a patient shrug; for sufferance is the badge of all our tribe." We have no intention of raising such an issue. We have the utmost respect for the dignity of the Royal Academy, and any desire to impugn the wisdom of its polity and its practices and pursuits is very remote from our present purpose. We have in view for the moment what is surely a more interesting object, and one that seems to us to be not only entirely void of offence, but to possess a considerable measure of practical utility. It will be granted as being well within the bounds of possibility that the Royal Academy, being a human institution and therefore fallible, cannot and does not invariably select the indubitably most worthy man on whom to confer the honour and dignity of membership or associateship; and that, for rather cogent reasons, its judgments with respect to architects do not always commend themselves to the profession that is most interested in them. Of course, in any case, the elect of the elect is not always, nor perhaps very frequently, coincident with the popular choice. Hence have arisen such significant expressions as "the poets' poet," "the preachers' preacher," "the novelists' novelist;" the form of words suggesting, what is sometimes conspicuously true, that the popular choice of an idol is not necessarily identical with professional preference. In considering these phenomena, it has occurred to us that there is probably in existence, perhaps unsuspecting and unsuspected, "the architects' architect," and we think that it would be, from many points of view, exceedingly interesting to discover his identity. That revelation, however, would be a sort of secondary issue of the scheme that has been suggested to us and that we have decided to put into operation. The primary object of that scheme is to ascertain whom the properly accredited architects themselves would elect if the choice were theirs, and the ultimate aim is by this means to afford guidance which the real Royal Academy electors will no doubt gladly welcome. Accordingly we are putting this issue to the vote. If the interest aroused by this plebiscite is at all commensurate with our own candidly confessed eagerness to ascertain who are the fortunate half-dozen whose work and worth find most favour in the eyes of their professional brethren, and to discover who will head the list as "the architects' architect," the complete success of our plebiscite is assured. We are very earnest in the desire that the opinions thus elicited shall be of practical use to the Royal Academy, and we feel confident that those whom we are inviting to take part in this plebiscite will respond in the same sincere spirit. Full particulars appear on p. 27.

Brentford's Blockade.

There were once upon a time, so runs the legend, two Kings of Brentford reigning contemporaneously and amicably. Has not George Villiers, Duke of Buckingham, celebrated in his "Rehearsal" some of the more dramatic moments in their lovely lives? The habit of congestion seems to have clung to the town; for in the High Street, which is so narrow as to suggest a fleeting doubt as to whether the two kings, neither of whom—they being the politest of monarchs—would have cared to take precedence of the other—could have traversed it abreast. We have been favoured with a copy of the "West London Illustrated Advertiser" (Walter Pearce and Co., St. George's Press, Brentford), in which it is shown, graphically as to the language, and photographically as to the illustrations, that, while High Street, Brentford, is architecturally and in some other respects emphatically an excellent place to get away from, the gratification of that very natural desire is not always so easy and simple of accomplishment as one feels entitled to expect in a civilised country. It is apparent from the pictures that in certain parts of this "main artery from London" there is not room for three vehicles abreast. "It is no uncommon thing," we are informed, "to see the narrow roadway choked with an ever-increasing multitude of commercial drays, traction engines, heavy waggons conveying market garden produce from distant western suburbs to the London markets, continuous streams of electric cars, and innumerable processions of motor cars of every description, all jumbled together in endless confusion, and unable to move in any direction." Five years ago, it is stated, the District Council were seeking powers to widen the High Street, but nothing has been done. Possibly the Council jibbed at the expense, as well they might. At this point, again, the case assumes more than local importance. It is obvious that only a very small proportion of the traffic is purely local. The necessary expansion of painfully constricted "main arteries" should certainly be a national concern. It is iniquitous and absurd to throw on a small town, or even on a large county, the burden of expense involved in forming and maintaining highways that are really national. The Town Planning Bill may remove this injustice; but in the mean time there is likely to be much lamentable delay of vegetable produce in the straits of Brentford High Street; and the many motorists arrested by those traps will be heavily penalised by inability to drive away furiously from the horribly depressing old houses that here and there affront the High Street. That these houses must necessarily be demolished when the High Street is widened is a potent reason for expediting this very necessary improvement.

The Geneva Memorial.

The Calvin Memorial at Geneva, which was unveiled on July 6th, is part of the great memorial to the heroes of the Reformation. The first stone of this great monument has been imbedded in the wall of the rampart built in 1543, which faces the University. The scheme is imbedded in faith, which faces the necessity of raising £24,000 before the monument can be completed. It is not likely that the scheme will either languish or be curtailed for lack of funds; the appeal being international if not worldwide, as the figures that are to be represented on the monument proclaim by their mere names—for instance, Farel, Calvin, Beza, Knox, Cromwell, and Roger Williams. Moreover, at the unveiling ceremony, speeches were delivered by Lord Kinnaird, who is Lord High Commissioner of the Church of Scotland, and by delegates from the Grand Duchy of Baden, Hungary, and Moravia; while the Emperor of Germany contributed a telegram expressing his pleasure at the inclusion of effigies of three of his noble ancestors—Coligny, William of Orange, and Frederick William of Brandenburg. This should loosen the purse-strings in Germany; and on the whole there seems to be no reason for apprehension that the monument will be shorn of its full artistic splendour for lack of "a few rascal counters."

Teutonic Town-Planners. Two hundred members of the German Garden City Association are now visiting this country in order to see what we are doing in the way of practical town planning. Yesterday they were received by the President and Council of the Royal Institute of British Architects, whose hospitality, ever charming, is on this occasion only too obviously disinterested and detached; because the R.I.B.A., as a body, has not been hitherto conspicuous in the van of the town-planning movement. This detachment is not attributed to the R.I.B.A. as a fault. The one other notable occasion on which they have actively manifested their interest in the movement—when they proffered their assistance to Mr. John Burns in relation to his Town Planning Bill—they suffered something that bore at least a distant resemblance to a rebuff that was as ungracious as it was undeserved; and in what other ways they could have demonstrated their interest in town planning would perhaps be difficult to indicate. They are, at any rate, entitled to congratulation on the tactfulness—beyond question free from all taint or suspicion of mere diplomacy in any sinister sense—with which they have seized upon the present occasion to show that they are finely responsive to the amentities of international amity, and that they are at least awake to the importance of town-planning. The visit of our German guests may possibly stimulate the R.I.B.A. to more energetic action in this direction. Our German friends are of course visiting Letchworth; which, equally of course, they, coming of a highly critical race, will not regard as a final solution of the problem, or as a model for all time and all circumstances. They will no doubt admire there the pleasant gables, porches, verandahs, latticed windows, smiling gardens; but they will regret the smallness of some of the rooms, will find fault with some rather inconvenient planning, and will wish the inhabitants a double portion of Teutonic patience with which to await the growth of the forty-five thousand trees that have been planted, and pending whose maturity, as well as the addition of many more buildings, the first Garden City must wear that general air of incipiency which is so fatal to serenity and comeliness. They will probably think that, as the Cockney is wont to say of London, which, by the way, will show our visitors that it has never quite thrown off all traces of its former glories as a vast Garden City—Letchworth "will be a fine place when it is finished."

Dignity at a Discount. With the holidays upon us, it is perhaps a not unseasonable remark that it is not always possible to say offhand whether the tide is coming in or going out. What of those art waves of which we have recently heard so much? Down Torquay way, there is some slight indication that there is at any rate a considerable stretch of rather arid sand, and a goodish bit of very stony beach, on the foreshore. Torquay, it seems, is "still coquetting with its scheme for erecting municipal buildings and a pavilion," and it is strongly urged by a writer in a Devonshire paper not to be like the wave that wavereth, but to "make a strenuous bid for popularity with holiday keepers from all parts of the country." Yet the writer who advises this heroic course appends an admonition that raises in our mind the floating doubt indicated in our opening sentence. "Money," he declares, very candidly, but somewhat hortatorily, "should not be spent on luxuries, or merely to enhance municipal dignity, but no reasonable expense ought to be spared on projects likely to enhance the attractiveness of the town." If what will enhance municipal dignity will not also enhance the attractions of the town, so that the council would be wordly-wise in throwing dignity to the dogs, and in putting up some horrific structure that should shriek aloud for the suffrages of the many-headed mob, with a frank "Philistia, be thou glad of me!" why, chaos is come again; for if dignity is so belittled in genteel Torquay, what ragged remnant of hope is left for vulgar—— The blank may be filled in in accordance with individual preference—one dare not say taste.

Decorations and other Orations. Master house-painters and decorators are an enterprising band, and are sociable and clubbable withal. The London Association of Master Decorators have held their first annual meeting, and have achieved their first annual dinner; while the National Association of Master House Painters and Decorators of England and Wales are busy in preparation for their annual convention, which is this year to be held in Sheffield, in September, and includes an exhibition, which is to be formally declared open by Sir William Richmond, R.A., who also has promised to deliver a lecture on some phase of decorative art; while the Worshipful Master of the ancient City Company of Painter Stainers will be present at the annual dinner, when, if (as seems antecedently improbable) he holds with the poet that "the form, the form alone is eloquent," he will find that there is a good deal to be said in favour of colour, and that the decorators are capable of saying it with a degree of oratorical fervour that justifies our heading. High art, indeed, as Sir William Richmond will allow, is not incompatible with the use of a long ladder or a Palmer's cradle; and, speaking of cradles, one is reminded that the National Association is fostering an excellent nursery of decorative art. It is offering this year nearly £90 in prizes for the work of apprentices, and will inaugurate a prize scheme for young men, who, being out of their apprenticeship, but not more than twenty-five years old, may compete for valuable prizes and scholarships. The Association has also established travelling scholarships, the winners of which go to Italy to study the masterpieces of decorative art. Perhaps it is not incompatible with these high and noble aspirations that the Association does not, apparently, disdain to encourage the curious art of marbling; which, if 'tis done, 'twere well 'twere done quickly—and as artistically as may be; although it is at best a form of decoration that is of doubtful decorum.

NATIONAL FEDERATION OF BUILDING TRADE EMPLOYERS.

As announced in previous issues, the half-yearly meetings of the National Federation are to be held next week at Portsmouth. On Tuesday, July 20, the Council meeting will be held; and on the next day (Wednesday) at 10.30 a.m., the general meeting is to be held in the Grand Jury Room at the Town Hall. Reports of the proceedings will be published in due course.

Architects of the Day.

II.—Mr. Ernest Newton, F.R.I.B.A.

Though our modern public and civic architecture cannot in the main vie with that of our near neighbours the French, or our cousins, three thousand miles removed, the Americans, yet the fame of our domestic work has spread into all lands, and it is particularly appropriate therefore to devote an early article in this series to the work of so talented an exponent of domestic architecture as Mr. Ernest Newton. To his work and to that of some of his immediate friends and contemporaries we owe a renaissance in English house architecture that is the object of study and admiration among the continental nations. Such painstaking and monumental works as "Das Englische Haus," by Herr Muthesius, bear witness to the interest which our English dwelling excites in German art circles.

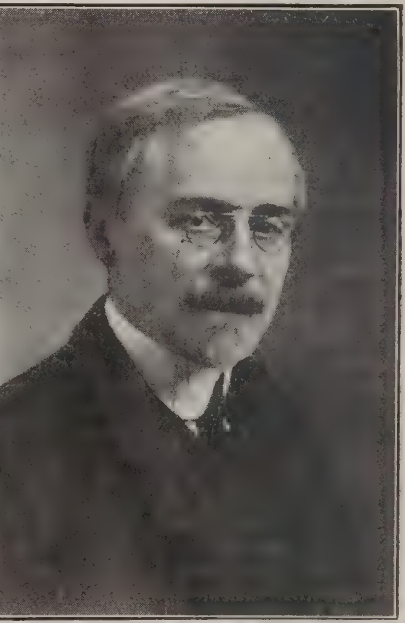

Photo: Elliott & Fry.

MR. ERNEST NEWTON, F.R.I.B.A.

Commencing with a few formal particulars, we may mention that Mr. Newton was born in London in 1856, and was educated at a preparatory school at Blackheath, afterwards proceeding to Uppingham, which famous old public school he left in 1872. In the following year he was articled for three years to Mr. Norman Shaw, R.A., and at the conclusion of his term stayed with Mr. Shaw for a further three years, after which he commenced to practice on his own account. Mr. Newton has been particularly identified with movements tending to the better education of architects and the public. In his early years of practice he was a member of the Architectural Illustration Society, which, for its ultimate object, was designed to raise the standard of work selected for illustration in the technical papers. At that time Mr. Newton tells us the building papers published most things sent up to them, without very much regard to artistic merit in the buildings depicted. The modus operandi of the Society was to invite illustrations of good work from various architects, and under the imprimatur of the Society to publish them as plates in one of our contemporaries. The arrangement continued in force for some years, and was not without its educational effect, both on architects and editors.

Mr. Newton was also closely identified with the formation of the Art Workers' Guild, which began in quite a small way in the early eighties. It grew out of a small society known as the St. George's Art Society, and was originally limited to architects, the meetings being held in Mr. Newton's offices, then situated in Hart Street, Bloomsbury. Later on followers of other arts and crafts were admitted, and now it is a flourishing society, with headquarters at Clifford's Inn Hall, has celebrated its half-jubilee, and has promising offspring in the shape of a junior guild.

In more recent years Mr. Newton became a member of the Honorary Editorial Committee of "The Architectural Review," and, probably no magazine has ever been produced under more influential or authoritative direction. A committee which included, beside Mr. Newton, such architects as Mr. Norman Shaw, Mr. John Belcher, Professor Reginald Blomfield, Mr. Mervyn Macartney, Mr. Halsey Ricardo, Mr. Edward S. Prior, and, for literary direction, Mr. D. S. MacColl, now keeper of the Tate Gallery, was destined to create interest and command attention in even the limited fields of architectural journalism; and, as one who was privileged to assist the committee in its deliberations, the writer can testify to the pleasure and value of those round-table lunches at the Savoy, for the meetings of the committee were planned on the model of the well-known "Punch" staff dinners. It is difficult of course to estimate the exact effect of the committee's work at this date, but we are inclined to credit to it a considerable share of the awakening public interest in matters architectural; and in the domain of architecture there is little doubt that the very considerable attention bestowed by the committee on the subject was instrumental in leading to the present forward movement in architectural education.

Mr. Newton's windows in Raymond Buildings look out over that beautiful expanse of green grass and trees that the Honourable Society of Gray's Inn so creditably preserve; and while, on a recent June morning, our artist waited for sufficient light, we admired the prospect and discussed a number of subjects with Mr. Newton of more or less topical importance.

The establishment of a Ministry of Fine Arts has long been a subject of interest to architects, and very divided views are held upon the subject. Remembering how strongly the "Review" editorial committee had advocated the appointment of a Minister of Fine Arts, we ventured a question on this topic. Mr. Newton was favourable—"provided," he added, "that such a minister was assisted by a committee of competent architects, painters, and sculptors."

Though architectural education has of late developed amazingly, Mr. Newton feels that it is not quite definite enough or long enough. "We want something big to work up to: something more advanced and on the Beaux Arts lines. Though our students are 'tremendously strenuous,' they too soon drift into practice." He thought the Beaux Arts system of pupils attaching themselves to the very big men was a good one; the prestige of these men and the veneration in which they were held by their pupils was quite remarkable. "I am afraid," added Mr. Newton, drily, "that our big men over here do not for many reasons appear such heroes to their pupils." Of the merits of a previous University education Mr. Newton was not so certain. He felt that the University man, if he has already earned distinction at the University, might find it difficult to begin again with the A B C of architecture, and it is not easy to devise a scheme of education by which architecture can be so presented to him as to make him enthusiastic and carry him through the drudgery of the early stages.

On the question of competitions, Mr. Newton had a good deal to say. "I doubt if all competitions should be open. They should be for buildings up to—say— £20,000, but for the bigger ones, invitation is better in my opinion; and I would even go so far as to give commissions for many big buildings without any competition. My idea is that the young man would get his chance with the smaller buildings up to £20,000. If he makes his mark he gets into the invited class, and if he is successful here he has the opportunity, when mature, of doing a big thing without competing. As things are now the young man gets buildings that are really too big for his experience. I admit a few exceptions, of course. But, by the time he has made his reputation and—shall we say—ripened, he is practically shelved, as no one in that position will, or can, waste his time in open competitions. The result is, speaking generally, that the biggest buildings are not done by the biggest men. I will admit that the biggest men are not necessarily the best, but if they worked their way into their positions, as I suggest, I think they would usually be found worthy of their eminent position."

The subject of competitions is, in Mr. Newton's view, more or less bound up with that of registration, to which topic we naturally alluded. Mr. Newton thinks that the "competition mania," as he terms it, has done much to lower the status of the architect. Public bodies institute competitions among architects in much the same way as they invite tenders for the supply of bread and potatoes. On the other hand, if a painter or sculptor is to be employed, he is generally commissioned direct, and a mature man with a reputation is selected. In his opinion the professional status of the architect is fully defined; what is needed is the recognition of architecture as an art, and of architects as artists. This can only be achieved by doing good work, and Mr. Newton believes that good work "in bulk" has only been done comparatively recently. He cites the illustrations given in the professional journals of thirty and forty years ago as evidence of the fact. Though he does not suggest that good work was unknown forty years, ago, it was small in quantity compared with the mass of undistinguished work that was current architecture then.

Mr. Newton holds strong views—views that are pretty generally shared by his brother architects—on the land taxation proposals in the present Budget. There is no doubt that these proposals, coming on the top of the

1. Dining room. 3. Store. 5. Coal. 6. Yard. 7. Pantry. 8. W.C. 9. Knives and boots. 10. Larder. 11. Servants' Hall. 12. Scullery. 13. Kitchen. 15. Lavatory. 16. Entrance lobby. 17. Hall. 18. Drawing room. 19. Study. 20. Billiard room. 21. Bedroom 22. Bathroom. 23. Dressing room. 24. H.M.C.

long continued depression in the building trade, are calculated to affect architects and builders severely, and have, in fact, already had that effect, as numerous reports we have received testify. The proposal to make "the rich people poorer," is not one that architects can endorse, since, as Mr. Newton, points out, architects must be employed by rich people or by the State; and the State has not yet given any sign of its intention to act the part of a fairy godmother. An architect, like Mr. Newton, whose practice is so largely concerned with the better class of domestic work, must be directly affected by these proposals, and Mr. Newton fears that the passing of the Finance Act will probably prohibit the erection of the smaller country mansion, costing from £10,000 to £15,000, and with the disappearance of this class of house will vanish much of that quiet country life for which England, in the past, has been famous.

Asked for a list of his principal works, Mr. Newton demurred to such a formidable request, but kindly furnished, to use his own word, a list of "samples." This includes Buller's Wood, Chislehurst; Redcourt, Haslemere; Glebelands, Wokingham; Steep Hill, Jersey; house at Ewhurst; Dawn House, Winchester; Ardenrun Place, Surrey; St. Swithin's Church, Hither Green; chapel, House of Retreat, Clerkenwell; tower and spire, St. George's Church, Bickley and Martin's Bank, Bromley. Of the last- named charming little street front Mr. Newton has, in the course of his walks abroad, met with at least two close copies, a flattering but by no means gratifying distinction.

In the bare recital of these various facts and opinions we have not been able to give instances of the dry and sprightly wit which Mr. Newton exercises, too often at his own expense. He is a charming conversationalist and those who know him well will bear us out in saying that a chat with him carries pleasant memories and unfailing delight.

LONDON MASTER DECORATORS.

The London Association of Master Decorators have held their first annual general meeting at the Holborn Restaurant, when a large number of members were present. The president, Mr. H. A. Campbell, made some interesting statements as to the useful work done by the association during the first year of its existence, and dealt at considerable length with the work which it has in hand for the current year. The following office bearers were re-elected:—President, Mr. H. A. Campbell; vice-president, Mr. John Anderson; treasurer, Mr. J. J. Honeychurch. The first annual dinner of the association was held under the presidency of Mr. H. A. Campbell, at the Holborn Restaurant, on Thursday, June 10th, when about 50 members and a few friends were present. Amongst the guests were Mr. J. D. Crace, president of the Incorporated Institute of British Decorators; Mr. J. Puttrell, president, and Mr. W. G. Sutherland.

REDCOURT, HASLEMERE. LOGGIA TO WINTER GARDEN. ERNEST NEWTON, F.R.I.B.A. ARCHITECT.

This is a very delicate and characteristic piece of Mr. Newton's work. The house is built of red Wrotham bricks and roofed with red Wrotham hand-made tiles. The stone is Portland. The gutter and down-pipe are of cast lead.

Notes and News.

The junction of the Boulevard Haussmann, one of the finest thoroughfares in the French capital, with the main system of boulevards has been brought nearer by the decision of the Municipal Council to acquire a block of buildings in the Rue Taitbout. These buildings are to be pulled down when the various leases expire at the end of the next two or three years, and the Boulevard Haussmann will thus be carried all the way through to the Rue Laffitte, across which it is ultimately to be linked up with the Boulevard des Italiens. Some of the ground now acquired will be available for building sites, the enhanced value of which will enable the Council to reimburse itself in large part for the cost of acquiring the existing block of buildings. The Place du Carrousel in the Tuileries Gardens, which had for many months been boarded up with unsightly wooden pailings, is once more open to the public view. The new ornamental flower beds and lawns with which the space between the Pavillon de Rohan and the Pavillon de Lesdiguières has been laid out considerably add to the amenity of this part of the grounds.

* * *

Mr. Lloyd George has received a deputation from the Garden City Association, which placed before him the points on which it was thought that the Budget would affect garden city schemes. One of the points urged was that land which was not built upon in accordance with the settled plan of development should not be treated as undeveloped land for the purposes of the tax, although no buildings are erected upon it. Another suggestion the Chancellor of the Exchequer was asked to consider was that every provision should be made to ensure that the carrying out of a town-planning scheme should not entail loss by the owner consequent on his leaving the land unbuilt upon. Mr. Lloyd George replied to the deputation, but his reply is to be regarded as confidential.

* * *

We are informed that Nicholas, Denyer and Co., 43, Pall Mall, S.W., have just sold nearly four acres of freehold building land adjoining Rickmansworth Park, this being the only lot left over from their auction sale held at Rickmansworth on June 26th.

* * *

The famous old farmhouse at Kirkton, Fraserurgh, which figured prominently during the Jacobite rebellion, is being demolished to permit of the extension of Fraserburgh Cemetery.

* * *

In the House of Commons, Mr. Sloan having asked the Chancellor of the Exchequer whether the proposed central road authority referred to in the Finance Bill is to be a Crown nominated board or a popularly elected one, and when he proposed to bring it into existence, Mr. Lloyd George (Chancellor of the Exchequer) in reply says: I hope that a Bill embodying the proposals in connection with roads which I laid before the House in my Budget speech will shortly be introduced, but until this is done it would perhaps be premature to answer the question put by the hon. member.

Owing to its bearing no identification inscription, probably few of the many thousands who daily passed the equestrian statue of George IV. in Trafalgar Square have known whom it represented. The Office of Works has just caused this omission to be rectified, and the words "King George IV." have been inscribed in gilt lettering on the Aberdeen granite pedestal, together with the name of the sculptor (Sir Francis Chantrey). This statue, which represents the King wearing a wreath of laurel, and riding his charger without stirrups, had a somewhat curious origin. It was ordered by King George himself, and was commenced in 1829, the price agreed upon being 9,000 guineas. The King paid the first instalment in the following year, and the last was paid by the Lords of the Treasury in 1843, after the death of both King and sculptor. The original intention of King George was to have the statue mounted on the Marble Arch, which then stood in front of the main entrance of Buckingham Palace.

* * *

"Inside Facts about Saxon Portland Cement," a neat and useful booklet, which we have previously noticed, now appears in a second edition. The booklet includes a most interesting account of the processes of manufacture, with illustrations of the firm's premises and plant, and of some important works on which their cement has been or is being used. The firm have also issued a separate list of such works, in which it is shown that among the most extensive users are the Admiralty, the War Office, H.M. Office of Works, the General Post Office, the London County Council, and a large number of corporations, railway companies, tramway and waterworks companies, and other public undertakings; and that it is employed in the construction of innumerable churches, schools, theatres, etc. These publications are to be had from the Saxon Portland Cement Co., Ltd., Cambridge.

* * *

The effect of arches as an addition to street architecture could be fairly well judged from the erections which were placed across the roadways during the recent Royal processions at Birmingham and elsewhere. A correspondent of the "Birmingham Post" points out that while collectively a very large amount of money is spent on such objects, artistically the result achieved is unfortunately very small. For this money a permanent memorial of the visit could have been erected in the form of an arch, useful, and a work of art at the same time. This is a matter that the authorities should have at heart: it would at once appeal to our neighbours abroad as an important part of city improvement schemes and town planning. Years ago, he says, in one of the original plans for the Birmingham Council House buildings, a suggestion was made for providing an archway and bridge connecting the angle of the Town Hall. By this means corporation and other Government offices have before now been brought into touch with one another. The idea, if allowed to grow, would make a square in reality of Victoria Square, or at lease an enclosure with some title to the name. In the new Art Gallery extension, Birmingham will soon have a bridge and arch to serve a useful purpose; its position is not sufficiently central or important, but it may tend to lead the way to others. Our cities are sadly lacking in enterprise of this kind. It does not appear to be always a question of funds; it is more a matter of getting the best and most permanent value for the money actually expended. One can only regret this opportunity as one of wasted effort.

* * *

The building trade in the East Northumberland districts appears to be on the eve of a welcome boom. At Blyth, where house accommodation has become very scarce, and rents are being raised, plans for extensive developments have been passed by the public authority. The enterprise of Lord Ridley promises to result in the erection of a large number of houses between Newsham Railway Station and the Links. At New Delaval house are going up rapidly to meet the local demand, and the same remark applies to the Bedlington district, where important mining extensions are in progress. Plans for over 300 houses at Woodhorn have been approved by the Morpeth Rural Council, and in the Hirst locality extra accommodation continues to be provided. After the lengthy period of practical stagnation in this district as elsewhere, a spell of building activity is decidedly a gratifying change.

* * *

Lord Strathcona has presented to the McGill University, Montreal, of which he is chancellor, £100,000, of which sum four-fifths will be needed for the completion and equipment of the new Medical Buildings, the old having been destroyed by fire in 1907. The remainder is intended for augmenting the salaries of the University staff.

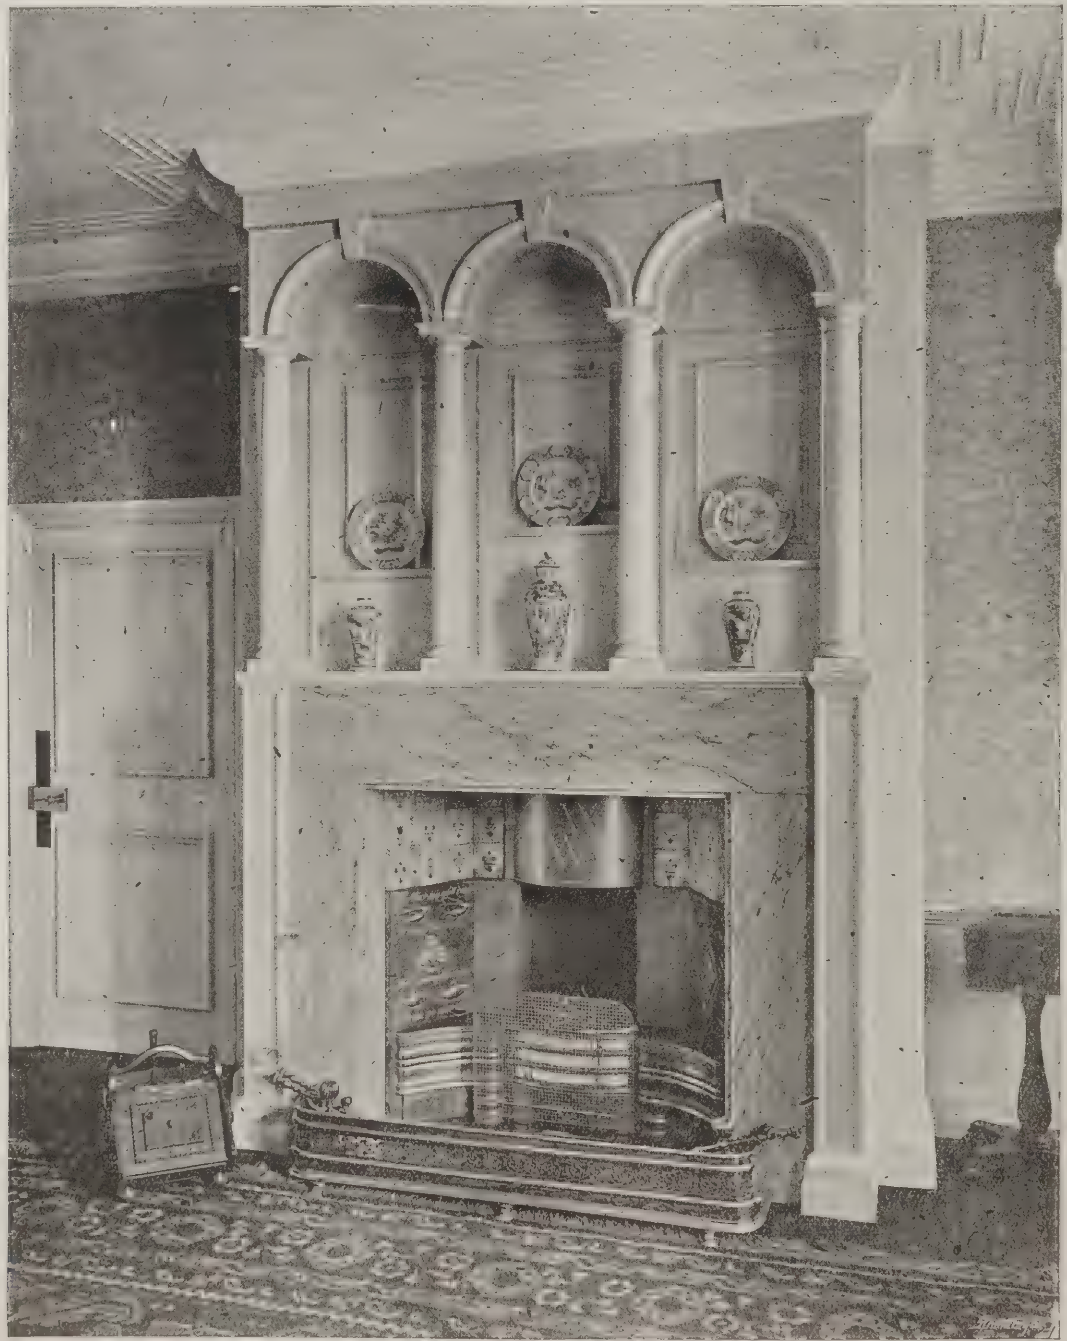

Photo: Architectural Review Photo Bureau.

REDCOURT, HASLEMERE. DINING-ROOM CHIMNEY PIECE. ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

This chimney piece is also a very characteristic example of Mr. Newton's work. The treatment of three arches on supporting columns, or pilasters forming niches, occurs in other buildings of his, as at Luckley on page 24.

The loss of life by the caving in of a trench at the Newport Dock Extension works is reported at thirty-nine, although exact ascertainment seems hardly possible. A theory that the accident may have been of seismic origin is supported by the statement that at the moment of the accident an earth tremor was registered on an instrument in a shop in Newport; but it seems to be a fair inference that the collapse of the trench, from whatever cause, may itself have set up the record.

In Parliament.

By our Gallery Representative.

The Queen Victoria Memorial.

Mr. Harcourt, the First Commissioner of Works, informed Major Anstruther-Gray in the House of Commons last week, that the work upon the Queen Victoria Memorial was proceeding, but he could not fix a date for its completion. That must depend upon the progress made. The fountains were already open to view.

The Mall Archway.

Major Anstruther-Gray inquired whether the First Commissioner could state when the archway on the east of the Mall leading into Charing Cross would be open for traffic.

Mr. Harcourt said the contract provided for the completion of the building at Christmas of this year, and he hoped to be able to open the arches shortly after the date, but the possibilities of traffic depended upon the action of the London County Council on the roadway beyond the limits of the Park and the new building.

New Shelter and Fountain in Kensington Gardens.

Mr. Stianger having asked the purpose of the octagonal building which is being erected in the north-west corner of Kensington Gardens,

Mr. Harcourt informed him that it had been erected by the generosity of a lady who did not wish her name to be divulged, in order to provide a shelter and drinking fountain, surmounted by a clock, for the use of the children who frequented Kensington Gardens. Another anonymous donor had been equally kind in providing swings and other equipment necessary for the formation of a playground for children immediately around the fountain. The fountain, which had been most carefully designed to harmonise in every essential with its surroundings, would, he anticipated, prove not only an addition to the appearance of that portion of the gardens, but also the greatest boon to the numerous children.

Portsmouth Lock.

Mr. McKenna, the First Lord of the Admiralty, informed Mr. Ashley that various schemes for the new lock at Portsmouth were prepared, and on July 16th, 1907, it was decided to adopt the scheme which was now being carried out. The first vote for its construction was taken in 1906-7, when the sum of £10,000 was provided. The estimated total cost of the lock and the connected works was £940,000, exclusive of £65 000 for machinery. The main contract was due for completion in the autumn of 1912.

Building of Technical Schools in Ireland.

Mr. Birrell, Chief Secretary for Ireland, replying to Mr. Flynn, stated that he at present saw no prospect of providing additional grants for the building of technical schools in Ireland.

The Aldersgate Street Post Office.

Mr. Tyson Wilson asked the Secretary of State for the Home Department if he could state how many fatal and non-fatal accidents had happened on the new post office in Aldersgate Street since the commencement of the work up to the present time.

Mr. Gladstone said: It has not been possible to ascertain by a search through the records of the department how many reportable accidents have occurred during the 2½ years the works have been in progress, but the accidents entered in the register kept at the works are as follow: 1 fatal, 6 serious, 36 slight

Architects for the Royal Academy: "Builders' Journal" Plebiscite.

It is common knowledge that the elections of architects to the Royal Academy have often, whatever may have been the merits of the candidates selected, by no means represented the consensus of opinion among their brother architects.

It has often occurred to us, and our view is confirmed by conversation with painter and sculptor members of the Royal Academy, that votes are sometimes given for or against architects without much previous knowledge either of the candidate's work or of his professional standing; a fact that is not surprising when we remember the painters and sculptors number 64 (as against six architects!). It is evident that the electoral power is entirely in the hands of those who can have but little real knowledge of architects. The architect R.A.'s are Messrs. George Aitchison, T. G. Jackson, Norman Shaw, and Sir Aston Webb, C.B.; Mr. John Belcher is R.A. elect; and Mr. Reginald Blomfield is A.R.A.

We have reason to believe that an expression of opinion by those qualified to judge would be welcomed by many members of the R.A. as a guide to them in their selection of representatives of the art of architecture. This plebiscite should serve an excellent practical purpose by designating in the most definite manner possible the architects who, in the opinion of accredited members of the profession, are worthy of the signal honour of election to the Royal Academy. The painters and sculptors of the Royal Academy will no doubt be grateful for such guidance, which should also greatly strengthen the hands of the architect members.

We therefore invite our readers to fill in one of the postcards which will be issued by the "Builders' Journal." The postcards must be legibly signed, and the replies of those voting will be submitted to the scrutiny of two architects of position entirely independent of this Journal, namely, Mr. A. W. S. Cross, M.A., V.P.R.I.B.A., and Mr. E. A. Rickards, F.R.I.B.A.

It is intended that bona-fide qualified architects only shall form the electorate. Voters must therefore be:—

1. Fellows or Associates of the R.I.B.A.
2. Fellows or full members of Societies allied to the R.I.B.A., but who are not necessarily members of the R.I.B.A.

As, owing to the elevation of Mr. Belcher to full R.A. honours, there is at present a vacancy for an architect "Associate," the voting is of immediate practical interest to the profession.

The decision of the scrutineers as to the admissibility of a vote is final.

The twenty names receiving the largest number of votes in the first ballot will be issued for a second vote, and the six that stand highest on the second list will be again issued for final voting. Only those who have voted in the first round will be allowed to take part in the second and third rounds. The plebiscite thus follows the method of voting adopted in the Royal Academy elections. The third and final ballot, taken on the three or four names placed at the head of the list by the voting in the second round, will decide the contest, and show who, in the opinion of the profession, is most worthy of election to the Royal Academy.

All votes will be regarded as absolutely confidential, and the voting cards will be destroyed directly the scrutineers have reported the result of the voting to the Editor.

The results of the successive ballots will be announced in this journal as soon as possible after they have been ascertained by the scrutineers.

Postcards inviting votes for the first ballot were posted to the above-mentioned electorate yesterday.

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
July 17	NEW PUBLIC BUILDINGS, BURSLEM. The Architect whose design is placed first by the Assessor will be appointed to carry out the work. Premiums of £100 and £75 to authors of second and third designs, respectively, Conditions and plan of site from F. Bettany, Borough Surveyor. Deposit, £2 2s., returnable on receipt of *bona fide* design.
July 19	WHITLEY BAY PUBLIC ELEMENTARY SCHOOL for 600 scholars, for the County of Northumberland Education Committee. *Limited to Architects practising in the County and in the City and County of Newcastle-on-Tyne.* Particulars and plan of site from C. Williams, Secretary to the Education Committee, The Moothall, Newcastle-on-Tyne. Assessor: W.H. Knowles, F.R.I.B.A., F.S.A.
July 30	GRIMSBY TOWN HALL EXTENSION. Estimated cost £26,000. Conditions of competition sent to any applicant on receipt of a stamped addressed foolscap envelope. Full particulars, schedule of requirements, plans of existing buildings, etc., on receipt of deposit £2 (cheques to be made payable to Frank Stephenson, Borough Treasurer), which deposit will be returned to those who send in designs, or if the whole of the particulars are sent back within ten days from the date of their receipt by the applicant. Premiums of £250, £150 and £100. An Architect of eminence will advise in conjunction with the Borough Engineer. Applications to be made to the latter, H. G. Whyatt, Assoc.M.Inst.C.E., Town Hall, Grimsby.
July 31	LAYING OUT ESTATE AT EASTWOOD, RENFREWSHIRE. The patrons of the Royal Incorporation of Hutcheson's Hospital, Glasgow, invite competitive designs for laying out for feuing and building their lands of Thorniiebank, containing about 195 acres. Particulars, conditions, and skeleton plans from the Chamberlains to the Hospital, Hill and Hoggan, 194, Ingram Street, Glasgow, to whom designs are to be sent. Premiums, £100, £75, £50, and £25 for the first four designs, *which will become the property of the patrons, who will not be bound further to employ the authors.* Deposit, £3 3s.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.
Sept. 20	HULL TRAINING COLLEGE FOR TEACHERS in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.

We understand that Messrs. R. Crittall and Co., 197, Wardour Street, W., are to undertake the heating and ventilating of the New Central Y.M.C.A., Tottenham Court Road.

* * *

A reredos of tinted alabaster, with white alabaster figures in high relief, designed by Messrs. J. E. K. and J. P. Cutts, honorary architects, and executed by Mr. Lawrence Turner, has been dedicated at St. Mary's, Tottenham; where also an altar tomb to the memory of the first vicar, the Rev. E. F. Noel Smith, has been erected. The tomb, which is of Caen stone, with a recumbent effigy in white alabaster, is the work of Messrs. Harry Hems and Sons.

Proposed New Works.

ABERDEEN.—Plans for the following new buildings have been passed:—Four dwelling houses on the north side of Albury Road, per Messrs. D. and J. R. M'Millan, architects; granite-polishing mill on the north side of Merkland Road East, for Messrs. Cosgrove, Lindsay, and Lawrie, per Mr. John Paterson, builder; four dwelling houses on the east side of Woodstock Road, for Mr. Joseph Shirras, builder, per Mr. Arthur C. Bruce, architect; alterations in connection with premises No. 244, Union Street, for Mr. T. R. Gillies, per Messrs. Wilsons and Walker, architects; two dwelling-houses on the north side of Mid Stockett Road, for Mr. William J. Mills, merchant, per Mr. George Milne, architect; addition to Gilcomston Milis, Leadside Road, for Messrs. John Strachan and Sons, per Mr. Gordon Forbes, engineer; business premises on the east side of Crown Street, for the Prudential Assurance Co., Limited, per Messrs. Sutherland and George, architects.

BARNES.—The following building plans have been approved:—Stable rear of No. 42, High Street, Mortlake, by Mr. W. Reynolds; store-room near No. 67, Lower Richmond Road, Messrs. John Harrison and Co.; forty houses, Madrid Road, Mr. Alfred Harvey; four houses, Lower Richmond Road, Mr. G. W. F. Bates; and new road (Milton Road), Sheen Elms Estate, Sheen Lane, Mr. Archibald Stanley.

BLACKPOOL.—It is proposed to erect new offices for the Health and Cleansing Departments of the Corporation in Sefton Street. The estimated cost is £4,000.

CARDIFF.—The Technical Schools Committee have decided to recommend the Education Authority to build a new technical instutute at a cost of £40,000.

COATDYKE.—A drill hall for the Airdrie and Coatbridge units of the Lowland Division Engineers is to be erected at a cost of £2,700.

COVENTRY.—A post-card vote has been taken in one of the wards to ascertain the feeling of the burgesses on the question of erecting a town hall. The replies show a majority of more than 80 per cent. in favour of the hall.

DEPTFORD.—The Borough Council have decided to purchase, at a cost of £5,600, a site for a central library.

DERBY.—The Education Committee has decided to ask the Town Council to purchase, at a cost not exceeding £3,000, "The Gardens," Osmaston Road, as a site for a public elementary school for 1,000 children, to replace two condemned schools in the neighbourhood. The area of the site is 5,300 square yards.

DUDLEY.—The Town Council have decided to apply for a loan of £1,250 for extensions to the Training College.

DUNBAR.—The congregation of the Parish Church have decided to build a new church hall and offices at Abbeylands. The cost will amount to £2,000.

EBBW VALE.—Mr. H. Waters' plans for a new drill hall have been approved, subject to certain minor alterations, by the War Office.

FLINTSHIRE.—The Flintshire Education Committee are about to undertake the erection of several new schools in the county. At Greenfield (Holywell) a new mixed school is to be built, to accommodate 350 children, and to replace the present old and inconvenient Bryncelyn National School. The site is near Greenfield Hall. The Holywell Rural District Council plans have been received and passed for the erection of a new school at Northop Hall to replace the school which was recently burned down. A new school is also to be erected at Saltney, at a cost of £3,000, and another at Shotton (in the parish of Hawarden) at a cost of £6,000.

GLASGOW.—The Municipal Buildings Committee of the Corporation have under consideration two schemes prepared by Messrs. Douglas, Hunter, and Whitson for reconstructing the second floor of the Municipal Buildings, one to cost £3,000 and the other about £4,200.

GRANGEMOUTH.—A new church is to be built here at a cost of about £5,000. Messrs. Wilson and Tait, of Grangemouth, are the architects.

GREYSTONES.—The completed church of Our Lady of the Rosary was opened on Sunday. The chancel, transepts, and one bay of the nave were erected in 1903, and the present addition completes the nave, now 80 feet long. Messrs. W. H. Byrne and Sons, of Dublin, are the architects, and Mr. Kinlan was the contractor.

HARROGATE.—A L.G. Board enquiry has been held respecting an application by the Town Council for a loan of £1,700, for extensions to the municipal offices.

HECKMONDWIKE.—The U.D. Council have passed plans for the erection of four almshouses, to be built and endowed by Mr. S. and Miss Smithson, at a cost of £3,000.

ILFORD.—The U.D. Council are considering draft schemes for the erection of a central library in Balfour Road, at an estimated cost of £8,000.

KETTERING.—A fund has been started for erecting a permanent building in place of the temporary iron church of All Saints in William Street. About £600 has already been collected.

LLANDUDNO.—A new gallery is proposed to be erected in the Town Hall, at a cost of £316.

LONDON.—The Trevor estate at Knightsbridge having been sold to Mr. J. C. Humphreys, it is anticipated that considerable rebuilding will take place on the estate to bring the houses up to the standard for the important residential position they occupy. A new road is contemplated from Knightsbridge to Brompton Road. Trevor Square will, however, be maintained.

LOUGHBOROUGH.—Funds are being collected for the erection of a church in the newly formed district of St. Peter's. About £2,440 has already been obtained.

NEATH.—Mr. J. Cook Rees, of Neath, has been appointed, by the Board of Guardians, architect for the new infirmary buildings.

NEWTON ABBOT.—The U.D. Council have approved a scheme for a secondary school for 200 students, at an estimated cost of £7,000 or £8,000.

NORWOOD.—A new secondary school for 450 boys is to be erected at Craster Road.

NOTTINGHAM.—The Baths Committee are contemplating the provision of more washing baths at the Victoria and Radford baths. They are also considering the provision of baths for the Meadows district.

ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

NOTTINGHAM.—The Public Libraries Committee are considering the necessity of erecting a more extensive central library. The accommodation in the present building in Sherwood Street, forming part of the University College buildings, is quite inadequate.

PURLEY.—It has been decided by the Croydon County Council to proceed with the scheme for the proposed reservoir at Russell Hill, which is estimated to cost £91,000.

RADCLIFFE.—In consequence of a communication received from the Local Government Board, the Radcliffe Council has decided to delete from the new Town Hall scheme the section intended for a police court and magistrates' rooms, the Board contending that such a building should be provided by the County Council. This will reduce the cost of the Town Hall by £3,000, making it about £12,000.

RADCLIFFE.—A new footbridge across the river in the Cawdaw district is proposed at a cost of £500. A Local Government Board enquiry has been held.

STAND.—The County Secondary School for the townships of Radcliffe, Whitefield, and Prestwich is to be built here at a cost of £21,000.

WANSTEAD.—Mr. Carnegie has offered to give £4,000 for the building and furnishing of a public library here, subject to the provision of a site and the raising of a penny rate by the District Council for the maintenance.

WESTCLIFF-ON-SEA.—Messrs. Hoare and Wheeler, of London, have submitted a design for the new Church of St. Saviour, estimated to cost £10,000 in all and arranged to seat 900 people. Efforts are being made to raise the money required to proceed with the nave and transepts—about £6,000 to £7,000.

WESTMINSTER.—A committee, on which the Duke of Norfolk has consented to act, is being formed to raise funds for the provision of an organ of adequate size in the Roman Catholic Cathedral. The cost is estimated at £10,000.

WINDERMERE.—The U.D. Council has adopted a scheme for the improvement of Bowness Bay, to cost about £10,000. They are also applying for a loan of £3,000 for further sewerage work.

WORCESTER.—As a memorial to the late Rev. H. H. Woodward, precentor of the cathedral, the choir school is to be rebuilt at a cost of between £3,000 and £4,000.

YARMOUTH.—Plans have been approved for the following:—Children's ward, hospital, for Hospital Trustees; alterations, Selby Place, Messrs. Davy and Sons; bungalow, Elm Grove Road, Mr. A. Gunns; rebuilding store, South Quay, Messrs. J. and W. Stuart; shop front, 66, Middlegate Street, Mr. W. Benjafield; additions to fishing premises, Charles Street, Mr. H. Sutton; shop front, 37, Regent Road, Mr. G. H. Gowing.

YELVERTON.—Sir Charles Nicholson, of London, has submitted his design for the new church to accommodate 350 persons, at a cost of £4,500. Of Gothic design, and built of local Hamhill stone, with Doulton stone and granite facings, the proposed new church would measure 100 ft. by 45 ft., with a chancel, nave, two isles, large vestries and a tower at the east end of the north isle of some 65 ft. A gable roof is provided for, and whilst the architect has arranged for doors at the west end and east end, a large north porch would form the principal entrance.

Mr. John B. Thorp, who worked out and built the excellent representations of "Old London" which were so popular last year at the White City, having been seen by nearly half a million people, including Her Majesty the Queen and many members of the Royal Family, has made arrangements with the Golden West Exhibition Committee to exhibit the work at Earl's Court. "Old London" has been opened in the "Midway," and is again proving a great attraction. Doubtless many of our readers will be glad to have another opportunity of seeing this interesting work.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himself of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable; and it must be understood that both question and reply will, as a rule, be published in these columns.

Gordon's Formula for Struts.

KIDDERMINSTER.—"H." writes: "Kindly state whether, in Gordon's formula for stanchions and posts (see below) W=safe load, or the breaking load in lbs. per square inch of area of cross section of pillar."

In Gordon's formula, the resulting load will be a safe load or breaking load, according as f is taken as the safe or the breaking stress. See also my replies on this formula in THE BUILDERS' JOURNAL of February 17th and April 14th, 1909.

The best form of the formula is

$$W=\frac{f\,A}{1+\frac{l^2}{r^2}}$$

In the query it is given as $W=\frac{f}{1+\frac{l^2\div r^2}{A}}$;

this is incorrect, but is probably a slip.

A.

Dark Grey Cement.

KILMALLOCK.—T. A. W. writes: "Please state the best method of getting a permanent dark grey or blue grey colour in external cementing. Would fine clean breeze be objectionable?"

The substitution of smith's ashes for sand in cement mortar will give a permanent dark grey colour. There would probably be no harm in the use of fine breeze for a similar purpose. A bluish colour may be obtained by a mixture of three parts of fine iron scale, three of cement, and two of clean river sand.

G.

Treating Laundry Liquid Waste.

LONDON, E.C.—H. P. E. writes: "Is there any method of treating laundry waste so as to render it free from foreign matter?"

Filtration will absorb some of the suds and coarser dirt, but you may need five beds at different levels, and these occupy more space than most laundries can spare or buy. Chemical treatment is too complex for reply here, and the methods are said to be costly and not complete. A complete analysis of the hardness of the water and of the soaps, starches, and glazes used is required in each case. Time and temperature are also factors, and the waste liquid has to be heated or cooled if success is to be attained. The chemist to a laundry association should be able to advise you in detail. INGENIOR.

Institute of Sanitary Engineers' Examinations.

Our correspondent "F. L.," who asks for information on this subject, should apply for full particulars as to the examinations to the Secretary of the Institute of Sanitary Engineers, 120 and 122, Victoria Street, London, S.W. The prospectus, which will be sent to him on application, contains full information as to subjects of examination, dates and places at which examinations are held for the two classes of membership, but if he also encloses 7d., he will be sent, in addition, a further pamphlet containing fuller information and advice, and also a copy of a set of examination papers recently set. Each examination extends over two days, and both are held in May and November each year, in London and certain provincial centres. Our correspondent might also be interested to obtain particulars of the Royal Sanitary Institute, for which he should write to the Secretary. Examinations are held for certificates for local surveyors and inspectors of nuisances. B. AND B.

Buildings to Measure in the Croydon District.

SOUTH CROYDON.—NEMO writes: "Could you kindly mention, as suitable for measuring, a few buildings, preferable Renaissance or Tudor, within about 20 miles of Croydon?"

Presumably London is to be excluded, otherwise many examples could of course be found there. Hampton Court Palace will provide a wealth of work, both Renaissance and Tudor, and permission to sketch and measure is readily obtained. Other buildings within the radius are the Whitgift Hospital at Croydon, Bromley College (entrance possibly by Wren), Eltham Palace, Eltham Golf Clubhouse (Wren; fine staircase), Pendell House, Bletchingly (attributed to Inigo Jones), and Ightham Moat. There are several large mansions within the district, *e.g.*: Knole (Sevenoaks), and Foot's Cray Place; but permission to measure is usually refused.

G.

Ware's "Complete Body of Architecture."

In reply to "S," Mr. B. T. Batsford, 94, High Holborn, to whom the query was submitted, states that Ware's "Complete Body of Architecture" is not worth more than 15s. or £1, according to condition, and is not very rare.

Space and Weight of Water.

Mr. Herbert A. Mitchell, P.A.S.I., Winchester is thanked for pointing out that in our issue for May 5th, p. 434, under the heading "Capacity of Cyclinder," the statement that one pound weight of water occupies 26 2-3rds cub. ins. should read 27 2-3rds cub. ins. (i.e., 1-10th of 276 cub. ins.), as there are 10lbs. to 1 gallon of 276 cub. inches.

Buildings to Sketch at Oxford.

In reply to several correspondents who desire information with reference to the buildings at Oxford that are best worth sketching, a contributor supplies the following list: From the abundance of material for the study of Renaissance architecture in Oxford, the following selection (arranged approximately in progressive chronological order) may be made: Wadham College Quad, with interiors of hall and chapel (1613); Archbishop Laud's Convocation House (1630); St. John's College back quad and garden front (1631-5); porch of St. Mary's Church (1637); Dean Duppa's organ case in the cathedral (1630); Lincoln College Chapel; arch in Botanical Gardens (Nicholas Stone), Ashmolean Museum entrance front; Sheldonian Theatre (Wren, 1668); Trinity College Chapel (Wren and Aldrich, 1691-4); Queen's College Library (Wren, 1693-6); All Saints' Church (Aldrich, 1700); Peckwater Quad at Christ Church (Aldrich, 1705); Clarendon Building (Vanbrugh and Hawksmoor, 1710); Queen's College, street front and quadrangle (Hawksmoor, 1713-30); Radcliffe Camera (Gibbs, 1749). The two latter are the most complete classic buildings in Oxford. Permission to sketch during vacation time can generally be obtained by application to the proper authorities—for the various colleges usually their respective presidents. Facilities for measuring are less readily granted, and it is useful to know when buildings are likely to be under scaffolding. At present Wren's Tom Tower at Christchurch is in this condition (hardly classic, though!), and it is probable that the garden front of St. John's—one of the finest things in Oxford—will shortly be so Details of fittings—such as the interiors of libraries, halls, and chapels, which can be measured without special preparations, are, of course, less troublesome. Trinity Chapel and Queen's Library may be quoted as examples. Outside Oxford, Abington should be visited, and the Town Hall and several interesting almshouses around the churchyard and in Ock Street seen; while a visit should also be paid to Blenheim Palace, at Woodstock, Sir John Vanbrugh's most colossal work. G.

R.I.B.A. Examinations.

MANCHESTER.—S. writes to the effect that students preparing for the R.I.B.A. Final Examination would be glad of guidance as to the requirements under the revised regulations.

We hope to be able to publish, in an early issue, an article in which this difficulty will be met.

Stresses on Domes.

GLASGOW.—READER writes: "Please explain how to calculate, by the graphic method, the stresses in a semicircular dome."

The graphic method is not applicable to stresses on a dome. Tarn's "Mechanic of Architecture," which can probably be seen in a public library, contains a chapter on domes. HENRY ADAMS.

Permanent Green Stain.

HALIFAX.—PROCTOR asks: "Please recommend a really permanent green stain for use in staining pitch-pine for internal woodwork."

"Matsine," manufactured by Messrs. Mander Brothers, of Wolverhampton, can be recommended by the writer. When the green colour of this is applied to pitch-pine, it yields some remarkable effects of a peacock blue, or green shades varying and changing from the position in which the work is viewed. No doubt the firm would be glad to send you a sample if you would apply to them. The blue "Matsine" also produces artistic and novel effects. J.

Length of Hip Rafter.

BRIDGEND.—A. J. J. writes: "A building 18ft. wide has its front wall at right angles to its side walls, which are respectively 36ft. and 46ft. long. The pitch of the roof is 45 degrees, and it is hipped at the ends at pitch of 60 degrees. Draw to ⅛ scale the outline plan of the roof, and determine the lengths of the hip rafters."

As the sides are at 45 degrees pitch, the height of the ridge will be equal to half the span. Then, as the ends are at 60 degrees pitch, this angle set off from face of building to cut the ridge will be the plan of hip. A right angle set up on plan from junction of hip and ridge, and cut off at a length equal to half span, will, if joined to angle of building, give true length of hip rafter. In answer to a further question, for information on designing cottage hospitals, see Sir Henry Burdett's "Cottage Hospitals" (10s. 6d.), Worcester and Atkinson's "Small Hospitals" (5s. 6d.), Sir Douglas Galton's "Healthy Hospitals" (10s. 6d.), and Mark's "Principles of Planning" (8s. 6d. net). HENRY ADAMS.

Calculations for Steel Girder.

EDINBURGH.—"S" writes: "A steel girder is required to span an opening of 30ft., and to carry a distributed load of 30 tons. The deflection at centre is not to exceed one-thousandth of the span, and working stress in flange is limited to six tons per square inch. Required, the necessary depth of girder and (neglecting web) flange area."

The deflection at the centre of a uniformly loaded girder of span L carrying A weight of W tons is given by

$$8=\frac{5\,WL^3}{384\,EI} \quad .. \quad .. \quad .. \quad (1)$$

Where E = Young Modulus in tons per sq. in.
I = Moment of Inertia in inch units.

If f is the max. stress in tons per sq. in., d is the distance from the neutral axis to the extreme fibre and M the max. bending moment.

$$f=\frac{M\,d}{I}=\frac{WL}{8}\cdot\frac{d}{I} \quad .. \quad .. \quad .. \quad (2$$

Now if deflection $= \frac{1}{1000}$ span, combining equations (1) and (2)

$$\frac{L}{1000}=\frac{5\,WL^3}{384\,E\,I}=\frac{5}{48}\cdot\left(\frac{W\,L}{8\,I}\right)\cdot\frac{L^2}{E}$$

$$=\frac{5}{48}\cdot\frac{f}{d}\cdot\frac{L^2}{E}$$

$$\therefore d=\frac{5000\,.\,f\,.\,L}{48\,.\,E}$$

If $f=6$ tons per sq. in. $L=30'=360''$ and $E=13{,}000$

$$d=\frac{5000\times 6\times 360}{48\times 13000}=17\cdot 3 \text{ in.};$$

but d is half the depth of the girder, assuming the section t be symmetrical about the neutral axis ∴ depth of girder $=2\,d=34\cdot 6$ in. say 3 ft. To get the necessary section assume breadth of flange $=\frac{\text{depth}}{3}-12''$; nett breadth allowing for 2 $\frac{7}{8}''$ rivets $=(12-2\cdot\frac{7}{8})=10\cdot 25$. Then section modulus neglecting web = area of flange × depth,

$$=10\cdot 25\,t\times 36, \text{where } t=\text{thickness of flange.}$$

$$\therefore B\,.\,\frac{M}{f}=\frac{W\,L}{8\,f}=10\cdot 25\times t\times 36$$

$$\therefore 10.25\times t\times 36=\frac{30\times 360}{8\times 6}$$

$$t=\frac{30\times 360}{36\times 10\cdot 25\times 8\times 6}$$

$$=\tfrac{5}{8} \text{ in. nearly.}$$

If nett flange area is required this is given by

$$A=\frac{WL}{8\,f\,D}=\frac{30\times 360}{8\times 6\times 36}=\frac{300}{48}=6\cdot 25 \text{ sq. in.}$$

A.

GLASGOW ARCHITECTURAL CRAFTSMEN'S SOCIETY.

The annual report, 1908-9, of the Architectural Craftsmen's Society of the Glasgow and West of Scotland Technical College shows that during the session seven new members were admitted, six resigned, and seventeen were struck off the roll; the present membership being 118, against 134 in the previous year. During the session, the following addresses or lectures have been heard:—President's opening address, Mr. J. Campbell Reid, A.R.I.B.A.; "The Preservation of Our Ancient Buildings," Sir John Stirling Maxwell; "An Architectural Tour in France," Prof. C. Gourlay, B.Sc., A.R.I.B.A.; "The Construction and Working of a Septic Tank and Circular Bacterial Percolating Filters," Mr. Thomas Davis; "The Construction and Arrangement of Laboratory Fittings," Mr. Colin Sinclair, M.A.; "Contracts and Contracting," Mr. Robert Murdock, F.S.I.; "Reinforced Concrete," Mr. F. A. MacDonald; "The Personal Factors in Italian Renaissance Architecture," Vernon Constable, A.R.I.B.A.; "A Tour through Somersetshire," Mr. T. G. Gilmour; "A Portland Stone Building," Mr. Thomas McCrae; Discussion on Reinforced Concrete Construction, opened by Mr. Vernon Constable. Visits were paid to the following buildings, the names of whose architects are given in parentheses:—Additions to Clyde Trust Buildings (John Burnet and Son); New Mitchell Library Buildings (W. B. Whitie, F.R.I.B.A.); Royal Infirmary Buildings (James Millar, A.R.S.A.); New Liberal Club Building (Campbell Douglas and A. N. Paterson); Additions to Merchants' House (John Burnet and Son); Northern Assurance Company's Buildings (J. A. Campbell, F.R.I.B.A.). The joint secretaries are Mr. John Wilson and Mr. Alexander Davidson.

In describing the Letchworth cottages (Mr. Edmund A. Fermaud, architect) illustrated on p. 13, in our issue for July 7th, it was stated, by a regrettable slip of the pen, that they were placed first by the committee of assessors at the last Letchworth Cottage Exhibition. They won a second prize, the design by Mr. W. J. Lewton, of Reading, being placed first.

Buildings in Progress and Completed.

AYR.—A new roller-skating pavilion has been opened here. It is constructed of white fibrous plaster slabs, after the manner of exhibition buildings, and comprises in addition to the rink space of 16,000 square feet, with its maple floor, tea rooms, rink buffet, roof tea garden, smoking lounge, promenade and garage. The architect was Mr. J. Campbell Reid, A.R.I.B.A., of Glasgow, and the contractors were Messrs. J. and D. Meikle, of Ayr.

BIRMINGHAM.—The tender of Messrs. Waring and White, London, at £128,744, has been accepted by the City Council for the superstructure of the Council House extension.

BLYTH.—A new manse for the Waterloo Road Presbyterian congregation is in course of erection at a cost of £1,200. Mr. John Goulding, of Blyth, is the architect, and Messrs. J. and E. Simpson are the contractors.

BOURNEMOUTH.—Extensive alterations and improvements are being carried out at the Shaftesbury Hall, St. Peter's Road, from the designs of Messrs. Creake, Gifford and Oakley. The cost will be £1,600. Messrs. Jenkins and Sons, Ltd., are the contractors, and the electric light is being installed by Messrs. Chadwick and Roberts.

CARLTON-IN-CLEVELAND.—Mr. Temple Moore, of London, has submitted sketch designs for the proposed new church, which is to cost £1,000.

CARMARTHEN.—The Shirehall has been reopened after alterations and decorations from the designs of Mr. W. Vincent Morgan (County Architect). The contractors were Messrs. B. Howell and Son, Llanelly.

CLAYGATE. — A new Swedenborgian Church has been erected here to seat 180 people. The stained glass and mosaic was designed and detailed by the architect, and made by Messrs. George Wragge, Ltd., and Rust's Vitreous Mosaic Co. respectively. The buildings are heated by open fireplaces, and there are also some radiators. The architect was Mr. Ernest Edward Trobridge, of 87, Cheverton Road, London, N., and the contractor was Mr. Higby, Claygate.

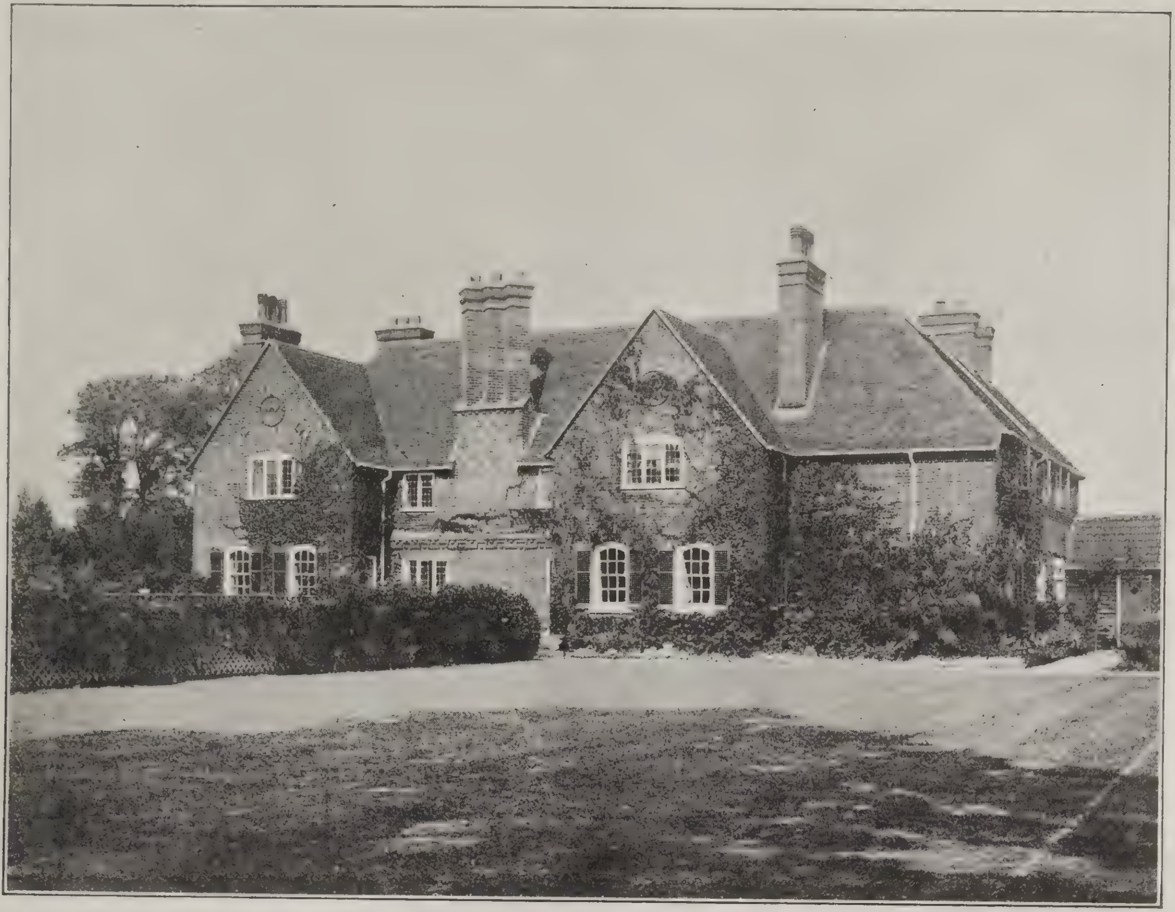
CRICKLEWOOD.—The foundation stone of St. Michael's Church has been laid. The new building will provide accommodation for 754 persons. The principal dimensions are: Length 152ft. 10½ins., width 60ft., height to ridge 55ft., and the chapel will be 50ft. long, and 15ft. wide. Mr. J. S. Alder is the architect, and Mr. H. Knight the builder.

DEWSBURY.—A new frontage, designed by Messrs. Holton and Fox, of Dewsbury, is being erected to the Hippodrome. The contractors for the masonry and brickwork are Messrs. Humphries and Green, of Dewsbury; the joinery work is being done by Messrs. Clegg Bros., of Westtown; Mr. J. E. Talbot is fitting up the lavatories, improving the gas fittings, and doing the necessary plumber's work; Messrs. Maclean, of Leeds, are doing the concrete and laying mosaic pavements to main entrances; Mr. Bottomley is providing the patent glazing for the verandah; Mr. Hodgson is responsible for the plastering; Messrs. A. Hirst and Son, Ltd., Victoria Road, are putting in the electric lights; and the decorations, inside and out, have been entrusted to Mr. Ned Ramsden, of Halifax Road.

DONYATT.—The Somerset County Council has accepted the tender of Mr. R. G. Spiller, Chard, at £519, for rebuilding Donyatt Bridge.

EDINBURGH.—The Royal Institution having found new quarters at the New Art School in Lauriston, the Royal Institution building is being reconstructed to fit it for the use of the Royal Scottish Academy. Mr. W. T. Oldrieve, F.R.I.B.A., F.S.A., of H.M. Office of Works, Scotland, is the architect.

GARNDIFFAITH.—A new institute, containing a public hall to seat 600, a billiard-



FOURACRE, WINCHFIELD, HANTS. GARDEN FRONT. ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

This house is built with red sand-faced bricks and tile roof. The woodwork generally is painted white, with the exception of the doors and shutters, which are green. The pattern work on the gables and between the wings is executed in plain projecting bricks, and the diaper work on the chimneys with flare ends.

room for 3 tables, reading-room, library, coffee bar, and caretaker's rooms, has been erected at a cost of £1,800, from the designs of Mr. W. Beddoe Rees, of Cardiff. Messrs. Bailey Bros., Pontypool, were the builders.

GREAT HOLLAND.—A new village hall is being erected here at a cost of £850. Mr. W. Hayne is the architect, and Mr. A. E. Farr the builder.

HATCH BEAUCHAMP.—The Somerset County Council have accepted the tender of Messrs. H. Pittard and Son, Langport, at £372, for rebuilding Bottle Bridge.

IRVINE.—The extensions of the Cunningham Combination Poorhouse have been completed. The new buildings include a board room, governor's office, and probationary wards, and have cost £5,000. Mr. Hay was the architect

LITTLEHAMPTON. — The tender of Messrs. Linfield and Sons at £1,446 has been accepted for the new pavilion and shelter.

LONDON.—H.M. the King laid the foundation stone, on Thursday last, of the Imperial College of Science and Technology buildings, at South Kensington, on a site adjoining the Royal College of Music. The new buildings, designed by Sir Aston Webb, R.A., will house the mining, metallurgical, geological, and engineering departments of the Imperial College.

LONDON. — The County Council are about to rebuild the School of Photo Engraving and Lithography, Bolt Court, Fleet Street, at a cost of £15,000.

NORTHAMPTON.—A roller-skating rink has been erected at the George Hotel. The floor surface is 110ft. by 53ft., and there is a promenade bay 52ft. by 42ft. Mr. E. F. Goulding was the architect, and Mr. A. M. Dunham the contractor.

NOTTINGHAM.—The foundation stones of the Albert Hall Institute in Great Hall Street, Derby Road, have been laid. The building is designed in the Old English style of architecture with half timber work, the remainder being done in buff bricks. On the lower floor there are to be a gymnasium, a billiard-room, buffet, reading-room, and kitchen, this floor being designed exclusively for the use of the men. On the first floor is to be a hall, capable of seating about 600, together with two or three offices, for mission work. On the middle floor there will be a suite of four rooms for the sisters of the mission, and on the second floor a large church parlour and five other rooms of various sizes, to be used for church meetings of all kinds. On the top there are a hall, 45ft. by 30ft., and eight small rooms, to be utilised for the girls' social work. The institute is of fireproof construction throughout, and is estimated to cost nearly £9,000, exclusive of furnishing. Mr. A. E. Lambert is the architect.

PARTICK.—A new Congregational church is being erected here from the designs of Mr. George Simpson, Glasgow. The church is being built of red sandstone, and will accommodate 600 persons. There is also a hall to hold 250. The cost will be £3,000.

PELTON.—A new institute has been erected by the owners of the Pelton Colliery for their workmen. Mr. J. T. Lee, F.R.I.B.A., is the architect, and a drawing of the building is exhibited at the Royal Academy.

PERTH.—The foundation stone of the new City Hall has been laid by Lord Provost Cuthbert. Mr. C. E. Clifford, of Glasgow, is the architect.

PORTADOWN (IRELAND).—New National schools have been opened here. Mr. J. W. Walby was the architect, and the builders were Messrs. Collen Brothers. The total cost was £2,400.

PORT-GLASGOW. — The improvement scheme in the Bay Area, to cost upwards of £80,000 has been commenced by the demolition of the old properties. Messrs. P. McBride and Co., contractors, of Port-Glasgow, have secured the contracts for the digger, mason, brick, slater, and joiner works.

RAWDON.—A new R.C. church for the districts of Rawdon, Yeadon, and Guiseley, has been erected here. Mr. E. Simpson, of Bradford, was the architect.

RETFORD.—The foundation stone of a new dispensary in connection with Retford Hospital was laid on the 30th ult. The building, in the Gothic style, has been designed by Mr. William Southall, and the contract has been let to Messrs. Thomas Hopkinson and Son, of Retford.

SANDYFORD.—A new Wesleyan chapel for 300 persons is being erected at a cost of £2,000. Mr. Henry Dain, of Tunstall, is the architect, and Mr. Paul Pemberton, Tunstall, is the builder.

SCHOLES.—The Barwick Parish Council offices have been opened. The premises provide a council room 28ft. by 18ft., with living accommodation for the assistant overseer, at a cost of £650. Mr. H. M. Chippindale, of Scholes, was the architect, and Mr. G. Wilson, of Whitkirk, the builder.

SCISSETT.—A new parish room is being erected here at a cost, including land, of £1,200. Messrs. John Kirk and Sons, of Huddersfield, are the architects; and contracts have been let to the following:—Mason and bricklayers' work, Messrs. George Hinchliff and Son, Clayton West; joiners' work, Messrs. Issac Wray and Son, Clayton West; plasterers' work, Mr. W. S. Needham, Clayton West; plumbers' work, Messrs. George Garton and Son, Huddersfield; painters' work, Mr. William Jubb, Denby Dale; slaters' work, Mr. W. E. Jowett, Huddersfield; concreters' work, Mr. John Cooke, Huddersfield; and heating apparatus work by Messrs. T. A. Heaps and Co., Ltd., Huddersfield.

SELBY.—A new oil and cake mill for Messrs. Joseph Watson and Sons, Ltd., soap manufacturers, of Leeds, is in course of erection at an estimated cast of £100,000. Sir Alfred Gelder, F.R.I.B.A., of Hull, is the architect.

SOUTHAMPTON.—A new wing is being added to the Western District Council Schools to provide additional accommodation for 240 boys, 240 girls, and 120 infants. The cost is estimated at £6,500. The plans have been prepared by the Borough Engineer.

SUNDERLAND.—The west end branch library, erected at the cost of Mr. Carnegie, has been opened. Mr. Hedley was the architect.

SUTTON-IN-ASHFIELD.—The contract for the erection of the Council's new school at Sutton-in-Ashfield has been let to Messrs. T. Fish and Sons, of Nottingham, for £5,738 12s. The school is to provide accommodation for 200 scholars in the higher standards, and 120 in the higher elementary. Provision will be made for a cookery room and laboratory, and a workshop for manual instruction.

SWANSEA.—A large block of shops and offices is to be erected at the corner of College and Castle Streets for Messrs. James and Gustavus. Mr. Sydney Crocker, of Cardigan Chambers, Swansea, is the architect.

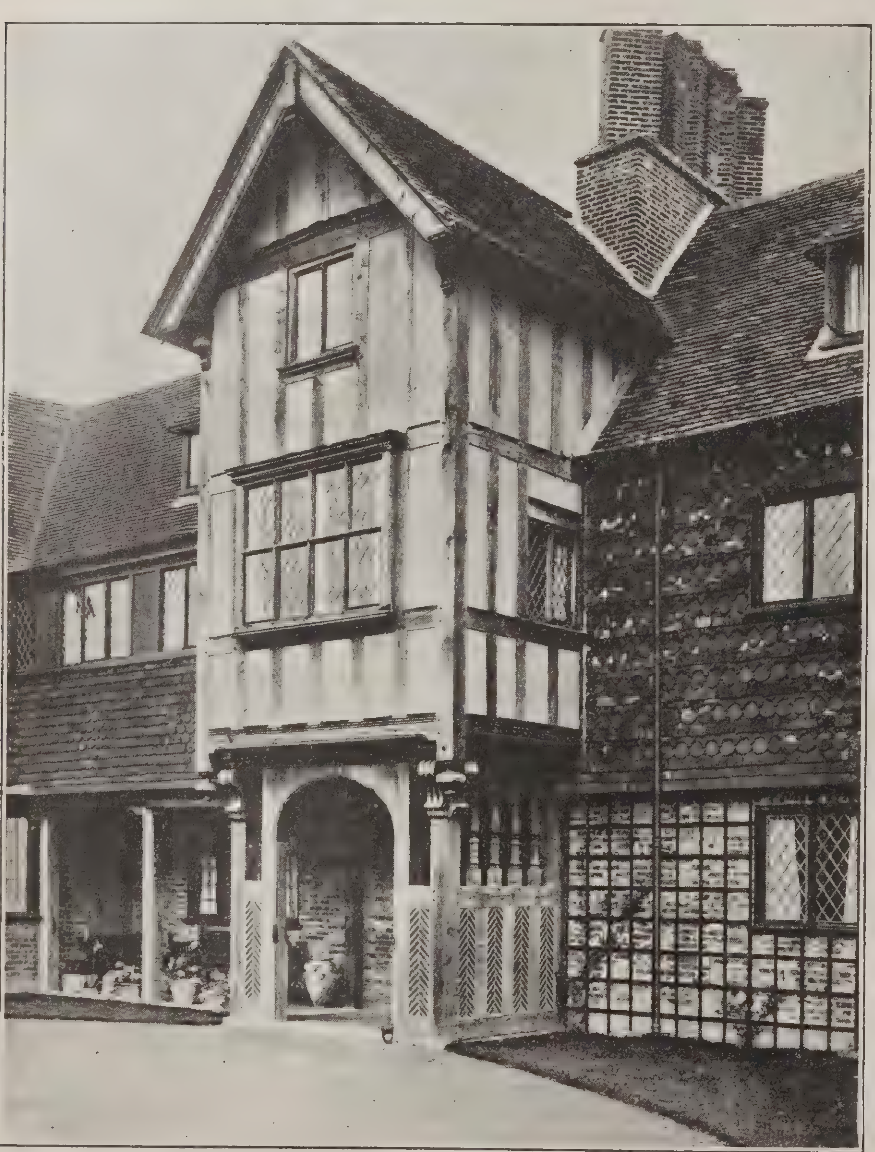
TAYPORT.—A new hall, accommodating 200 people, in connection with the Queen Street U.F. Church, has been erected. Mr. Alex. Lickley, of Bank Street, Dundee, is the architect, and the following were the contractors:—Mason, Mr. W. Kemp; joiner, Mr. W. Dowie; plasterer, Mr. C. Ferrie; painter, Mr. G. Harley—all of Tayport; plumbers, Messrs. Murray and Son, Broughty Ferry; slater, Messrs. A. Hogg and Son, Broughty Ferry; heating engineers, Messrs. James Fyffe and Son, Dundee.

TIDWORTH.—The new Garrison Theatre has been opened. The new building provides seating accommodation for 1,250 persons, and is a plain structure harmonising with the surrounding barrack buildings. Messrs. Billett and Musselwhite were the contractors, and the cost was more than £4,000.

WOKING.—The London and South Western Railway Orphanage buildings have been completed. They are designed to house 150 children, and are faced with red brick and stone dressings. Mr. W. E. Trevena, of Farnborough, was the architect, and Mr. E. C. Hughes, of Wokingham, the builder. The total cost, including equipment, amounts to £24,000.

YEALMPTON. — A new Wesleyan Methodist Chapel and school is being erected at a cost of £1,090. Mr. F. A. Wiblin, of Plymouth, is the architect, and Messrs. Prowse and Son, of Ermington, are the contractors.

YORK.—A new Wesleyan Methodist Sunday School is being erected in Acomb Road, to accommodate from 300 to 400 scholars. The cost will be about £3,200. Mr. T. Monkman is the architect, and the following contracts have been let:—Brickwork, Messrs. F. Shepherd and Son; woodwork, Mr. G. Mansfield; slating, Messrs. J. Dodgson and Son; plastering, Messrs. Young and Sons; plumbing, etc., Mr. J. H. Shouksmith; painting, Mr. R. Pearson, all of York; hot water engineers, Messrs. W. Richardson and Co., Darlington.



UPTON GREY, HANTS. ENTRANCE. ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

The porch and bay-window illustrated were built up with some old oak obtained from a barn that was pulled down, and it is of a rich brown colour.

CONTRACTORS' USE OF COAL: A SCIENTIFIC SYSTEM OF BUYING.

By a Contractor.

Coal is always an unsatisfactory thing for a contractor to buy, because there is no item for it in a bill of quantities. It nevertheless forms a very serious item in his yearly expenditure. The results of the scientific testing of materials generally are steadily coming to be regarded as the only intelligent basis of purchase.

Few contractors would buy Portland cement without being satisfied that it came up to the British standard specification, but so long as cement conforms to the British standard, it will satisfy the architect or engineer who is superintending the contract. Why not apply the system to coal?

Absence of a Standard for Coal.

With coal buying, however, there is no standard to which the quality of any particular sample can be referred for comparison. As coal is a natural and varying product, it is obvious that a fixed standard is impossible. It is, however, not only possible, but extremely simple and inexpensive to establish by tests the money value of any particular coal. At present the ordinary method of buying is to order a sample truck load. If the quality and price seem satisfactory to the individual buyer, he will place the order on the understanding, either expressed or implied, that further supplies shall be equal to the first truck load. He may even specify that the deliveries shall be from the same seam of the same colliery. He has, however, no assurance that he will continue to get coal as good as the first truck load. There remains the question as to how he shall test such deliveries.

The writer of this article, before going further, would make it clear that he is in no way an expert in coal, but is setting down his own experience in coal buying, with the record of actual purchases and the results obtained from them. He felt, on starting to buy coal for a large contract near London, that the time had come to be satisfied no longer with any particular coal because it was black, but to employ some simple and practical method by which a uniform amount of steam-raising power could be secured for every penny that was spent. The practice of paying for coal according to its steam-raising power, and not on the arbitrary price per ton asked by a coal merchant, is well established in the United States. It is also employed in England by large and regular users, such as electric generating stations and Government Departments. There is no reason, however, why any contractor who uses as much as 50 tons a week should not adopt the same methods, though in a form simpler than obtains with very large organisations.

Methods of Coal Analysis.

There are roughly two sorts of analyses of coal which can be taken. One gives the percentage of carbon, ash, hydrogen, nitrogen, oxygen, and sulphur. Such an analysis is largely of academic interest. Contractors do not want to know about hydrogen and nitrogen, but about steam-raising. As to sulphur, contractors' plant is rarely of a delicate character, nor is it generally too well maintained. An excess of sulphur in coal tends to produce corrosion of the fire-box, but with boilers of simple type this is not a serious matter. To take tests for sulphur, and to establish any scheme for reducing the price of any particular coal by reason of its excess of sulphur, brings in an unpractical element of complication. The quantity of sulphur, then, is neglected in the present consideration of the question.

UPTON GREY, HANTS. BAY ON GARDEN FRONT. ERNEST NEWTON, F.R.I.B.A., ARCHITECT

Everything of interest has been retained and repaired, but the house had fallen into a very bad state. Inside some fine oak panelling and a massive oak staircase have been preserved.

The other and more practical form of analysis gives the percentages of moisture and ash, and the evaporative power of the coal. The point to keep in view all the time is the contractors' use of coal, which is to boil water. The main feature to look for in every analysis is, therefore, evaporative power. This can be stated in three ways—(1) as calories, (2) in pounds of water evaporated by a pound of coal, and (3) in B.T.U. (British thermal units). All these three expressions of steam-raising capacity have a fixed relationship to each other, but British thermal units have been taken in this article as the most convenient for calculation, and the other two expressions are therefore omitted from the tables to appear later. Calories can readily be turned into B.T.U. by multiplying by 9 and dividing by 5.

The Cost of Carriage.

It must be clearly understood that the B.T.U. afforded by different classes of coal must be considered, not alone, but in relation to the prices of the different coals delivered at the site where the coal is to be used. The cheapest coal may well prove, by reason of its low efficiency, to be the most expensive in actual use. The point to which the coal has to be delivered is obviously of supreme importance. One colliery may produce a coal which gives 10 per cent. more in B.T.U. for the same price per ton at the pit's mouth, than the product of another colliery, but the higher cost of carriage of the superior coal may wipe out the advantage. All calculations, therefore, should be based on the price of the coal, including carriage to its place of use.

The Value of Tests.

The purpose of this article is to show the value of adjusting the purchase price of coal on a sliding scale according to its value in B.T.U., but even if the method (to be later described) is not adopted, tests are worth their cost, if only as enabling the consumer to check the varying quality of consignments of the same coal.

Ten Typical Tests.

Coal from 10 different collieries was tested. In each case, from 30 to 100 tons were purchased at the best prices that the respective merchants would quote, and these prices (which include delivery) will be shown in a table. In some cases the colliery issues copies of the analyst's certificate of the tests they have made on their coal. These are for two main reasons unsatisfactory. In three colliery certificates which are now before the writer, one is dated December, 1900, another September, 1903, and another June, 1904. It is obvious that the seams tested at those dates may have been worked out, and the coal now being produced may be from a better or worse seam. Moreover, these tests are sometimes taken on dry coal, i.e., on coal which has been artificially dried. Seeing that, as proved, the moisture of different coals varies between 10 per cent. and 18 per cent., and that the weight of coal which a contractor buys includes its moisture, and that the proportion of moisture greatly affects its steam-raising capacity, colliery certificates on analysis made in this artificial way need not be regarded very seriously.

In some cases the colliery certificates do the coal less than justice. In one series of tests on three actual deliveries, the B.T.U. averaged 12204, whereas the printed analysis issued by the colliery of the same coal showed only 11768. The discrepancies, however, are generally the other way.

For instance, the sample of coal first tested should have given on the basis of the colliery certificate 76 B.T.U. per penny of cost per ton, whereas on the test of an actual consignment it only yielded 66. In the case of sample B the disproportion was even greater, 72.5 as compared with 58.

It is clear that with coals of different price some common standard of value must be obtained, and the writer has adopted what seems a simple method, viz., of dividing the number of British thermal units by the number of British thermal units by the number of pence of cost per ten, the result being the number of units per penny.

English v. Scotch Coal.

The ascertained units as shown on the ten qualities examined vary from 58 to 74.5. In other words, if all coal purchased had been equal to the sample "J 1," a saving in cost of 22 per cent. would have been effected.

Sample K, however, was one sample out of four consignments from the same district —viz., Fifeshire—though not from the same colliery, and it is of course doubtful as to whether further consignments from K colliery would have yielded such a high steam-raising capacity. It is obvious, however, that these Scotch coals were of better value on the average (the price per ton being taken into consideration) than the average of the English coals marked A to H in the table, as they yielded an average on the four samples of 70.5 units per penny. This result, compared with coal B, shows a saving of about 18 per cent., and compared with B.T.U. 63 the average of English coals A to H a saving of 11 per cent. (The tables will appear with the concluding portion of the articles.)

It must be understood, however, that this comparison of English and Scotch coals with a verdict in favour of the Scotch product applies only to the prices charged for the particular deliveries and to the particular contract, which is on the Thames and is served by a convenient wharf. The conditions were therefore ideal for the economical transit of Scotch coal, which was entirely water-borne. Had the contract been only ten miles from the river, thus necessitating rail as well as water carriage, the extra cost of freight might have turned the scale in favour of English coal. By the same token a reduction in the price of one of the English coals had, as will presently be seen, the same effect.

Proportion of Slack and Hardness of Coal

There are two other general considerations to be taken into account in comparing English and Scotch steam coals. English steam coals are generally either handpicked or screened, and have very little slack or dust. Scotch coals are sometimes sold in London as they come from the colliery, and the percentage of slack is high.

Even if a Scotch coal starts from Scotland screened, the increased handling will produce a considerable amount of slack, even if the coal be hard, and if it be soft the amount will be excessive. In practice, slack gets wasted, and even if a high calorific value is secured from the large coal, it may well prove more economical to be content with a smaller result of B.T.U. per penny from a coal of which every ounce will be used in the furnaces and in using which waste is inappreciable. Further, some of the Scotch coals are markedly softer than some samples of good English coal, and give more trouble in stoking, with the result that firemen tend to use their fuel wastefully.

It is impossible to establish by tests the proportion of slack, and the buyer must therefore judge of this side of the question by his own or his colleagues' practical observations. (See a later paragraph.)

Moisture and Ash.

The percentages of moisture and ash are not of such importance in determining the choice of a coal as the yield in thermal units, but they should not be altogether disregarded. An excess either of moisture or ash, or of both, has the result of reducing the number of B.T.U. yielded, but the disadvantages produced by such excesses have been to a large extent discounted before the steam-raising value of the coal is established. It is nevertheless true. that if there is an undue excess of moisture, part of the steam-raising capacity of the coal is employed in driving off that moisture instead of in heating the boiler. With respect to ash, an excessive percentage not only means undue clinkering, but also that an excess of weight amounting in one case to more than 15 per cent. has to be carted about the contract. Moreover, so great an excess of ash means a very slaty coal, and firemen are likely to throw aside and waste lumps which are particularly slaty. In ordering coal which will be paid for on the result of analysis, it is therefore reasonable that the buyer should specify a maximum percentage both of moisture and ash, say 12 per cent. of moisture and 5 per cent. of ash, and penalise the coal merchants if these percentages prove to be higher on test. Suitable reductions per ton are 1d. per ton for every one per cent. above the maximum percentages fixed. No rule can, however, be laid down, as the fixing of maximums must depend on the normal percentages yielded by the coal ordinarily used in the district.

Slow v. Quick Burning Coal.

If a fire can be kept under perfect control, it is immaterial whether the coal burns slowly or quickly; the B.T.U.'s given by the coal are the sole consideration. Contractors' plant consisting of portable engines, cranes, locos, etc., perhaps scattered over a contract of large area, does not, however, get the supervision that boilers assembled under one roof can receive, nor do contractors' firemen give the necessary attention to damping down a fire either mechanically or by throwing ash or clinker if the fire is burning too furiously. Some Scotch steam coals burn more freely than do English, and an English coal yielding rather fewer B.T.U. may therefore prove to be more economical in use. Fast burning is often, however, due to the virtues of a coal (viz., low percentages of moisture and ash) rather than to its vices. If a coal is dry when bought, it will obviously burn faster than if wet.

Expensive v. Cheap Coal.

In theory it is immaterial whether an expensive or a cheap coal be purchased, providing the standard number of B.T.U. per penny per ton is maintained. In practice, however, a contractor will be wise to buy a coal of average price. To buy the cheapest means excessive percentage of ash or moisture. The most expensive are equally undesirable, for the following reasons: There is apt to be a considerable waste of coal on a builder's contract, particularly if the plant is spread over a fairly large area. Assuming that 5 or 10 per cent. of the bulk of the coal never gets into the firebox, it is better that a cheap coal should be wasted rather than an expensive one. The Welsh smokeless coals have a very high calorific value, but they are costly in London, and do not prove economical unless carefully used. It is unusual for a contractor to get into trouble through discharging black smoke, and the smokeless merit of Welsh coal need not generally be taken into account.

The Practical Man.

Questions of this kind need to be considered by the practical men on the works, and their opinion of the comparative value of different coals should be taken into account in conjunction with the results of tests. The casual opinions of crane drivers do not deserve too close attention, as their knowledge does not extend to the price paid, and consequently does not take into account the amount of steam raised per penny. The present writer in one case ordered two consignments of coal from the same district, one from the best seams and one from the poorest, the difference in price being 5s. 5d. per ton. The speed of burning was about the same in both cases; the yield of B.T.U. was higher by 3,500 in the case of the superior coal; the inferior coal produced five times the normal amount of ash, yet the crane driver reported the inferior coal to be the better of the two! Experiences of this kind create a feeling of some doubt as to the value of firemen's opinions. The opinion of the practical man is of peculiar value when considering as to which of two or three coals yielding the same number of B.T.U. per penny per ton shall in future be ordered. His report on proportion of slack, clean burning, absence or presence of undue clinkering, and general economy of use, will enable the buyer to come to a correct decision.

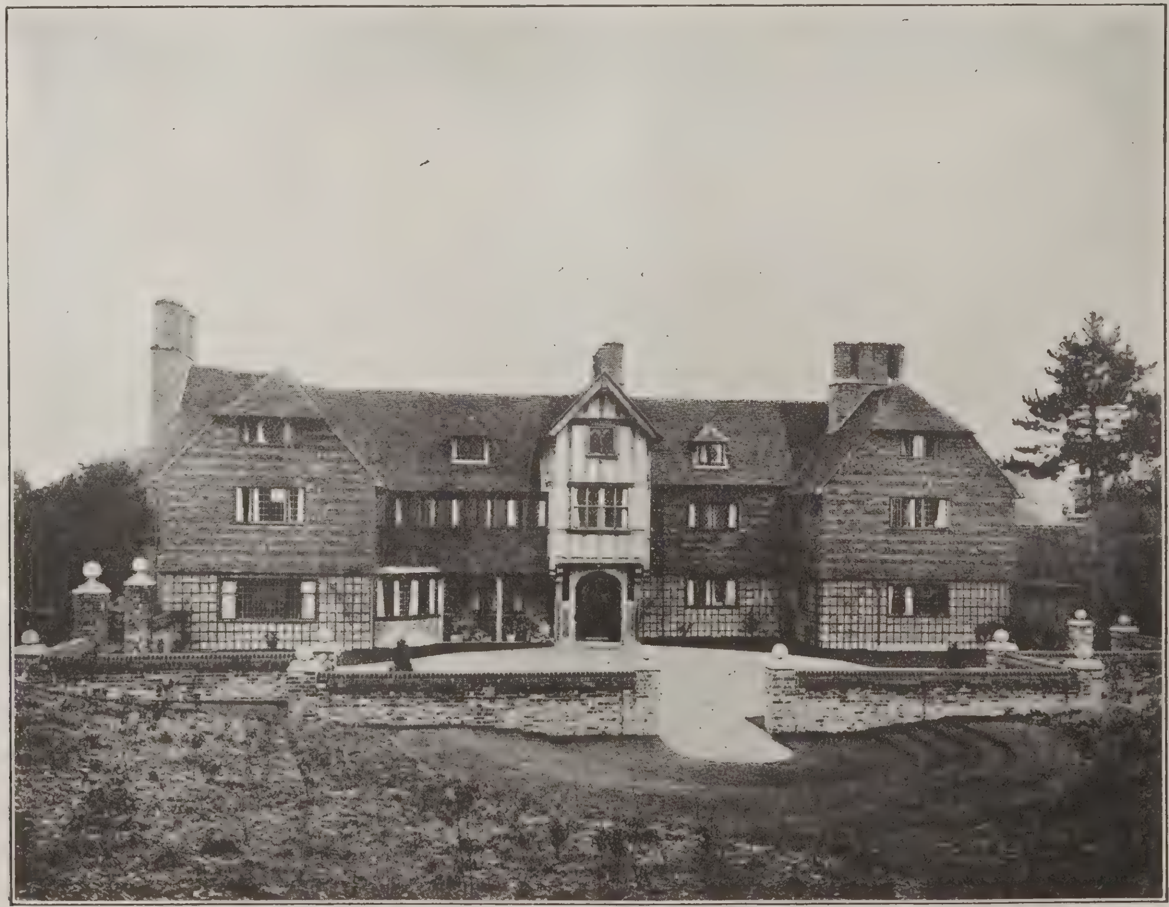
(To be concluded.)

PAINT AND ITS APPLICATION TO STRUCTURAL STEEL.*

By Gaston Depierres.

(Continued from page 527.)

Mr. Davidson said he should like to remark about the imperviousness of the paint, as he thought that this characteristic was perhaps as important as the quality of the pigment. Linseed oil in his opinion was by no means impervious to moisture. He had been informed that if a dried linseed oil film was put into water it would be found that in an hour and a half the water had assumed a somewhat cloudy appearance, and if the film was taken out and examined under the microscope, it would show distinct globules of water. There were other oils on



UPTON GREY, HANTS. GENERAL VIEW OF ENTRANCE FRONT. ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

This was an old farm-house, but very little of the original work remains except the chimneys and some portions of the half-timber work.

---

*Abstract of concluding portion of discussion on paper read by Mr. Gaston Depierres at a meeting of the Paint and Varnish Society. Other abstracts have appeared in the issue for April 7, p. 301, and that of June 2, p. 526

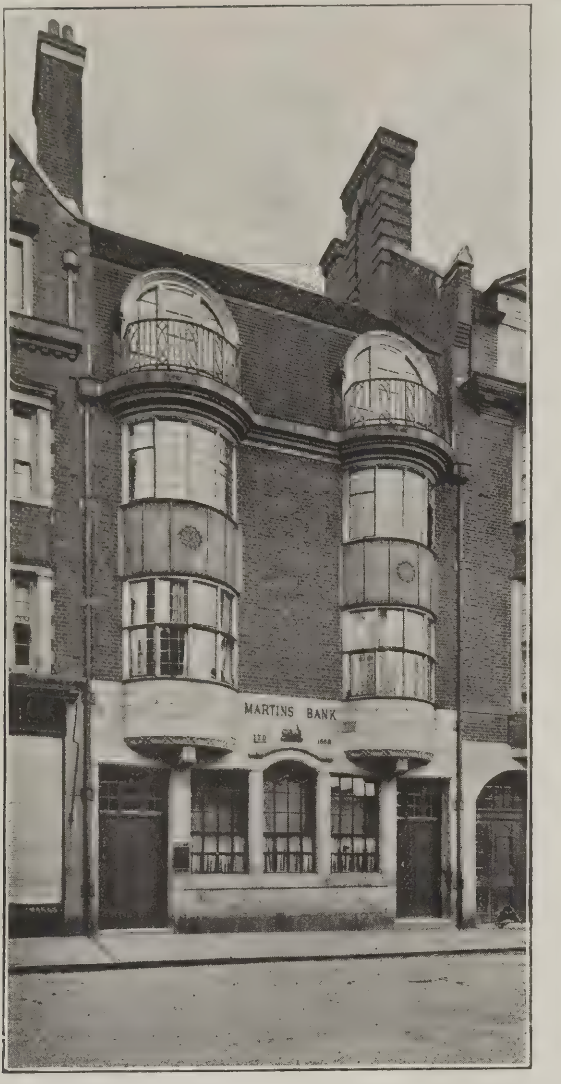


Photo: Architectural Review Photo Bureau

MARTIN'S BANK, BROMLEY, KENT. ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

The ground floor is faced with plain unpolished granite, the upper part with red bricks. The spaces between the bays are covered with cast lead; in the centre of each space is an enriched panel with monogram painted and gilded. The cornice is of wood, and the roofs are covered with dark red hand-made Wrotham tiles. Mr. Newton also designed the shop on the left-hand side of the bank, and supplied sketches for the front of the Bell Hotel on the right-hand side, but had no control over the latter work in detail.

the market which were capable, when properly used, of making a paint which would yield much better results for steel and iron than did linseed oil paints.

Mr. J. Russell Thornbery asked whether it was not a fact that red oxides would absorb moisture more rapidly than the harder oxides of iron and the magnetic oxides? Another point which occurred to him was that some suggestions were made by experts that were very difficult of being carried out in actual work. What had to be done was to find some means of applying a paint under practical conditions, and to use a paint of a suitable nature for the work. The suggestion that the paint should be kept in hot-water baths during application was not in his opinion practicable when one considered the conditions under which paints had often to be applied. With regard to painting during moisture and condensation forming on metal, he might mention a case which had come under his notice in that connection. A ship, having been painted, started on her voyage, and after getting into the Gulf Stream the whole of the paint simply slipped off. On careful examination as to the cause of this occurrence, it was found that the ship had been painted during a frost, the whole of the metal being covered with a coat of ice when the paint was applied, consequently it only needed a warmer temperature for the foundation to thaw, and the ship simply shed its coat. The conditions under which contract work was often executed made painting a very difficult undertaking, and the life of the paint manufacturer oftentimes a very sad one. Paints specially prepared for specific work were specified by engineers; the contracts were let and sub-let, and the painting was often pushed off to the last minute, so that it was impossible to expect a satisfactory job. But if anything went wrong it was the paintmaker who got the blame. He thought that great attention ought to be paid by engineers to the workpeople who were employed to do painting work. It seemed to be a prevalent idea that anybody was able to do painting work, and, in fact, till quite recently any paint was considered good enough. They might have the best material to suit certain purposes, but what the paintmaker could not do was to make paint foolproof. On examining so-called empty packages returned to them, the manufacturers often found half the contents at the bottom of the keg, and this was only one of many points which went to show the need for practical painters.

Mr. R. C. Bussell said that Mr. Depierres had mentioned in his paper that if he was given a specification it was the duty of any intelligent paint maker to endeavour to live up to it. In connection with that remark, and rising out of the remarks of the last speaker, the following seemed to him to be typical of the specification which would be drawn up by the average painter:—A paint that does not want stirring; to be applied by a casual labourer at night, in a fog, on a wet surface; a paint free under the brush which will dry hard at once with an elastic enamel surface, and remain so for ever.

Mr. Jennings said he would like to hear from the lecturer whether he considered natural graphite, which was practically pure, was more productive when made into paint than one which was mixed with, say, 50 per cent. of a material such as silica. With regard to imbedding iron in cement, during the last two years he had made some experiments with Portland cement as a protective paint for iron, and he thought that such a paint, if mixed with casein or a material of that nature, would make an excellent protective paint for iron. He thought Mr. Oliver's remarks as to results recorded by the Architectural Association showed conclusively that iron, when imbedded in Portland cement, did not rust. Regarding Mr. McIntosh's remarks as to opposite results being obtained in America, these results were probably due to the fact that in America very little Portland cement was used, and other cements did not seem so satisfactory for the purpose in question. He thought

ST. SWITHIN'S CHURCH, HITHER GREEN, LONDON, S.E. INTERIOR, LOOKING EAST. ERNEST NEWTON, F.R.I.B.A., ARCHITECT.

The nave and aisles of this church were built in 1892, and the chancel and transepts were added in 1903. The exterior is faced with Wrotham bricks and dressings of Box Ground Bath stone, all the exterior stone being whitewashed when finished. The roofs are covered with green slates. Internally the church has barrel ceilings, and the plaster is left rough-faced. The chancel floor is temporarily paved with red tiles; the altar hangings, stalls, etc., are also temporary.

---

there was a great future for a protective paint made from Portland cement.

Mr. Davis thanked Mr. Depierres for his very excellent paper, which had been very beneficial to him, and he thought it was particularly interesting just at this time, when so much steel was being used in building construction. He should like to suggest that this excellent and practical paper should be sent to a journal which was widely read by architects and engineers, as he felt sure it would be well received by members of the architectural profession.

In closing the discussion, Mr. Cruickshank Smith said that he should like to focus the attention of the Society in connection with this question of corrosion on two or three salient points. In the first place, it had been abundantly proved that linseed oil was a medium which, when in the form of a dried film, was permeable to moisture. That was a point which the paint maker and the paint user would do well to thoroughly realise. Secondly, Mr. Depierres only referred cursorily to a very important point, namely, the electrolytic theory in regard to the formation of rust. This theory was first of all brought forward by Wightman, and had now been elaborated by Dr. Cushman, of the Agricultural Department of the U.S. Government at Washington. Cushman had investigated the results both of Moody and his collaborators, and Dunstan and his collaborators, and had come to the conclusion that their results were only partially true, and he had elaborated a theory of his own based on electrolytic action. Cushman's investigation and experiments had brought about some very curious results in regard to pigments. When certain pigments were applied to iron, and exposed to influences which would under normal conditions induce corrosion, it was found that some of them retarded or even prevented corrosion. Cushman had therefore divided pigments into three classes, namely, inhibitors or preventors of corrosion, stimulators of corrosion, and indeterminates, the latter class including those which, according to the present observations, neither stimulated nor prevented corrosion. Thirdly, he thought they had heard from all the speakers sufficient to indicate that neither the paint maker working by himself, nor the paint user working by himself, was likely to arrive at a satisfactory solution of all the problems connected with the prevention of corrosion and the preparation of a satisfactory protective paint. It required the skill and technical knowledge of both the scientific manufacturer and the practical user to elucidate the problem, and he considered that it lay within the province of that Society to bring together the trained skill of both sides of the industry in order to see whether they could not advance the present fund of technical knowledge, and so help to bring about a solution of the difficulties that beset this question.

Mr. Depierres, in replying, said that with regard to Mr. Robertson's query in connection with oxide of iron, there were, of course, many grades and kinds of oxides of iron. Based on the electrolytic theory, magnetic oxide of iron has often been recommended as an inhibitor of rust, but, personally, he had been unable to find any advantage over the anhydrous ferric oxide. With regard to Mr. Robertson's query as to the existence of natural magnetic oxide, it is said that a ferric oxide is found in nature having magnetic properties, and of a light red colour, but it has never been offered on the market commercially. He could not agree that artificial oxide of iron was better than natural oxide.

Correspondence.

[The Editor declines responsibility for the statements made by correspondents.]

To the Editor of The Builders' Journal.

Sir,—In my previous communication on concrete bridges (three-hinged types) which you kindly inserted in your issue of May 26th, I mentioned that the Dusseldorf Exhibition bridge was eventually destroyed by means of strong explosives. May I now supplement the information given in the previous number with a brief account of the method of destruction as carried out by the contractors for the removal? The bridge was completely stripped down to the arch ring, wedge-shaped sections were cut out on each side at about 3 metres from the springing, approximately 1.25 metres in from each face, thus leaving about 6⅓ metres of arch ring, which was then drilled for 10 charges on a radial line, 60 centimetres in from the back or extrados, there being on the intrados the tension cracks from the test loading carried out previous by the German engineers. By the explosion of these 10 charges simultaneously at each hole, conical portions of concrete were blown out, and the neighbouring or surrounding portions were somewhat loosened without effecting the desired downfall. Then the workmen with hammer and chisel attacked the remaining sound portions, till only 1.7 metres remained, which was then blasted with three more charges, thus completely effecting the downfall of a somewhat remarkable structure. This bridge was a pure concrete bridge, no reinforcement being used at all in the arch ring. At the same time a side wall, partly supporting an 8-metre span reinforced concrete floor, was blown down, leaving the floor suspended in mid-air, thus acting as a somewhat wide cantilever, which was still used as a runway for loaded barrows, and workmen passing over same in complete safety till it was eventually demolished. Then, again, when 10 charges were exploded in an 8-metre wider floor, with beams carrying same (T-beam section), the result was not total destruction, but the expected conical hole formation with radiating cracks from the hole outwards, thus proving how tenacious the construction was. Herr Ducker and Co. were the contractors for the removal of the exhibition buildings devoted to concrete and cement.

These few particulars are given in the hope that they will counteract in some way or other the published reports of reinforced concrete failures, as given by papers with little or no knowledge of the subject. In conclusion, I would like to state that Herr Dyckerhoff gives the time increment of strength in a table published by him as follows: Amongst others a 1.6.10 mixture in kg/qcm. (kilogrammes per square centimetre) gave at 7 months 121 kg/qcm., at 1 year 165 kg/qcm., at 10 years 233 kg/qcm. Thus it will be seen the strength has increased nearly double that at 7 months. What would it be in 100 years assuming this rate of increase?

James Smyth.

THE LONDON COUNTY COUNCIL.

The London County Council, at its meeting yesterday (Tuesday), had under consideration the following recommendations (with others). In each case consent was advised by the Building Act Committee :—

Erection of buildings on the western side of Church Street, Chelsea, between King's Road and Elm Park Road, on the application of Mr. C. W. Stephens, on behalf of the Vale Estate Company, Limited.

Erection of buildings on the eastern side of Stamford Hill, Hackney, to abut also upon the southern side of Upper Clapton Road, on the application of Edmondsons, Ltd.

Erection of a building at No. 230, Lavender Hill, Battersea, with a one-storey shop in front, on the application of Mr. A. Whitelaw, on behalf of the London and North-Western Railway Company.

Erection of a building at the rear of the German Sailor's Home, West India Dock Road, and Rich Street, Limehouse, to abut upon Beccles Street, on the application of Mr. G. Waymouth.

Erection of a building on the site of No. 7, Fort Street, Stepney, on the application of Mr. F. Fox.

Rebuilding of the "Navy Arms" public-house on the eastern side of New King Street, Deptford, abutting also upon the southern side of Prince Street, on the application of Messrs. Wylson and Long, on behalf of Truman, Hanbury, Buxton and Co., Limited.

Formation of a new street for carriage traffic to lead from Tothill Street to Princes Street, Westminster, on the application of Drivers, Jonas and Co.

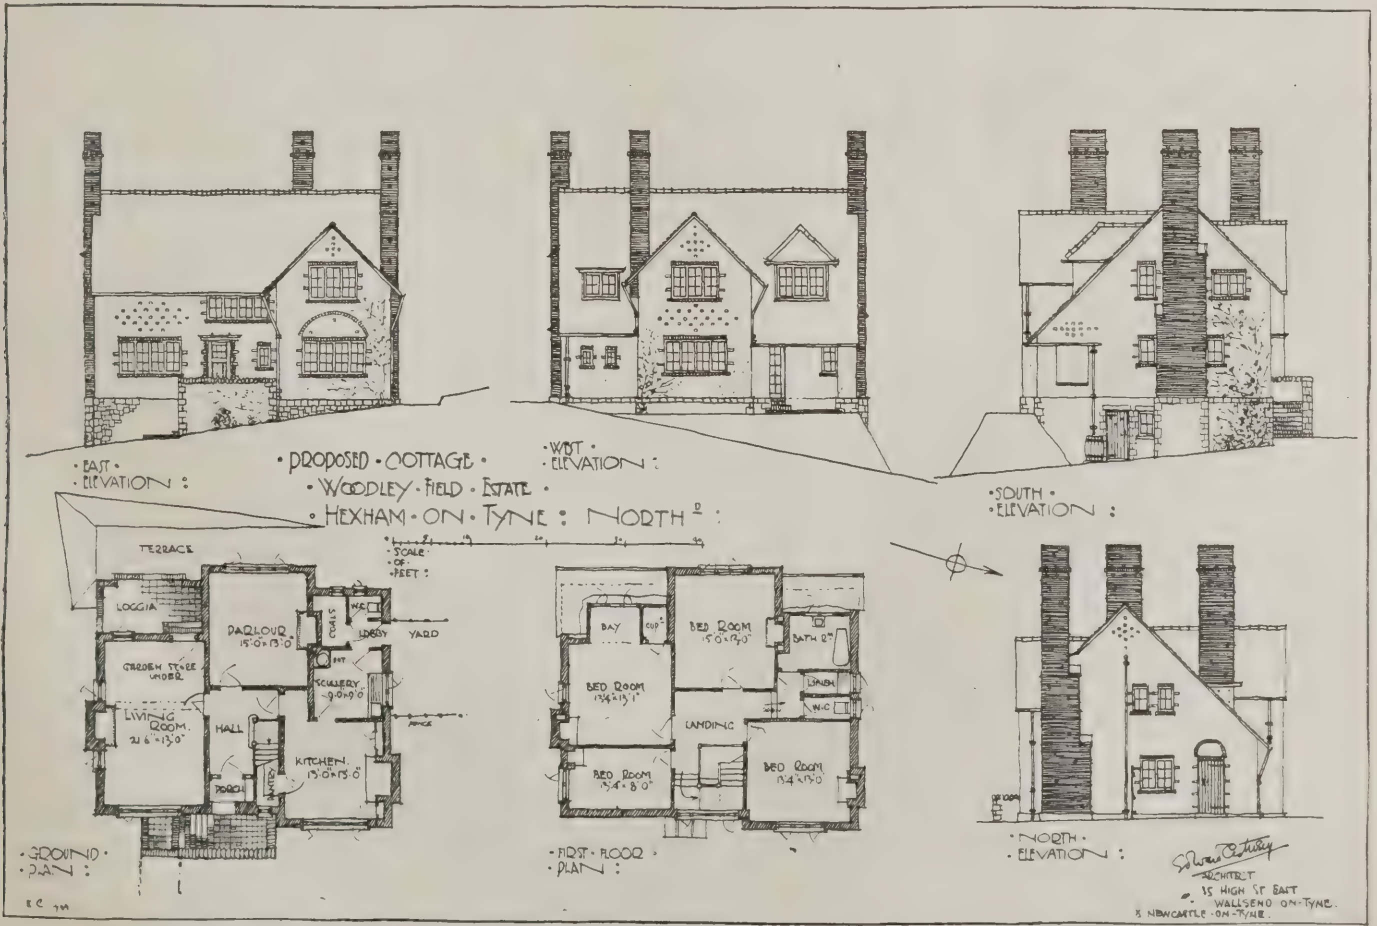
Erection of rooms upon the flat roofs of three buildings known as Sussex Mansions, Old Brompton Road, Kensington, on the application of Mr. W. H. Collbran.

Federation News.

LONDON MASTER BUILDERS' ASSOCIATION.

Secretary: T. Costigan.

The following fixtures for July were arranged:—Last Thursday, special Council meeting, 4 p.m.; Thursday, 15th, Council meeting, 4 p.m.; Organisation Committee meeting, 2.30 p.m. Meetings of the Institute of Builders, and of the Builders' Benevolent Institution, were announced under "Coming Events."



COTTAGE AT HEXHAM. EDWARD CRATNEY, ARCHITECT.

This cottage is now in course of erection, and is the first of a series of cottages to be erected on the Woodley Field Estate at Hexham. The walls are built of rubble up to the ground floor level and 11 inch brickwork above, rough casted with two coats Portland cement and dashed with white Derbyshire spar. The roof will be covered with red pantiles, and the windows will be wood casements opening outwards. The floor of the Loggia and the landing and steps at front entrance will be of brick on edge-set in squares. The contractor for this cottage is Mr. James I. Murray of Hexham, and the architect, Mr. Edward Cratney of Wallsend and Newcastle, who is also responsible for the laying out of the estate.

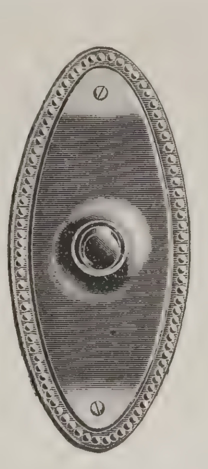

Fig. 2.

"NEW DEPARTURE" DOOR BELLS AND GONGS

Trade and Craft.

"New Departure" Bells or Gongs.

The ingeniously contrived clockwork bells or gongs introduced into this country from America several years ago have become very popular for various services, especially for the front doors of suburban houses. "All the latest modern conveniences," in small houses, are apt to include an exceedingly fragile electric installation, in which wires, bells, and batteries are, singly or in unison, so constantly out of order as to constitute a nuisance rather than a convenience. The "New Departure" door gong, as the writer happens to know from personal experience, completely relieves the householder of this threefold source of worry and vexation. It offers, as its vendors claim, "electric results without a battery." Very slight pressure on a button causes the gong to sound for as long as the button is held. There are gongs in which the necessary force to operate the striking mechanism must be applied direct. In the "New Departure" gong, however, the operating force is stored up in a clock-spring, and is released with a light touch on the button. The mechanism is wound up by simply turning the gong. Beyond doing this four or five times in the course of a year—and the winding takes but a few seconds—the apparatus requires no attention whatever. The writer has had one in use on a hard-worked front-door for about five years, and it has never given the slightest trouble. The fixing could hardly be more simple. There is nothing to do beyond boring a hole to take the push-wire between the clockwork on the inner side of the door and the button on the outer, and to screw the mechanism and the door-plate into their respective positions. The whole operation can be performed in about ten minutes. The sectional illustration (Fig. 1) shows the whole process at a glance. Fig. 2 illustrates one of the door-plates, of which there are many different patterns, plain and ornamental, in brass or bronze finish. There are also several types of apparatus, all, however, acting on the same principle, which is adapted to various requirements. A thumb-piece, turning both left and right, may be adopted instead of the push-button. By a simple arrangement of cranks, the gong can be actuated from a distance—as from front-door to kitchen, or from the inside of a carriage to the coachman's seat. The apparatus is also mounted on various kinds of stands, to form call-bells for tea-rooms, offices, etc., and there is a special arrangement producing an effective alarum for automobiles. A new and much cheaper model of door-bell is of the push-button (clockwork) pattern, and has a stamped dome and finger-plate instead of the cast dome and plate of the regular patterns. It will no doubt be largely used for the cheaper classes of dwellings. Messrs. John H. Graham and Co., 118-122, Holborn, London, E.C., are the agents in this country.

Messrs. Veritys' Electrical Supplies Catalogue.

Veritys, Ltd., electrical manufacturers, whose works are at Aston, Birmingham, and who have sale depôts in London, Birmingham, Bristol, Manchester, Liverpool, Newcastle, Glasgow, and Dublin, besides export offices at 31, King Street, Covent Garden, London, W.C., have found that, with the growth of the electrical industry, the wholesale catalogue in one huge volume has become too cumbersome for convenient service. Accordingly, the firm divided their catalogue into two volumes, one dealing with the heavier apparatus and supplies, the other with fittings. They have now carried subdivision a step further, dividing the catalogue into three volumes, which are of handy and portable size, and are strongly bound, while the paper, printing, and illustrations are wholly admirable. Such handsome books are pleasant to handle and to look upon; and the neat and durable case in which they are enclosed is a further concession to sightliness and convenience.

The first volume includes articles that Messrs. Verity do not manufacture, such as steam and gas engines and other prime movers, as well as pulleys and belting, etc., etc.

Boilers of all kinds—Cornish, Lancashire, and water-tubes, horizontal and vertical—are listed, as well as various types of engines and generators; suction gas plant and engines being of course included.

The second volume of the catalogue is labelled "sundries," and comprises sections on accessories; cables, conduits, and installation sundries; bells, bell material, and telephones and sundries; heating and cooking; and signs, illumination, and theatre apparatus. It enumerates all the minor requirements and details of electric installation.

The third volume shows a varied and comprehensive collection of fittings. The architect or decorator will here find ready to his hand designs that are applicable to nearly all the circumstances with which he is called upon to deal; but Messrs. Verity announce that they are always pleased to submit special designs and to arrange for draughtsmen's visits free of charge. In many respects this volume is more than a mere catalogue; it is by way of being a treasury of art—a fact for which one should be truly grateful, considering the extent to which electricity, having become an indispensable adjunct to the modern building, must now influence and modify, for good or ill, the decorative schemes of architects, builders, and decorators. At Aston, Birmingham, Messrs. Veritys have built up a great industry, employing, we believe, more than 800 persons; and it is indeed gratifying to observe, from evidence gathered on the spot, as well as from that which abounds in this excellent tripartite catalogue, that genuine art-craftsmanship is here so closely associated with sheer utility as to seem almost inseparable from it.

NOW PREPARING FOR PRESS.
NO. 12, 1909-10.
SPECIFICATION
With which is incorporated the
MUNICIPAL ENGINEERS' SPECIFICATION,
For Architects, Surveyors and Engineers when specifying.
SPECIAL ANNOUNCEMENT TO ADVERTISERS.
A limited number of pages will be reserved in each section for Advertisements, thus enabling Manufacturers to insert particulars of their Specialities in the advertisement columns actually facing the text dealing with the particular branch of the profession that interests them. Positions will be allotted according to priority of application.
ADVERTISEMENT RATES.
One Page - £10 per annum
Two Pages - £19 ,,
Four Pages - £36 ,,
Eight Pages - £65 ,,
Special positions by arrangement.
Measurements for space allowed for matter on Advertisement Pages:
Whole Page - 10in. deep by 7in. wide.
A Booklet, giving all particulars of this number, which is being thoroughly revised and brought up-to-date, will be sent upon application.
TECHNICAL JOURNALS, Ltd., Caxton House, Westminster, S.W.

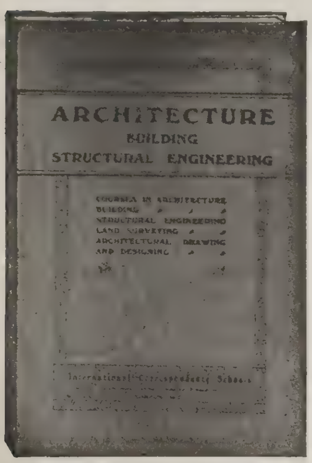
"NOTHING Comes to the Man Who Waits."

THAT'S the true version of the old proverb—as regards "promotion" at any rate. The man who is content to **wait** until promotion comes his way will take off his coat at 6 a.m. when he is 50, just as he did when he was 21—unless, indeed, he has been displaced before.

Will you be still "waiting" for promotion when you reach middle age?

You **need** not be, and it surely necessitates only a very little thought for you to determine that you **will** not be. By pursuing a course of practical, remunerative training **now**, you can ensure yourself a future of success and happiness instead of an unending repetition of "the same old grind."

You can get this emancipating training at home, in your spare time, and on terms to suit your pocket, through the International Correspondence Schools. During the past 17 years we have enabled thousands of men and women to secure a future free from anxiety. This is typical testimony from one of our students:—



Books on Subjects below free.

"I had a good opportunity of bettering myself, but my technical education was poor. Technical schools and evening classes I attended for four years, but found I was not getting the experience and knowledge I ought to have had. I got very disheartened. I made enquiries and asked for advice, and was told of the I.C.S. I joined the Schools, and never regret the day when I did so, as I have reaped the rewards which tend to advance me still further in the near future. Any fellow who is willing to learn and work has only to join the Schools and his success is sure. I thoroughly recommend the I.C.S. to any young fellow who wishes to become a success in life."

The reason of the sure success of the I.C.S. student is that the training we give him has **the one and only aim of qualifying him for an advancement** in his chosen line.

Isn't it well worth your while to learn what we can do to make **your** future bright? Mark the coupon, or write us about any other career in which you are interested. Don't "wait" another day.

Determine to "act" now.

80

Registrar, INTERNATIONAL CORRESPONDENCE SCHOOLS, Ltd., (Dept. B.), International Buildings, Kingsway, London, W.C.

I am interested in your system of Technical Training and desire to increase my earning power. Please send me, post paid, free of charge, the Book covering the subject before which I have marked **X** on the coupon, and full information showing how I can succeed in same.

The Renowned

Andrews-Hawksley

Patent Tread

Applied to Wood, Iron, Stone or Concrete Stairways, Floors, Landings, Platforms, Non-Conducting Floor Plates for Electric Light and Power Stations, Pavement Covers, etc., etc.

Pioneers of all Stair Treads.
The Tread that has lasted a lifetime.
There is nothing to equal it in the Market.

Architects and Engineers are invited to inspect our New Iron Staircase and Stair Tread made and laid by us at St. James's Park Station (District Railway).

Quotations given for Concrete Steps fitted complete with our Treads.

Quotations given for Concrete Steps fitted complete with our Treads.

Used by Great Western Railway, London and North Western Railway, London Brighton and South Coast Railway, Great Northern Railway, Midland Railway, North Eastern Railway, North British Railway, Lancashire and Yorkshire Railway, H.M. Office of Works, War Office, Admiralty, etc.

Specialists in Light Constructional Work in Iron or Steel; Special Work in Wrought or Cast Iron; Staircases of every description; Concrete and Granolithic Work, etc.

Fire Escape Staircases with our Treads, a Speciality.

A National Science Museum. The deputation of British men of science which, headed by Sir Henry Roscoe, waited upon Mr. Walter Runciman, President of the Board of Education, to present a memorial urging the desirability of providing a special building to accommodate the national science collections at South Kensington, presented a good case in convincing style, and received an encouraging reply. No other response was possible. Mr. Runciman was even constrained to say that he was ashamed of the present position, and he was perhaps prompted to that confession by the remark of Sir Hugh Bell, President of the Iron and Steel Institute, that one's national pride was hurt on going through a building at South Kensington which, erected fifty years ago as a refreshment room, is now found to be inconveniently crowded with what ought to be a very interesting collection showing the application of science to industry. The incompleteness of the collections is easily understood. People are reluctant to give or lend objects that, for want of a suitable building, cannot be properly seen, and are not, as they should be, as thoroughly protected from fire dangers as the latest developments of building construction would ensure. Consequently the collections do not increase as they ought; and it is but "Job's comfort" to reflect that there is really no room for expansion. Room must be made; and Mr. Runciman's gloomy observations as to the difficulty of obtaining a suitable site and the necessary funds, were anticipated in Sir Henry Roscoe's statement that land sufficient for the purpose is in the Government's hands; while the Royal Commissioners of the 1851 Exhibition offered, as long ago as 1876, to contribute £100,000 towards the proper housing of the collection. As Mr. Runciman promised to urge upon his colleagues of the Cabinet the importance of the subject, the prospect of seeing the new Museum of National Science in three dimensions before the century is much older does not appear to be hopelessly remote.

Cynicism or Despair. The amendment of the London Building Acts bringing them more up to date with regard to what is conveniently if somewhat inaccurately called "steel construction" is now virtually through the Parliamentary Committees. It has been decided that there shall be inspection of internal construction. This may tend to safety; but will certainly not tend to expedition, and the decision is greatly disappointing to architects, whose misgivings on this point are rather accentuated by the decidedly odd provision that appeal shall be referred to the police magistrate, who of all men is probably the one who is least qualified to deal with such matters. Obviously, he has neither the time nor the requisite technical knowledge for such matters; and, from every point of view, the police-court seems to be about the worst conceivable tribunal of appeal. There is one characteristic of the police magistrate, however, that affords a glimmering of hope. He is often amply furnished with strong common sense, native or acquired; and the chances are that he will at once perceive the impossibility of bearing the fresh burden that has been so inconsiderately imposed upon him, and will take prompt and strong measures to get rid of it. Reference to the police magistrate is perhaps not necessarily degrading, but it is certainly farcical, and one cannot help wondering whether this inept solution of an admittedly difficult problem was prompted by cynicism or by sheer desperation.

The Dullest Spot. How undecorative a people we are is signified in an appalling instance cited by "A Country Cousin," who writes to the daily Press to accuse the faithful Commons of maintaining the arid barrenness of "one of the dullest spots in the Three Kingdoms." Curiously enough, he (or she) applies this description not to the legislative chamber, but to the Terrace, which "stretches its gloomy expanse of pavement and its ugly parapet [shade of Barry!] devoid of all colour except such as occasional saucers of ripe strawberries foreshadowing guests may supply." It is suggested that a geranium or two, or the contents of a coster's flower-barrow would work a magical change without seriously affecting the supply of Dreadnoughts. This might possibly have commended itself to the lieges as a reasonable proposition; but unfortunately the correspondent lapses into poetry, lilting light-heartedly of "shrubs in painted tubs," and thus destroying, at once and for ever, all claim to attention from the dignified makers of our laws, whose minds are moulded to the severely Gothic lines of the building they adorn but do not decorate. Let the Terrace continue unbedizened, for in that blessed condition it fulfils a cardinal condition of good architecture—that the exterior of a building should express its character. What could be more appropriate than that the Terrace should remain "one of the dullest spots in the Three Kingdoms," seeing its entire relevancy to the dreariest spot on earth—the floor of the House?

St. Paul's Bridge. The proposal to build a new bridge over the Thames raises mingled hopes and misgivings. Will it be purely an engineer's production, or will it be a miserable compromise as between the engineer and the architect, the former constructing the skeleton, and the latter clothing it with more or less inappropriate ornamentation? Or will the Corporation take courage and have the bridge constructed of reinforced concrete. It should, in any case, be more than merely utilitarian—it should reflect somewhat of the dignity of London, and should both signalise and encourage that growing sense of beauty which is said to be in course of rapid development among its citizens. Here is a splendid opportunity of showing that we have lived down our old reputation of being merely a nation of shopkeepers, and that we have acquired some considerable regard for art and architecture—a polite assumption that would probably be negatived by those who are inclined to see in this very scheme a strong disproof or disclaimer of it. Among these may perhaps be counted a gentleman who has written to the daily Press to protest against the choice of a route which will bring the enormous traffic of a new "main artery" right under the walls of St. Paul's Cathedral. It has been frequently deplored, mainly by foreign observers, that grave injustice is done to St. Paul's Cathedral by allowing it to be closely hemmed in by warehouses, instead of surrounding it with wide-spreading greenswards; and it does seem a pity that there should be any danger of getting still farther away from that glorious but utterly unattainable ideal. The critic's more effective appeal is that which is the more likely to awaken panic fears: "A good deal was said about the new sewer through London endangering the foundations of the cathedral; but what would that damage be, compared with the damage arising from the construction of this subway, and from the constant running therein night and day of heavy tramcars?"—a feature of the scheme being, as we recently recorded, the construction of a subway for tramways running between the northern approach to the bridge at Cannon Street, and Aldersgate Street. A strong objection to the surface-level route is that it will cross, at very short intervals, two crowded main thoroughfares—Cannon Street and Cheapside—and, by adding to the confusion and congestion, will do more harm than good. The critic is in favour of abandoning the St. Paul's Bridge scheme, and of spending the money on a thorough improvement of Southwark Bridge and its approaches. He seizes hold of an expression to the effect that the expense of interfering with certain property in order to effect improved traffic accommodation would be "almost prohibitive." Some of the present congestion in this very neighbourhood, he points out, is due to the adoption of that argument on a former occasion when a great street improvement was planned. "When Queen Victoria Street was constructed, it was made a thoroughfare 65ft. in width, but the authorities were not prepared to do the thing thoroughly, and left an old street only 50ft. wide to form part of this new highway, so that the public has never had the full benefit of the expenditure on this improvement. At the Mansion House Station there is, in fact, a 'bottle-neck,' the effect of which is to make the extra 15ft. in width further down of no real value at all." This, surely, is a sufficiently striking illustration of the folly of false economy. A further objection to the new bridge is that if it is built there will then be no fewer than four bridges within a reach of 500 yards, spoiling the appearance of the waterway. Every scheme of any magnitude that was ever broached has been subjected to criticism, carping and otherwise, and most of it supremely negligible. It strikes us, however, that this particular critic has sound reasons for the faith that is in him, and that the authorities have hearkened unto his voice: for the scheme has been "referred back."

The Restorer's Retort. To affirm that the Society for the Protection of Ancient Buildings sometimes allows zeal to outrun discretion is only another way of admitting that it has the defects of its qualities. Its criticisms of the work of restoration now being carried on at Exeter Cathedral have apparently exasperated the local Press. "If," says a writer in the Exeter "Express and Echo," "the Dean and Chapter swept away the old work and substituted something of entirely different design, a strong protest would be in order; but seeing that the new portions are facsimiles of the old, criticism is captious. If the crumbling stones were not replaced, Exeter Cathedral would in course of time become a ruin. Is that what the critics desire? In that event, however, the title of the Society is a misnomer." The writer of this rather scathing rebuke thereupon proceeds to commit the most heinous and most characteristic fault of "the alleged restorer." Not content with destroying the old (title), he substitutes something that is not only new, but altogether obnoxious. The Society, he suggests, should be renamed "The Society for the Creation of Picturesque Ruins." This perhaps goes rather beyond the retort courteous; but perhaps it does not get so far as the countercheck quarrelsome. Let us call it the reproof valiant.

Street-lighting Systems. In order that London may not be the worst lighted city in Europe, the Corporation appointed a deputation to visit important Continental cities and report on the systems in vogue. They found that, as a rule, the main streets are lighted by electric arc lamps, and the side streets by incandescent gas—Brussels, Cologne, Berlin, Dresden, and Vienna all furnishing instances of this dual arrangement. The deputation report in favour of centrally-hung lamps, a system that has been for some time on its trial in Cannon Street and elsewhere. Open spaces, however—by which it is presumed are meant those places whose area is too expansive to admit of the application of the suspensory system—they propose should be lighted by means of lamps upon standards fitted with lowering gear, and that high-pressure inverted incandescent gas lamps should be adopted where practicable. The design of those standards, and of the fittings generally, should not be left to whim or chance. Useful by night, they should be comely if not ornamental by day; and as, when badly chosen, their effect on street architecture may possibly be absolutely revolting, the choice, if not the production, of patterns should be entrusted to competent architects, who will be at least able to ensure effects that are inoffensive. Another point upon which we have repeatedly insisted may be now opportunely urged again—namely, that any system of street lighting falls somewhat short of legitimate expectation if it fails to indicate street names. Finding one's way about London or its suburbs after nightfall ought not to be a matter of "trial and error." A proper system of street lighting and street labelling would relieve policemen and postmen of much extraneous work. But the illuminated labels need not, and must not, be hideous.

Buried Buildings. Diligent and persistent spadework in various parts of the kingdom is yielding rewards that justify the effort. At Caersws, Montgomeryshire, the old Roman camp, a curate, the Rev. D. Davies, attempted a serious exploration as long ago as 1854, when the foundations of a villa and baths were unearthed. The work was then abandoned, and the site was neglected until 1901, when some workmen excavating for the foundations of new houses made some discoveries of pottery, etc., which re-awakened the interest of archæologists. The camp, which is believed to be the largest of the twenty military camps constructed by the Romans in Wales during the second half of the first century, is now being systematically explored by the Liverpool Committee of Excavation and Research in Wales, in conjunction with the Powysland Club, who have found that the large rampart running round the camp was probably about 12ft. high, and that it was made of clay, with red sandstone dressing on the outside. Blocks of dressed sandstone, which must have formed part of an imposing structure, have been discovered, and a fine Roman road—oddly described, in a local report, as "macadamised"—21ft. wide. Excellent work is also being done by the Corbridge Excavation Committee, who have sent us a circular in which an appeal for funds is powerfully supported by an interesting account of what has been already accomplished. It appears that in 1906 the Northumberland County History Committee undertook trial excavations on the Roman site of Corstopitum, which lies a little to the west of the present Corbridge, and found sufficient to justify the supposition that the systematic and scientific uncovering of the site was well worth while. An Excavation Committee of scholarly composition was then formed, and began, in July, 1907, excavations that have been successful almost beyond expectation. The bridge over the Tyne has been traced, and for the first time correctly laid down in the map, the massive construction of its northern approach being laid bare, measured, and figured. A large building, with hypocausts, corridors, water supply, latrines, and (as it seems) an elaborate Bellevue overlooking the valley of the Tyne, has been uncovered. An ornamental water-tank yielded the Corbridge Lion, "the most remarkable piece of Romano-British sculpture yet found in the region of the Roman Wall, and indeed in the whole of Roman Britain." Other discoveries are—a broad street, flanked by substantial buildings; a fine inscribed slab (of about A.D. 140), illustrating the operations that led to the construction of the Wall of Pius from Forth to Clyde; a decorated drinking fountain of perhaps the same date; a pottery store that evidently had been burnt out; two large buttressed granaries, each nearly 100ft. long, faced within and without with "most admirable ashlar," and having mullions to the windows, one of which, remaining *in situ*, is perhaps the oldest mullion in the world; a bas-relief of the Sungod, in fourth-century style, is probably the best preserved sculpture of that age as yet identified in England; and another, of which an illustration is given in the circular, seems to show the myth (rarely depicted in Roman sculpture) of Bellerophon. It were quite superfluous to point out that such discoveries must have a considerable bearing on architectural history, whose roots and rudiments, it would seem, are underground.

Our Royal Academy Ballot.

Our proposal for a ballot with the object of ascertaining the names of those architects who, in the opinion of the profession, are worthy of the honour of election to the Royal Academy (for particulars, see last week's issue, p. 27) is meeting with the most gratifying success. The following list of names indicates the relative positions of twenty nominees, as indicated by the votes recorded up to the first post on Monday last:—

1. Lutyens, E. L., London.
2. George, Ernest, London.
3. Hare, H. T., London.
4. Newton, Ernest, London.
5. Pite, Professor Beresford, London.
6. Burnet, J. J., Glasgow.
7. Collcutt, T. E., London.
   Lorimer, R. S., Edinburgh. } Equal.
   Rickards, E. A., London.
   Stokes, Leonard, London.
11. Dawber, E. Guy, London.
12. Gibson, J. S., London.
   Lethaby, Professor W. R., London. } Eq
14. Caröe, W. D., London. } Equal.
   Flockhart, William, London.
16. Moore, Temple, London.
18. Mallows, C. E., London. } Equal.
17. Lanchester, H. V., London;
   Simpson, John W., London.
19. Brierley, Walter H., York.

It is hardly necessary to state that many other gentlemen have been nominated, and that further voting will no doubt modify the present list. The first round closes to-day.

BARNSLEY'S NEW COUNCIL SCHOOL.

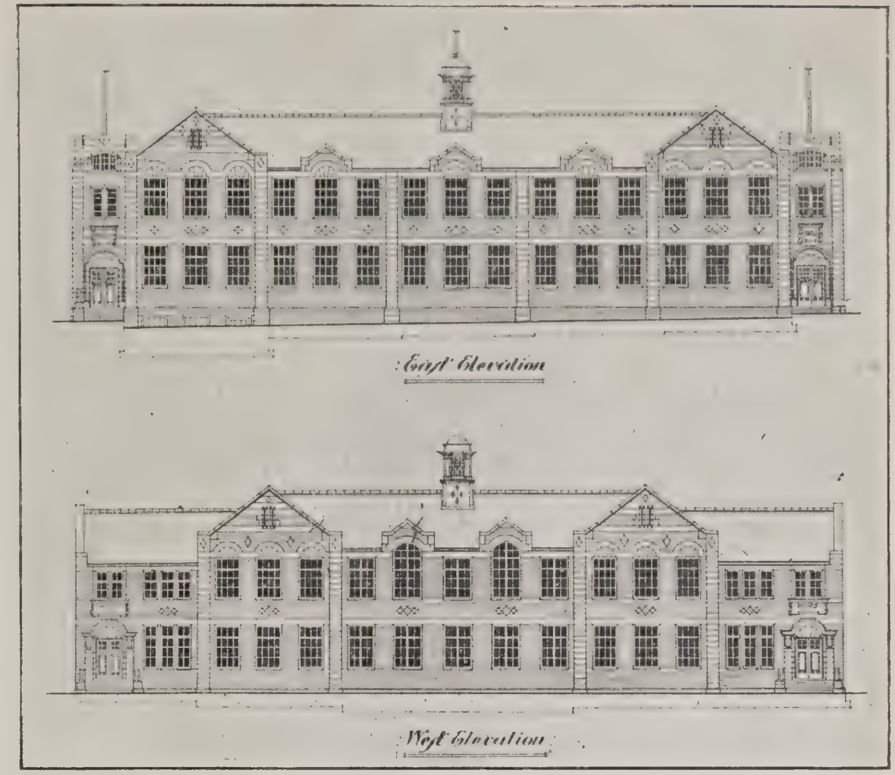
The Barnsley Education Committee invited architects to submit designs for the erection of a school in Grove Street for 900 children, in three departments, Mr. Herbert T. Buckland being selected by the committee to act as assessor.

The premiums offered were £30, £20, and £10, for the designs placed respectively first, second, and third, the premiums, in the case of the architect selected to carry out the work being merged in his commission.

It was stipulated that the drawings submitted should be executed in ink, in black and white (the elevations left unshaded, and no prospective allowed), and should consist of a block plan of the site, drawn to 1-20th in. scale, showing the position of the buildings, playgrounds, drainage, latrines, play-sheds, etc.; a plan of each floor of the three departments, indicating the desk and giving the position of the heating chambers; and longitudinal and transverse sections, and three elevations of the respective buildings—all to ⅛ in. scale.

The cost of the whole, exclusive of furnishing, was limited to £12 per head. Whilst the actual disposition of the buildings on the site was left to the discretion of the competitors, it was suggested in the conditions that it would be desirable "to so arrange the buildings as to leave the greatest possible area of the site free and square, and to give every room used for teaching an aspect which would ensure the admission of direct sunlight during some part of the school hours."

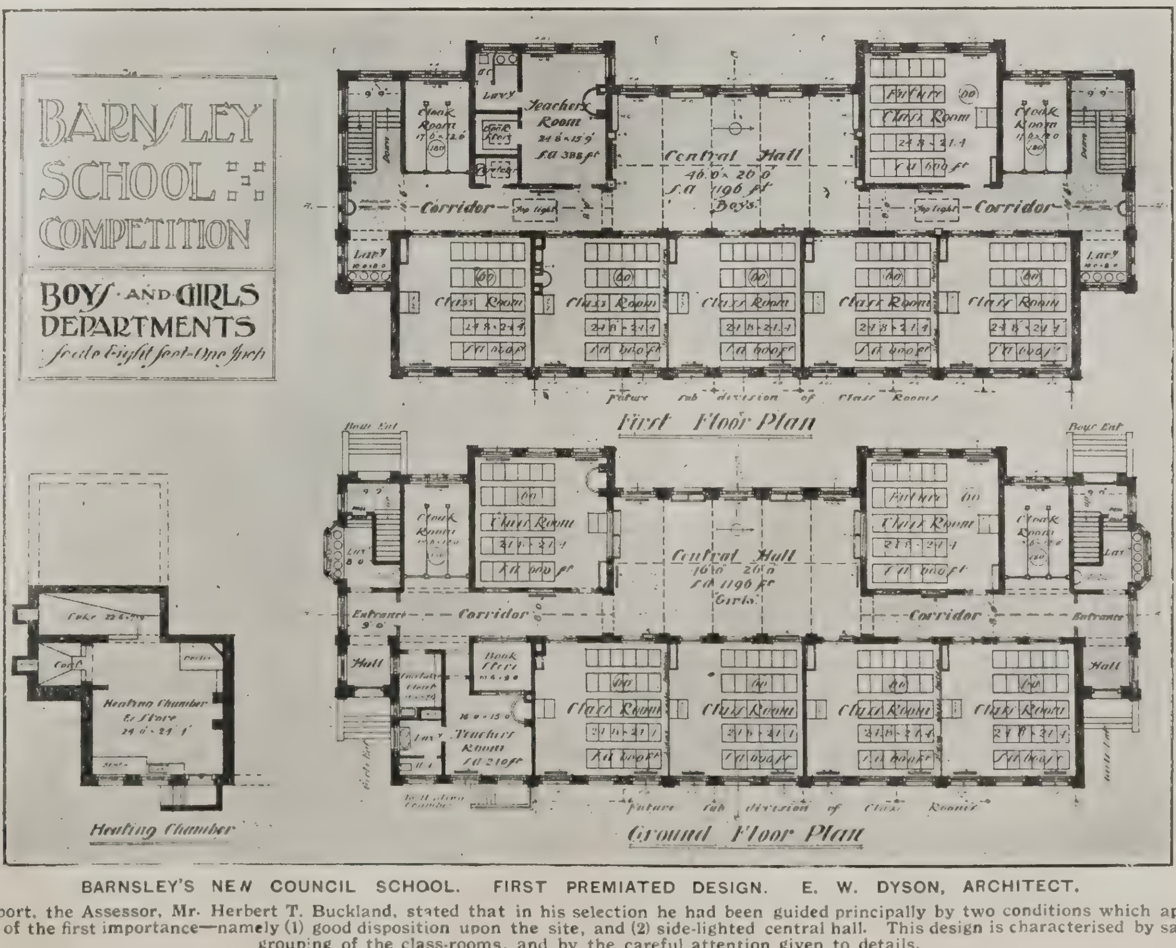
The conditions require the schools to be built in two blocks, to provide accommodation in three separate departments, for 300 boys, 300 girls, and 300 infants; the plans submitted to allow for the possibility of an additional classroom (60 being added to the accommodation of each department—the competing architects being left to determine for themselves which of the two departments it would be most satisfactory to include in the same block.



BARNSLEY'S NEW COUNCIL SCHOOL. FIRST PREMIATED DESIGN.
E. W. DYSON, ARCHITECT.

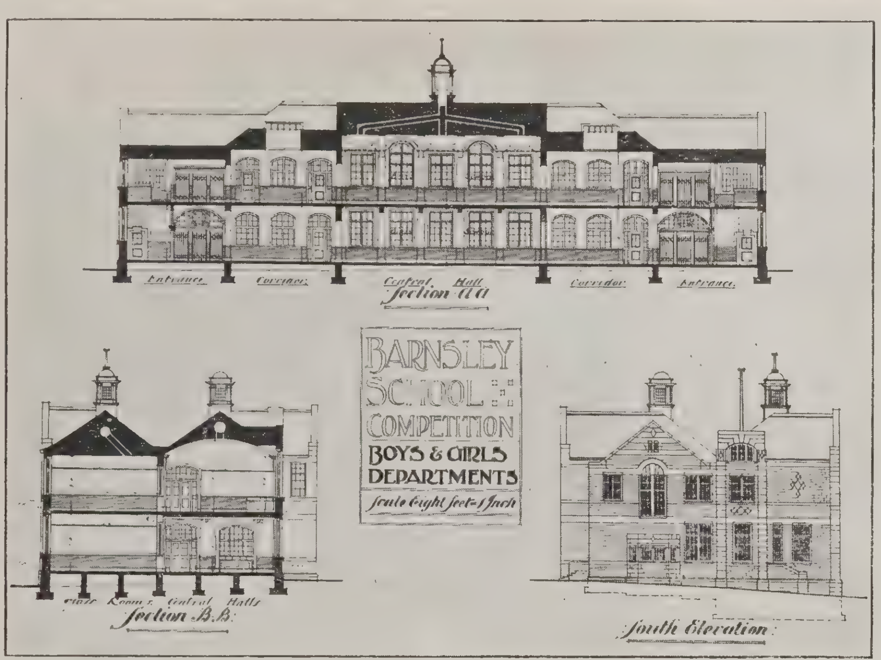
In the elevation of the boys' and girls' block, perfect symmetry is evident, an advantage that has not been obtained at the expense of competent planning.

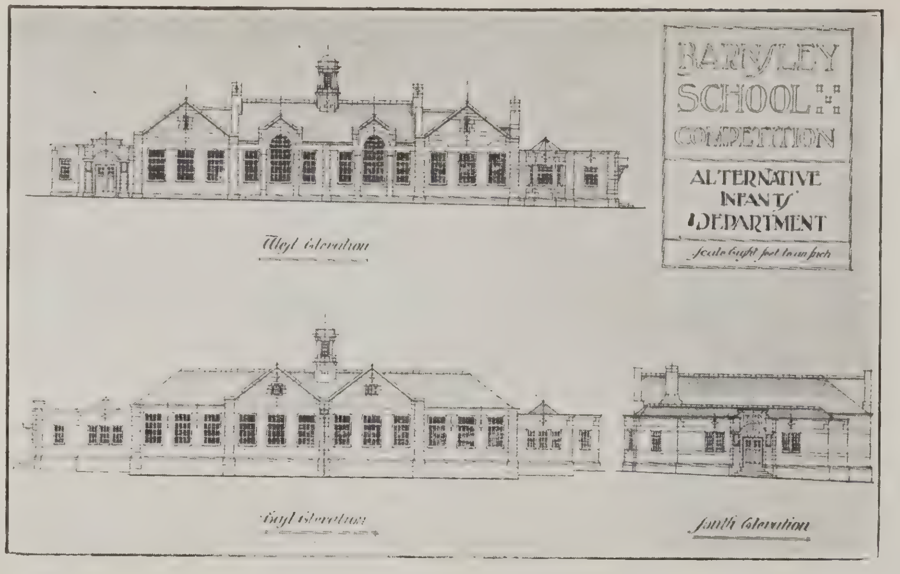
It was required that each department should be arranged with an assembly hall and five class-rooms, each class-room to be capable of accommodating 60 pupils, and four of the class-rooms in each department to be arranged in two pairs of two each, a folding partition of wood and glass separating the class-rooms forming a pair. The rooms were to be so disposed that the folding partition could at a later date, if necessary, be placed in another position, and a second partition added, so as to break up the pair of class-rooms into three rooms, each capable of accommodating 40 pupils.



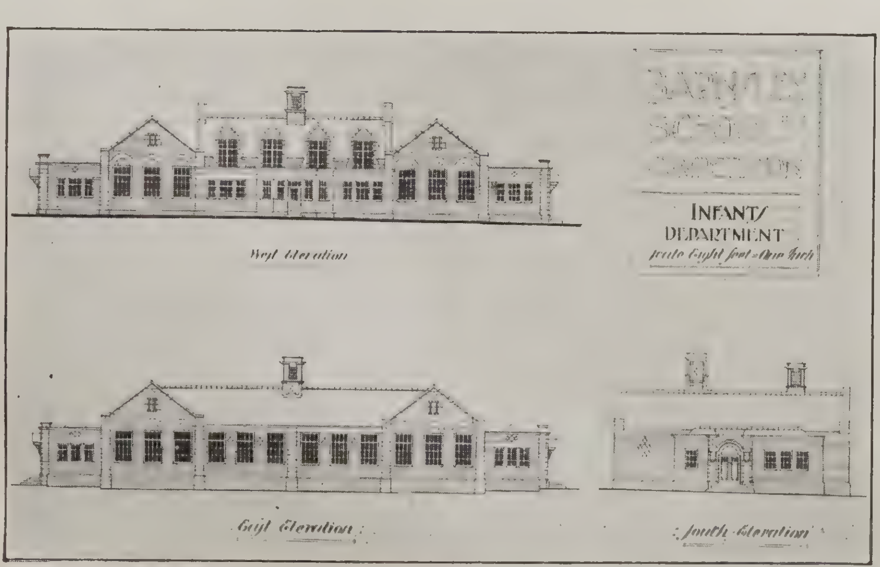
BARNSLEY'S NEW COUNCIL SCHOOL. FIRST PREMIATED DESIGN. E. W. DYSON, ARCHITECT.

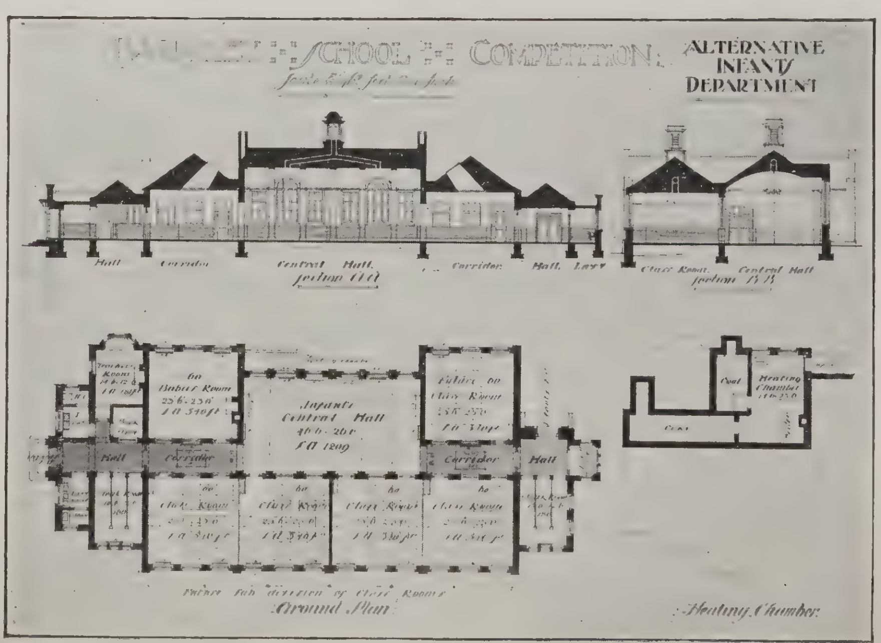
In his report, the Assessor, Mr. Herbert T. Buckland, stated that in his selection he had been guided principally by two conditions which appeared to him to be of the first importance—namely (1) good disposition upon the site, and (2) side-lighted central hall. This design is characterised by satisfactory grouping of the class-rooms, and by the careful attention given to details.





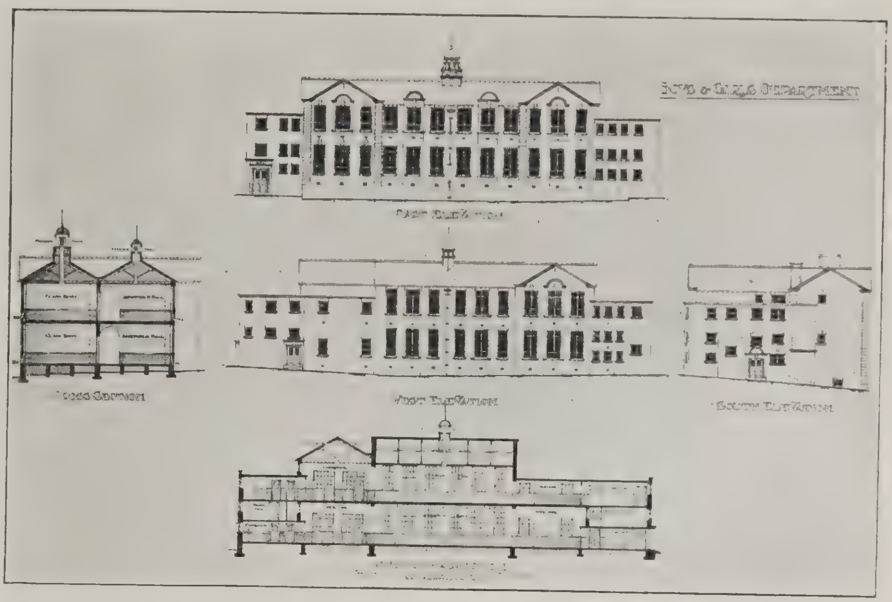
BARNSLEY SCHOOL COMPETITION
ALTERNATIVE INFANTS DEPARTMENT
Scale Eight feet to one Inch
West Elevation
East Elevation
South Elevation





BARNSLEY'S NEW COUNCIL SCHOOL. FIRST PREMIATED DESIGN. E. W. DYSON, ARCHITECT.

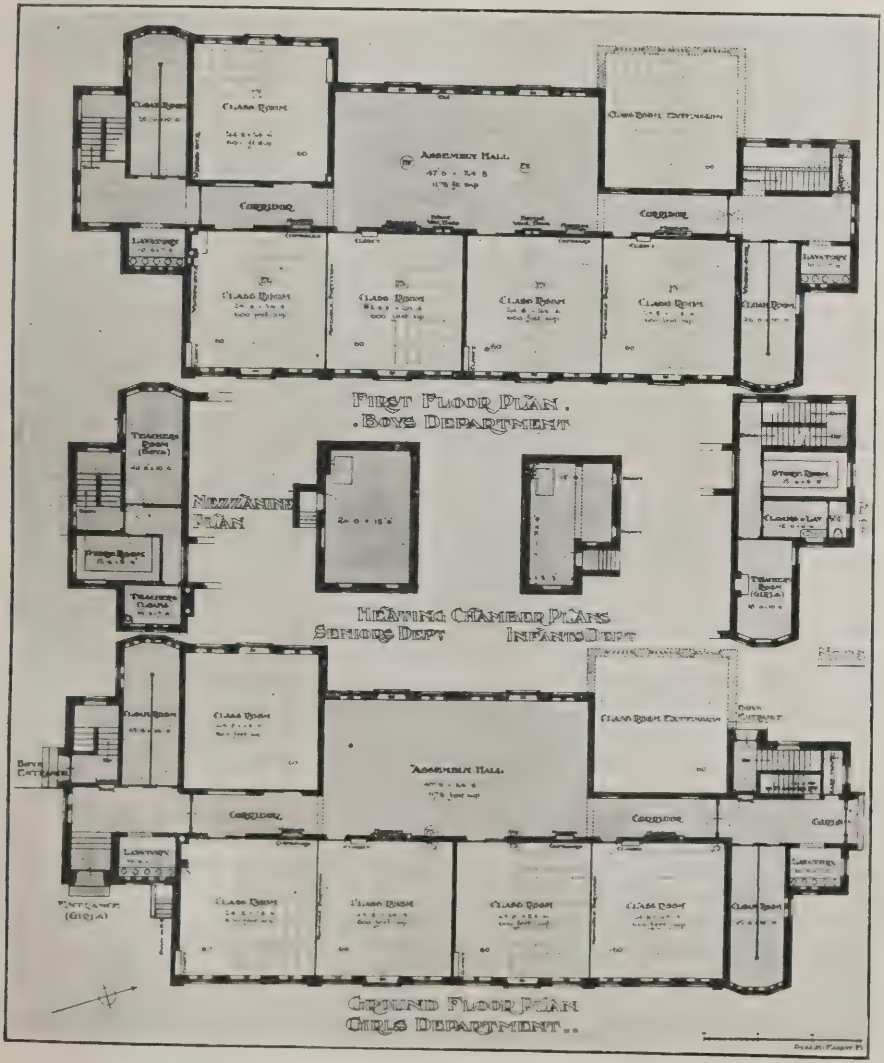
Sections are here shown of the boys' and girls' departments, and elevations and alternative elevations of the infants' department. The original scheme for this latter department shows the teachers' room and lavatories at one side of the main hall, with windows above. This gives better supervision, perhaps, than the alternative design, but prevents the entire side of the hall from getting direct light for a certain proportion of its height.



The additional accommodation required for each school was to include:—A teachers' room, not less than 150ft. in area, and placed so as to have full oversight of the respective playgrounds; a store-room; a heating chamber cellar in the basement, with ample storage room, and coal and coke chutes; lavatories and cloak-rooms, the former to be so arranged as to be accessible when the cloak-rooms are locked, the latter to be provided with separate openings for ingress and egress. In every room it was required that the main light should, as far as possible, be derived from the left-hand of the scholars, and in all classrooms in each of the departments an open fireplace was to be supplied. The offices were to be placed well away from the school buildings, separate w.c. accommodation being provided inside the buildings for female teachers. The respective playgrounds were to be laid with concrete or granolithic paving, and to have a playshed open on one side only. The school buildings were to be faced "with stone of approved quality," and the roof to be covered with green Westmorland slates. The utmost attention was to be devoted to the adequate ventilation of the various rooms.

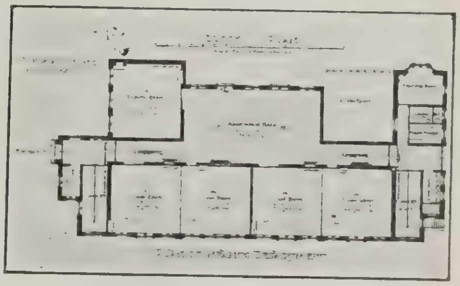
The selected design is the work of Mr. E. W. Dyson, 10, Regent Street, Barnsley; Messrs. Holtom and Fox, Corporation Street, Dewsbury; and Messrs. Clarke and Moscrop, Feethams, Darlington, being responsible for the schemes placed second and third respectively.

In his report, Mr. Buckland stated that in his selection he had been guided principally by "two conditions which appeared to him to be of the first importance:" (1) Good disposition upon the site, (2) side-lighted central hall. With regard to the first, as the site has a rapid decline of about 1 in 6, from west to east, its lower portion is best suited for the infants' school; as to the second, since the school must be in two blocks, side-lighted and well-ventilated halls are rendered possible, and no good reason can be advanced for surrounding them by class-rooms to the detriment of adequate lighting and ventilation. The next important point, in Mr. Buckland's opinion, was the consideration of the grouping of the departments. From motives of economy, it seems expedient to place the boys' and girls' departments one over the other, as each requires the same floor area. If, as in the case of some of the plans, the girls are placed over the infants, the rooms for the latter have to be made larger than is actually necessary in order to afford accommodation for the girls' area.



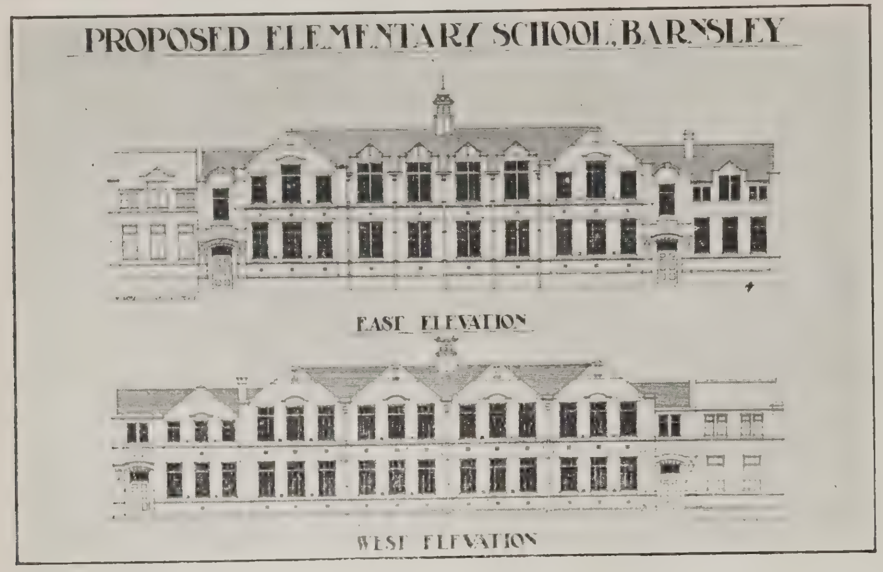
BARNSLEY'S NEW COUNCIL SCHOOL. SECOND PREMIATED DESIGN.
HOLTOM & FOX, ARCHITECTS.

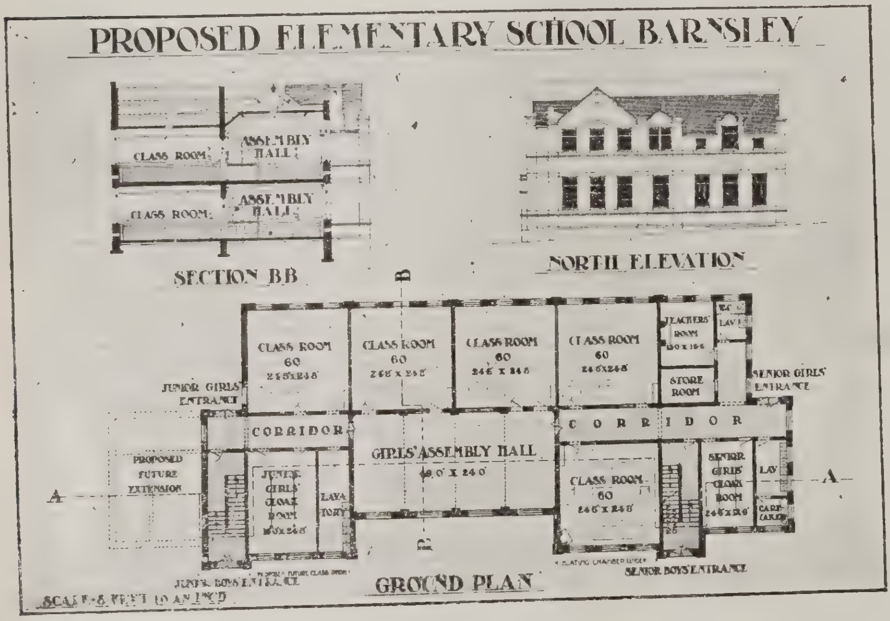
In this design the architects have evolved a commendably convenient grouping of class-rooms in relation to the central hall in the boys' and girls' block. It is perhaps to be regretted that more accurately balanced elevations were not obtained; but the general solution of the problem evinces real knowledge of the practical requirements of school planning.

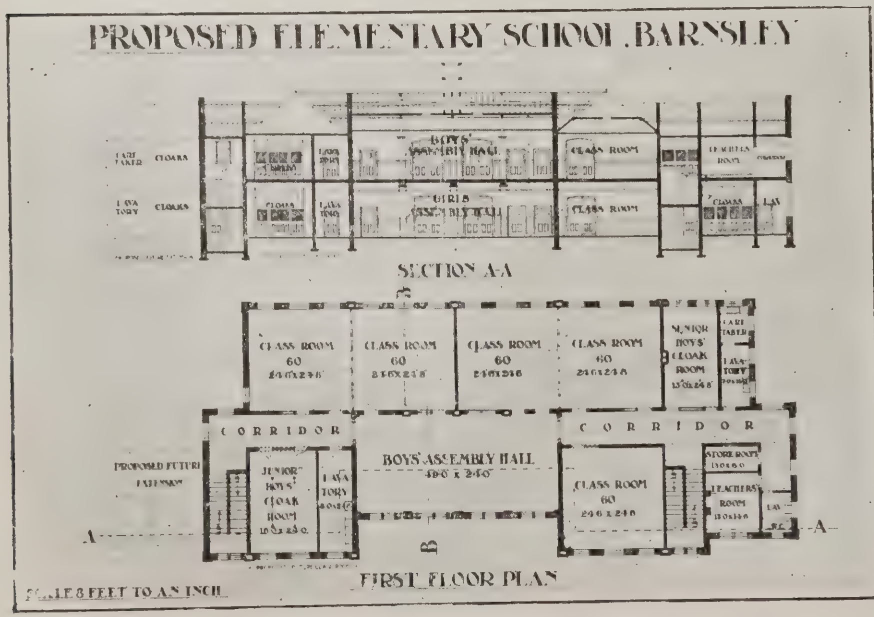


With regard to Mr. Dyson's arrangement, Mr. Buckland suggested that in order to guard against a through draught it might be advisable to alter the south entrance so as to face west, and that in the case of the playsheds for girls and infants, a sunny aspect would be preferable to their present northern one.

We entirely agree with Mr. Buckland in commending the thoroughly satisfactory grouping of the class-rooms and the careful consideration given to details in this design. It will be seen that the disposal of the blocks in each of the premiated schemes is practically identical—the parallel arrangement being obviously called for by the nature and shape of the site—and also that each of the successful competitors have so disposed their departments that the girls and boys are grouped together in one block of two storeys in which the girls have the ground floor and the boys the first floor, there being distinct entrances to each on opposite sides of the building. In the selected design the provision of lavatory accommodation and the placing of the cloak-room appears to us to have been admirably managed. The author has seen fit to submit an alternative infants' department. The original scheme shows the teachers' room and lavatories at one side of the main hall, with windows above. This gives good supervision—in fact, better than that obtained in the second arrangement—for the class-rooms (though perhaps not for the cloak-rooms), but prevents the entire side







BARNSLEY'S NEW COUNCIL SCHOOL. THIRD PREMIATED DESIGN. CLARKE & MOSCROP, ARCHITECTS.

The planning in this design contains many excellent features; but, on the whole, we should be inclined to endorse the judgment of the Assessor in placing it third.

of the hall from getting direct light for a certain proportion of its height. For the teachers themselves doubtless the alternative scheme is more satisfactory, but the arrangement results in a somewhat ill-balanced front. Still, in the elevation of the boys' and girls' block perfect symmetry has been obtained—an advantage over other designs which examination shows has not been gained at the expense of competent planning.

Messrs. Holtom and Fox, in the second premiated scheme, appear to us to have evoked a commendably convenient grouping of class-rooms in relation to the central hall in the boys' and girls' block. But the placing of the teachers' room on the mezzanine floor, although it might be very desirable for the teachers, is not quite all that could be desired from the point of view of organisation. It is to be regretted, we think, that more accurately balanced elevations could not be obtained, and their actual composition seems to us capable of improvement. The general solution of the problem, however, evinces a real knowledge of the practical requirements of school planning.

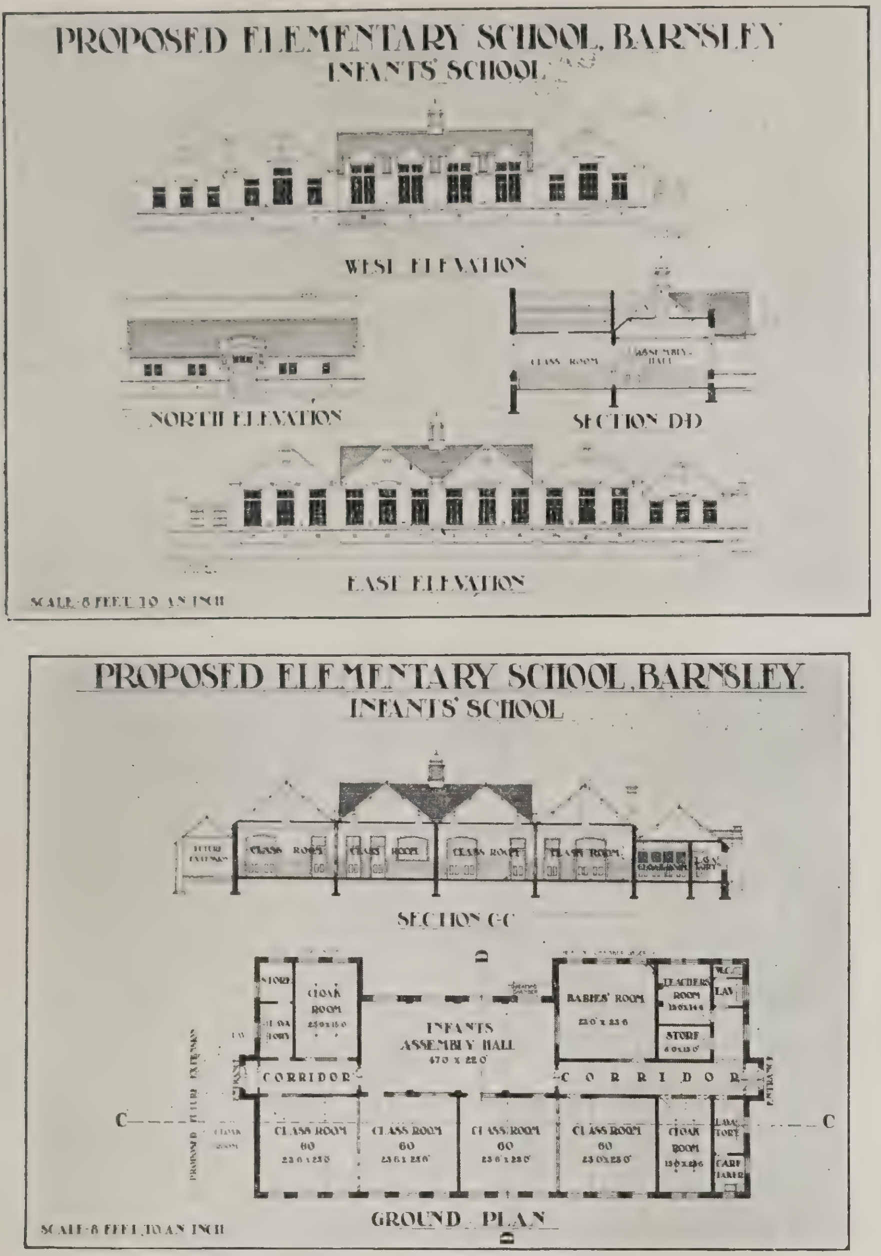
The third premiated design, that of Messrs. Clarke and Moscrop, departs from the general arrangement adopted in the first and second, in that the infants' block is placed away from the road, and all the departments—boys', girls', and infants'—have each separate playgrounds. In the other two schemes it will be seen that the girls and infants have to share a common playground. This latter arrangement does not appear to us to be so satisfactory. In the writer's opinion, the planning, though containing many excellent features, does not, on the whole, quite reach the level of the first and second designs.

Societies and Institutions.

University of Sheffield: Department of Architecture.

A prospectus issued by the University of Sheffield states that the Department of Architecture in that University was founded at the desire of the Sheffield Society of Architects and Surveyors, which society is associated with the Council and the Senate of the University in the management of the department. The Lecturer is Mr. W. S. Purchon, and Sir Aston Webb, C.B., R.A., chairman of the Board of Architectural Education, and Mr. Halsey Ricardo act as visitors.

The department provides (1) a systematic course of training for students wishing to become architects, to be taken by them before entering an architect's office, though not necessarily before they are articled; (2) an advanced and continuous course of study for students during their pupilage, and also when they become qualified assistants. Either course is open to those who are already in architects' offices, and students who are unable to take a complete course may, by arrangement, attend any part or parts of a course, subject to the approval of the Lecturer. The University will grant first-class and second-class certificates to students who complete their courses and pass the examinations at the end of the two years' day certificate course, and there is an advanced course for diploma. The courses are adapted to the requirements of the examinations of the Royal Institute of British Architects, and students obtaining first-class certificates countersigned by the visitors at the end of the two years' day certificate course will, subject to certain conditions, be exempted from the R.I.B.A. Intermediate exam. The Lecturer is assisted in the work and supervision of the advanced course by leading members of the architectural profession in the city, and by members of the staffs of various departments of the University. Messrs. C. F. Innocent, J. B. Mitchell-Withers, and J. R. Wigfull lecture on English Architecture, and Mr. E. M. Gibbs, F.R.I.B.A., has classes in Design.



BARNSLEY'S NEW COUNCIL SCHOOL. THIRD PREMIATED DESIGN. CLARKE AND MOSCROP, ARCHITECTS.

In the third premiated design, the infants' block is placed away from the road, and each of the departments has a separate playground.

CONTINENTAL STREET LIGHTING.

The Corporation of London recently appointed a deputation to visit several Continental cities for the purpose of inspecting the various systems adapted for the lighting of public thoroughfares; and the deputation has just reported the results of its investigations to the Court of Common Council.

The members state that in the main thoroughfares, squares, and market places of Brussels the illumination is by means of electric arc lamps with an ordinary incandescent gas-burner on each side. The arc lamps are turned off at midnight, after which time the lighting is supplied by gas. The side streets are lighted by incandescent gas. In Cologne the important streets of the city are lighted by centrally-hung electric arc and flame lamps with lowering gear; the open spaces by a combination of electricity and gas, and the minor streets mainly by incandescent gas lamps upon standards. In Dusseldorf a somewhat similar system is in vogue, while in Berlin the general arrangement for lighting is by means of electric arc lamps centrally hung and upon standards, electric glow lamps, and high pressure incandescent gas lamps with inverted mantles. In Dresden the electric arc lamps are of the open and flame type, a considerable number being suspended across the streets with side lowering gear. The side streets are lighted with low-pressure incandescent gas lamps, while the electric lamps are switched off at midnight, leaving incandescent gas lighting only. In Vienna the mode of street lighting is by means of arc lamps upon standards with incandescent gas lamps fixed on brackets below, together with low-pressure incandescent gas lamps fitted with upright and inverted mantles. Particulars are also supplied concerning the street lighting in Paris and Munich.

The members of the deputation state that, having very carefully considered the various systems, they are of opinion that the public lighting of the City of London can be materially improved, and recommend that wherever possible streets should be lighted by means of centrally-hung lamps with lowering gear, having in view the number of obstructions existing upon the footways in the shape of lamp-posts, bins, and letter-boxes. They propose further that the open spaces should be lighted by means of lamps upon standards fitted with lowering gear; also that high-pressure incandescent gas lamps with inverted burners should be adopted as the illuminant, but that where gas is impracticable electricity with open arc and flame arc lamps should be installed. It is proposed that before any drastic alterations in the general lighting of the City take place some further experimental lighting should be made.

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
July 30	GRIMSBY TOWN HALL EXTENSION. Estimated cost £26,000. Conditions of competition sent to any applicant on receipt of a stamped addressed foolscap envelope. Full particulars, schedule of requirements, plans of existing buildings, etc., on receipt of deposit £2 (cheques to be made payable to Frank Stephenson, Borough Treasurer), which deposit will be returned to those who send in designs, or if the whole of the particulars are sent back within ten days from the date of their receipt by the applicant. Premiums of £250, £150 and £100. An Architect of eminence will advise in conjunction with the Borough Engineer. Applications to be made to the latter, H. G. Whyatt, Assoc.M.Inst.C.E., Town Hall, Grimsby.
July 31	LAYING OUT ESTATE AT EASTWOOD, RENFREWSHIRE. The patrons of the Royal Incorporation of Hutcheson's Hospital, Glasgow, invite competitive designs for laying out for feuing and building their lands of Thorniiebank, containing about 195 acres. Particulars, conditions, and skeleton plans from the Chamberlains to the Hospital, Hill and Hoggan, 194, Ingram Street, Glasgow, to whom designs are to be sent. Premiums, £100, £75, £50, and £25 for the first four designs, *which will become the property of the patrons, who will not be bound further to employ the authors.* Deposit, £3 3s.
Aug, 30	FOREST HALL, Elementary school for 250 scholars. County of Northumberland Education Committee invite designs from architects practising in the County and in the City and County of Newcastle-on-Tyne. Particulars, conditions and plan of site from C. Williams, Secretary to the Education Committee, The Moothall, Newcastle-on-Tyne.
Aug. 31	HUDDERSFIELD NEW CHURCH. Plans are invited for a church to seat 400, to cost about £2,000, not to exceed £2,500, with all fittings, furnishings, lighting and heating apparatus. Plans to be forwarded to the Rev. D. Macræ Tod, B.D., St. James' Manse, Huddersfield, by Aug. 31.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.
Sept. 20	HULL TRAINING COLLEGE for teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.

Mr. Jules Clement Chaplain, the French sculptor, who was a native of Mortague, Orne, has died in Paris. A pupil of Jouffroy, he won the Prix de Rome in 1863. He had real talent for plastic expression, and his technique was equal to his inspiration. Equally successful in imaginative work and portraiture, M. Chaplin produced noble pieces of statuary such as "L'Inspiration," a portrait of "Gambetta," and a charming group, "Mes Enfants." He was a member of the Institute of France, an Officer of the Legion of Honour.

Correspondence.

[*The Editor declines responsibility for the statements made by correspondents.*]

Middlesbrough Library Competition.

SIR,—We have now received the following reply to our letter of the 30th ult., from the Royal Institute of British Architects, in regard to the above competition:—

"9th July 1909.

"*Middlesbrough Library Competition.*

"DEAR SIRS,

"I am desired by the Council of the Royal Institute to inform you that your letter of the 30th June, addressed to the President of the Royal Institute, has been laid before them by the President, and as a result of their enquiry into the subject of your letter, I am to inform you that the decision of the Competitions Committee has the approval of the Council.

"Faithfully yours,

"(Signed) IAN MACALLISTER, Sec.

"MM. Hoskins and Brown, Kitching and Lee, and W. H. Bourne, Houndgate Chambers, Darlington."

We now propose taking counsel's opinion as to the position of the competitors in this competition.

Would those architects who signed the memorial, who have not yet forwarded the 5s. asked for, for preliminary expenses, kindly do so at once?

We should also be pleased to receive subscriptions from any other architects who sympathise with the object in view.

Any future action, after counsel's opinion is obtained, will be left to the subscribers.

Whatever counsel's opinion may be, architects will at least have the opportunity of knowing their legal position in future competitions.—Yours faithfully,

HOSKINS AND BROWN,
KITCHING AND LEE,
W. H. BOURNE, A.R.I.B.A.

Houndgate Chambers, Darlington.

Proposed New Works.

CAMBRIDGE.—A L.G. Board enquiry has been held into an application by the Town Council for consent to appropriate certain land belonging to the Council as sites for working-class houses.

GLASGOW.—The following linings have been granted:—John McNair, builder, 59, Bath Street, to erect tenements of dwelling-houses in Keppochhill Road, Alford Street, Gourlay Street, and Carlisle Street; Dick and Benzie, Forth Street, Pollokshields, to erect a villa in Eglinton Drive, Kelvinside; Rev. Wm. Booth, General of the Salvation Army, to erect halls on the north side of Flemington Street, Springburn; Wm. McMillan, builder, 73, Smith Street, Govanhill, to erect tenements of dwelling-houses in Garnet Street, Mount Florida; Richd. Henderson, architect, 80, Mount Annan Drive, to erect a villa in Kinmount Avenue, Highbury Park; J. and T. Parker, builders, 86, Bluevale Street, to erect buildings to be used as a post office sorting hall in Hillfoot Street, Dennistoun; George Outram and Co., Ltd., 65, Buchanan Street, to take down the existing buildings and erect new buildings at 7-9, Mitchell Lane.

GLENAFTON.—The Northern District Committee of the Ayrshire County Council have resolved to extend the accommodation of the Ayrshire Sanatorium by 20 beds at a cost of £4,609 14s. 2d.

GUILDFORD.—The Guardians are considering a scheme for the enlargement of the workhouse.

HAPTON (ACCRINGTON).—A great extension scheme is about to be carried out at Messrs. Riley and Sons' chemical works. The enlargement includes the erection of structures which will cover nearly four acres of ground.

HORNSEY.—The following plans have been approved by the Borough Council:—Plans for dwelling-house in Creighton Avenue, Muswell Hill, submitted by Mr. Charles Tucker; plans for motor shed at No. 37, Muswell Rise, Muswell Hill; plans for six dwelling-houses in Fortis Green Avenue, by Mr. George Henry Paine, Moorgate Street; and plans for five dwelling-houses and two maisonnettes in Priory Road, Hornsey, submitted by Mr. Charles William Boswell, The Parade, High Street.

HOUGHTON.—The Plans Committee recommended that the plan of a new temporary theatre be approved, so far as the Council could or legally may in the case of a temporary building, subject to an agreement being signed by the owners to remove the structure on six months' notice.

LONDON.—Mr. H. V. Lanchester, F.R.I.B.A., has prepared a report as to the suitability and adaptability of sites in the Borough of Marylebone, suitable for a new town hall. The two sites recommended by Mr. Lanchester are—one in Seymour Place, with an area of 27,150 sq. ft., which can be rented on an eighty years' lease for £750 per annum; and the other in Marylebone Road, with an area of 20,622 sq. ft., which can be purchased for £30,000.

LONDON.—The County Council have approved the erection of a garage on Wormwood Scrubbs, which is to house the French airship to be brought over for trial in August or September. Mr. H. O. Ellis is the architect.

ROSCOMMON.—The Town Commissioners having agreed to put the Housing of the Working Classes Act in force, it has been decided to apply for a loan of £7,000 for the erection of 25 cottages. Where possible, the houses will be built in terraces. They will be two storey, with terra cotta fronts, and each is expected to cost between £175 and £180, independent of the cost of site. Mr. Heavy, Four Roads, has been appointed to prepare plans and specifications.

ROTHWELL.—The vicar is appealing for a balance of £800 out of the £2,000 required to complete the restoration of the Parish Church.

SALTHOUSE.—The school buildings are to be enlarged in accordance with the requirements of the Board of Education.

SOUTHPORT.—Plans for a new music-hall have been submitted to the Corporation for aproval. The building, which it is proposed to erect in Lord Street, between Eastbank Street and Portland Street, is to have seating capacity of a little over 2,000 people. Mr. G. E. Tonge, of Southport, and Mr. Bertie Crewe, of London, are the joint architects.

SOUTHPORT.—The Southport Swimming Club has approved a scheme by Mr. T. Morris, architect, for the construction of two bathing pools, one for each sex, each 100ft. long by 40ft. wide in the North Marine Lake. The proposal is to be urged upon the municipal authorities.

WILLESDEN.—The Middlesex County Council and the Willesden District Council have decided to contribute £2,000 in connection with the enlargement of the Kilburn Training College.

Works in Progress and Completed.

BARGOED.—An English Wesleyan Chapel school is being erected here at a cost of £1,290. The school is part of a scheme which will include a chapel. Mr. William Harris, Bargoed, is the architect and Mr. John Brown, Bargoed, the contractor.

BELFAST.—The new church of St. Columbkille, Upper Newtownards Road, has been completed from the designs of Messrs. E. and J. Byrne.

BEVERLEY.—A new Baptist church is being erected here at a cost of £4,000.

BOWHILL.—The new public hall, erected by the Bowhill Public House Society, Ltd., has been opened. The hall is about 90ft. long and 50ft. wide. It will seat close upon a thousand people, and there are on each side of the main entrance door two "crush" halls. On either side, running the whole length of the public portion of the hall, is a corridor, 6ft. 6ins. wide, from which the large hall can be entered by a number of through swing doors. The stage is 42ft. long by 27ft. broad, and it is to be equipped to suit either variety or drama. Below the stage, off a spacious underground corridor, there are two large committee rooms. Messrs. Swanson and Syme, Kirkcaldy, were the architects, and the contractors were:—Mason, J. Summerville, Cowdenbeath; joiner, D. Arnott, Cardenden; iron and steel work, A. Brown and Co., Edinburgh; plumber, S. Binning, Cowdenbeath; slater, C. Stewart, Cardenden; plasterers, W. and J. Easton, Kirkcaldy; glaziers, A. Cunningham and Co., Edinburgh; heating, M'Kenzie and Moncur, Ltd., Edinburgh; and furnishings, Bennett Furnishing Company, Glasgow.

BRADFORD.—The new nurses' home at the Fever Hospital has been completed. Other alterations and additions to the hospital have brought the total cost up to £9,000.

CHESTERFIELD. — Messrs. Williams Deacon's new bank, at the corner of Stephenson Place, has been opened. The builders were Messrs. J. Collis and Sons, of Chesterfield. Mr. Thomas Taylor, of Eckington, was responsible for the joinery work, while the heating apparatus was installed by Mr. W. Haslam, of Harstoft, and electric lighting by Messrs. Alvey and Bower, of Chesterfield. Mr. F. Hill was entrusted with the plaster decoration, while Mr. R. Blake contracted for the painting. The architect was Mr. W. Cecil Jackson, M.S.A., of Chesterfield. The whole of the exterior of the building is faced with Stancliffe stone, the interior walls are lined with faience, the floors are of marble and oak blocks, and the whole of the internal fittings are of mahogany.

DOVERCOURT.—A new county high school is in course of erection on an elevated site near Blue House Farm, on the main Dovercourt to Colchester road. The building is to accommodate 136 scholars, and is to have facings of red brick, with dark red tile roof. The floors and staircases are to be of fireproof construction. All the classrooms have a south aspect, and the Assembly Hall, which is 24ft. 6ins. wide, and nearly 60ft. long, is designed to accommodate a possible extension of the school. In the west wing on the first floor, a commodious room, fitted for cookery instruction and scullery work, will be provided. Adjoining the cookery-room will be a dining-room for the use of children coming from a distance. The first floor of the east wing will consist of a chemical laboratory, with a chemical store and balance-room attached. There are also rooms for the headmaster and his assistants, and the boys are further provided with a workshop, detached from the main building. The architects are Messrs. Brown and Burgess, of Ipswich, and the contractors Messrs. Spencer, Santo, and Co., of Felixstowe.

LONDON (DALSTON, N.E.).—The Dalston Theatre is being altered and enlarged. Mr. George Billings, London Wall, E.C., is the architect, and Messrs. Stapleton and Sons, Stoke Newington, are the contractors.

MANCHESTER.—New offices for the Bowker Trustees are now being built in Strutt Street, Manchester, on the site of the "City News" old premises, from designs by, and under the supervision of, Mr. John Brooke, architect, Manchester. The whole of the constructional steelwork, fireproof floors, and granitic finishes are being carried out by Messrs. Homan and Rodgers, Manchester.

ONICH.—A new church, to seat 260, is being erected from the designs of Messrs. L. and J. Falconer, of Fort William. Messrs. E. and D. Stewart, Kinlocheil, are the contractors.

WIMBLEDON.—The new Pelham School, designed by Mr. H. P. Burke Downing, F.R.I.B.A., has been opened.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

Short Formulæ. For the design of reinforced concrete many methods of calculation have been put forward. They, however, generally conform to one type, which is that favoured by the Joint Committee on Reinforced Concrete, by the French and German Governments, and by American by-laws. It would appear in these circumstances that the matter was definitely settled and placed beyond the caprice of designers, and that practical knowledge and deep study of the subject was of very little moment. In the design of reinforced concrete the principles upon which these calculations are to be based appear to be so well founded that it seems almost as though any student having the ability to understand these rules would be able to design structures in reinforced concrete perfectly satisfactorily. We find, however, that, as a matter of fact, there are very few engineers competent to design in reinforced concrete, and that these few are men of considerable practical experience, or who have at all events devoted much study to the subject. Mere rules do not to any great extent help the inexperienced designer. Even if he avoids serious errors he is apt to err on the side of excessive cost. That theory without practice is not all-sufficient for the reinforced concrete designer, is proved by the competition of engineers employed by firms engaged in the commercial exploitation of this method of construction. Engineers differ very considerably in their methods of preparing schemes, but as a general rule the successful and prominent engineers are those who do not employ the elaborate methods for calculation that have been put forward. No doubt these methods are logical, but as a rule there is insufficient time to employ them; and, furthermore, when they are employed, they result in the work being as a rule more expensive than that designed on the ordinary shorter formulæ. There are many advantages apparently, in the employment of an elaborate theory, especially in respect to the fact that by its use so many minor points are covered which in certain circumstances become important in their effect upon the resistance of the structure. If the short formulæ are used by inexperienced persons, grave errors may be made; but the long formulæ have great disadvantages which almost preclude their use in practical designing. In the first place they are very cumbersome to use, taking a great deal of time because they entail so many factors; and this loss of time implies a great deal of labour that is spent on the preparation of schemes only a small proportion of which mature. Secondly, their very elaboration leads to the possibilities of great mistakes. The use of shorter formulæ enables designs to be got out much sooner, but they are not so very accurate, after all; they, just as much as the elaborate formulæ, require to be used with intelligence. But an experienced designer knows their deficiencies, and seems easily able to see from inspection in certain circumstances that other factors have to be taken into consideration. In short, all formulæ need to be applied with common sense; and when we can obtain just about as satisfactory results in a shorter time by employing rough formulæ, the latter seems to be the better course. The more elaborate formulæ are perhaps indispensable for checking work that is in doubt. We may here remark that to some extent the disadvantages in the way of loss of time in the employment of elaborate theory can be off-set by the use of graphs or tables—preferably the former, because these graphs enable one to ascertain the mistakes much easier than from an inspection of a table. In fact, the curves on these graphs automatically check each other. Such diagrams can be comparatively easily compiled, and their use is extending. But even then it is more probable that greater advantage can be obtained from the judicious use of the shorter formulæ. These formulæ are shorter because they reduce or eliminate certain factors, and the ordinary elaborate formulæ can be reduced down to fairly convenient form.

Where Elaborate Formulæ Fail. We also take this attitude—that it is needless to employ an elaborate theory where variations in the materials and workmanship affect the result so greatly. It is no use calculating out to several places of decimals when the reinforcements can never be placed with great mathematical exactitude, and the materials vary so considerably, and their manufacture also varies within reasonable limits. Not only that, but these elaborate formulæ have been drawn up upon certain assumptions which are in accordance with the results of tests; indeed, we have found from the results of numerous tests that the theory, with modifications to suit, does not even then account for the ultimate resistance developed in many cases. We can easily understand results being less than as calculated, because of variation in the materials and places, but we cannot admit the theory to be correct when we find the results of tests exceed the strength that can be calculated by making the most generous assumptions. If then, the ordinary theory errs so considerably, why should we forbid the use of simple rules? The theorists are getting too much sway. Practice and common sense are very essential to the efficient designer, and it is for this reason that the design of reinforced concrete is in the hands of so few engineers. We rather doubt the efficacy of the proposals that the general practitioner—engineer and architect—should take up the design of reinforced concrete.

Unproved Assumptions. The subject is far more difficult than appears at first sight, and we see no advantage in wasting material and labour. There is nothing really to show that the designs prepared by specialist engineers are deficient in stability. The only mishaps that have occurred have been due to bad workmanship, the designs have practically never been shown at fault. It is therefore rather questionable whether it is advisable to limit reinforced concrete firms as to the theory which they should employ. There is no doubt about the rules drawn up by the R.I.B.A. Joint Committee on reinforced concrete erring on the safe side. That is all very well in its way, but it would be better if specialist firms were allowed to take advantage of their superior skill and knowledge. There is no "jerry-building" in reinforced concrete, and it seems, therefore, to us that it would be undesirable to increase the cost of building construction in this country by the imposition of rules that are based upon assumptions that have not been adequately proved as yet. Some firms possess the results of elaborate experiments, and point to a large amount of work that has been designed in accordance with the rules determined from consideration of these experiments. To show that these rules are sufficient in practice to secure an efficient and stable structure, and in the present state of our knowledge it would be better to rely on such empirical rules than upon official rules, our argument comes simply to this, that if the R.I.B.A. theoretical rules are to be admitted as safe, then we ought still more to admit those empirical rules which have every evidence of successful employment to support them.

Reinforced Concrete in the Colonies. Great interest seems to be displayed among Colonial architects and engineers on the subject of reinforced concrete, and also in the uses of ordinary plain concrete. It seems strange that architects and engineers in practice abroad, removed from centres of culture, and working often in small townships or situated in the midst of a native population, should apparently take more interest and be much keener on new subjects in connection with architecture and engineering than do a large number of practitioners in this country, but such seems to be the fact. Probably these men abroad feel much more the need of education, and the desirability of keeping in touch with the latest advances, than do architects and engineers in this country, who seem to think that any important new developments are sure to be forced on their notice. The man abroad, too, is more willing to experiment and investigate the merits of any new system. We find that the proportion of professional men abroad who closely study modern developments in construction is far greater than the proportion interesting themselves in such matters who are resident in this country. Perhaps it is because the profession in England is becoming rather stagnant. The country is overcrowded, and great works of construction are naturally fewer here than in the large undeveloped areas of a comparatively new country. We have built most of our large works, whereas these other countries are rapidly developing. As regards reinforced concrete, however, one of the reasons which has led to the considerable interest which is displayed among professional men resident abroad is that in these new countries there is not the same facility for obtaining the ordinary materials. Stone is there in plenty, perhaps, but there is a want of masons to work it. Bricks are perhaps to be obtained, but in small quantity and not in sufficient variety. Timber has its disadvantages, and cannot be used for permanent work. It is subject to the ravages of ants, and liable to decay by other means. Generally, too, all skilled labour is scarce, and the expense of the ordinary older methods is excessive. Concrete has the advantage of being easily manufactured by unskilled labour under a smaller amount of supervision from anyone skilled in the work. Plain concrete needs only manufactured material consisting of cement, and this can be easily manufactured in many places with a small plant; and though in others it is at present only obtainable by importation, it is thus to be obtained at a comparatively cheap price; and as it forms only a small bulk of the concrete this does not hamper its use. The same applies to reinforced concrete, though in many cases we find high prices are realised for steel, but the proportion necessary to meet requirements of structural members is so small that it likewise does not affect the matter materially. On the whole, reinforced concrete is comparatively very much more economical in the Colonies than it is in this country, though the prices of cement and steel are much larger than here. Compared with other materials, therefore, concrete, and reinforced concrete, are very cheap, and their efficiency very great. We find that they possess great advantages in many directions in this country, so in possessing still more advantages abroad it is no wonder that they are coming into extensive use. Therefore, we can begin to understand how it is that the Colonial architect and Colonial engineer take great interest in the subject. We have seen illustrations of a good deal of work that has been put up abroad successfully in concrete for which we should not have contemplated its employment. We may, for instance, refer to the large number of concrete houses that are being erected in New Zealand. The building trade in that country is extremely active, and the country has made great progress, and is settling down and requiring the erection of numerous domestic buildings. Large houses of elaborate architectural character, even artistic in appearance, are being erected by architects in concrete, while engineering structures of all kinds are carried out in reinforced concrete. The price of steel is very much higher in such countries. For instance, in New Zealand apparently it costs about £14 per ton for ordinary commercial sections. In that country there do not appear to be any prospects of local steel works being established, and steel is not obtainable from Australia. No doubt, a few years hence, steel of Australian manufacture will be obtainable, but it appears that by that time the competition that is experienced in this country between steelwork and reinforced concrete work will not be in evidence, because reinforced concrete will hold the field. The steel will be used in small sections, in which form it will be more readily obtainable than in joists or angles or T's, and of which stocks may be more readily kept, and so be more speedily obtainable. The future for concrete and reinforced concrete in the Colonies is bright, and its advance there has been made possible by the enterprise of local professional men in their study of the subject. Many of the Colonial architects and engineers are going into the subject sufficiently deeply to be able to design the work themselves, an attitude which is noted by its absence from among those at home, though perhaps the architects now being trained in our schools will be more cultivated in this respect. An example is set by our Colonial brethren which we should be glad to see followed by those in this country.

Strength of Columns. A point in the calculation of the resistance of reinforced concrete columns that requires careful consideration and investigation is eccentric loading. It is very difficult to determine what are the proper rules to find the eccentricity of any load upon a column. In steelwork we have been accustomed to take the load as coming half-way upon the bracket attached to the column; but with reinforced concrete, with the large brackets that are employed—chiefly because of the reverse bending moment at the supports—it has to be decided whether this is the correct procedure, because the eccentricity calculated in this way is so considerable. In fact, it would appear almost preferable to employ a smaller bracket, or no bracket at all if one could provide a sufficient moment of resistance over the support without its use. The problem becomes still more in doubt in connection with external columns round a building. Here beams rest upon the columns, generally upon brackets, but even then there appears to be no means of determining the value of the eccentric loading. Some rule is badly wanted in this respect, and the only suggestions in the matter that have been put forward up to the present are, that the size of the columns should be increased slightly, or else a richer concrete used. The former is done by limiting the stress upon concrete to, say, 400lb., instead of 500lb. per sq. in. This, however, is decidedly unsatisfactory, because in acting in this way we do not know that we are on the safe side. With a very wide-span girder it seems possible that we may get considerable eccentricity; and, again, if the column is extra long, this eccentricity becomes more serious.

Also, the fixing of the ends of the beams might be considered with advantage. Where external columns extend one above the other for several floors, for instance, and the beams come into the middle of these columns, the load on the column certainly fixes the end of the beam to a considerable extent. Indeed, it might be made to fix it completely, in which case the bending moment in the centre would be $\frac{W}{24}$. It ought to be possible to determine what is the real action in such cases. We think it is a point which might be closely considered by specialist engineers with a view to enlightening the profession upon the subject. The problem is not exactly a small one. It often arises, and it is really time we had some guidance in this direction apart from practice in the employment of a higher factor of safety, which seems at the present time to be the customary method of overcoming the difficulty.

RECONSTRUCTION IN FERRO-CONCRETE.

Reconstruction has recently taken place of the Tynemouth Palace, which is a massive building erected on the high ground of one of the most picturesque portions of the Northumberland coast. The building was originally erected, at a cost of about £120,000, as an aquarium and winter gardens. The premises and land cover an area of about three acres, and in the Palace itself the principal department was a large concert hall, with sitting accommodation for more than 2,000 persons and a promenade space for an additional 500. On the lower floor below the concert hall there is another large hall, equal in floor space to the concert hall, and 20ft. high, formerly used as an aquarium. This has now been transformed into a roller skating rink, and for this purpose the floor had to be specially prepared, and obstructing pillars removed. In order to effect these changes, the stage then existing at the north end of the hall had to be removed and a modern erection substituted, along with up-to-date flies and scene grill, as well as a handsome ornamental fibrous plaster proscenium. The whole of the concert hall ceiling has been treated in the same manner.

For the former quite level floor, a sound and fireproof of sloping floor has been substituted, affording from every seat a clear view of the stage. The front portion of the hall is used for stalls, and the rear for second stalls and pit, with standing room or promenade at the back of the hall. The old galleries which ran along each side of the hall have been superseded by a curved tier circle, and the side walls of the hall from the stage to the circle front have been panelled in fibrous plaster, giving the hall increased dignity and securing better acoustic results.

In the skating rink, which is about 210ft. long by 50ft. wide, the floor has been specially treated and laid with white maple. The old aquarium tanks on the west side have been done away with, and their roofs glazed in order that the rink shall be naturally lighted during the day-time. The tanks on the east side, after the old fronts were removed and the arches made good, have been converted into a spectators' gallery, 3ft. above the floor of the rink. The skate stores are placed at the south or main entrance end of the rink, and cloak room accommodation is provided on each side of these stores.

In the architectural treatment, a Georgian style has been carried out on broad lines.

The whole of the building construction, in ferro-concrete, was carried out by Mr. W. T. Weir, builder, of Howdon-on-Tyne. The details of the ferro-concrete work were designed on the Hennibique principle. The two rows of iron pillars on which the concert hall rested have been done away with, leaving a clear span of 50ft. in the skating rink. The cantilever principle, for which reinforced concrete affords excellent facilities, has been adopted for the gallery, pillars to support the tiers being thus dispensed with.

The official tests of the grand circle gallery and concert hall floor were conducted under the supervision of Mr. J. F. Smillie, Borough Engineer of Tynemouth. The instruments used for registering the deflections were sensitive to a deflection of 1-500th of an inch.

The gallery promenade has a span of 49ft. 9ins., and the total area of the floor put under test was 49ft. 9ins. by 23ft., or an area of 1,144 sq. ft. The normal superload for which the floor is calculated is 200lb. per square inch, making a total load of 102 tons on the beam tested. In order to ascertain the deflections on the beam tested, three

In the reconstructed concert hall a noteworthy feature is the treatment of the ceiling in ornamental fibrous plaster.

TYNEMOUTH PALACE. GENERAL VIEW OF SKATING RINK.
MARSHALL & TWEEDY, ARCHITECTS FOR THE RECONSTRUCTION.

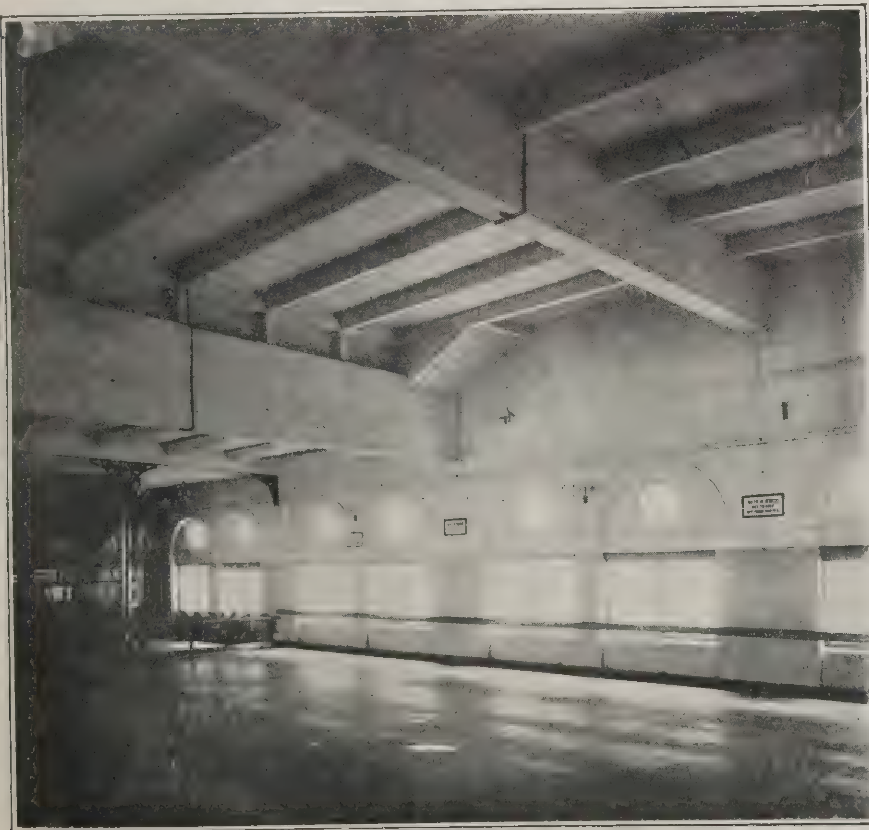
The building was originally erected at a cost of about £120,000, as an aquarium and winter garden. The large hall formerly used as an aquarium, has now been converted into a skating rink.

instruments were used. Under the full load the maximum deflection was 1-20th of an inch. In the gallery, which was tested on the same day, the span of the main beam is 49ft. 9ins., the total area tested being 49ft. 9ins. by 19ft., or an area of 945 sq. ft. The normal superload for which the gallery is calculated is, as before, 200lbs. per sq. ft., making a total load of 85 tons on the beam tested. For this test five instruments were used. On the main beam the readings of the deflectometers were as follows:—Deflector 1, within 1ft. from the support, nil. Deflector 2, at the middle of the beam, 3.5 m/m. Deflector 3, within 1ft. of the opposite support, nil. The deflection was therefor hardly 1-7th of an inch. As the deflection allowed by contract was 1-600th of the clear span of the beam, the test clearly demonstrated the strength of this construction, having regard to the fact that the gallery had only been completed 30 days before.

A further deflector was placed on the edge of the balcony, which registered 3.5 m/m, and a fifth placed midway between the main beam and the second beam at the back, which registered 1.3 m/m. With regard to the fourth deflectometer fixed on the edge of the balcony, it should be pointed out that, taking into account the deflection on the main beam on which the cantilever was fixed, there was no deflection of the cantilever registered. As a third test, the whole area of the cantilever portion was loaded with 200lb. per sq. ft., making a total test load of 59 tons, in order to ascertain whether the structure was well balanced. The readings of the deflectors 1 and 2 were 1.4 m/m and 1.5; of 3 and 4 1 and 1.4 m/m respectively; 5 and 6 4.1 and 8.5 m/m respectively. The deflection of the largest cantilever was therefore only 4.4 m/m, or about 1-6th of an inch. When the load was removed, the deflectors went back absolutely to zero.

The fourth test was that of the concert hall floor, which has main beams of 49ft. 9in. span. Each of these four beams was tested separately. The total area of the floor regarded as dependent on the first beam was 23ft. by 49ft. 9ins., or 1,144 sq. ft. The load taken was 200lbs. per sq. ft, making an actual load of 102 tons. Three deflectors were fixed, one being at the centre of the span, giving 4.1 m/m deflection; the other two being each placed 1ft. from the support, and giving 0.2 m/m deflection. The deflection of the beam was therefore 3.9 m/m, and consequently not 1-6th of an inch. In the case of the second, third, and fourth beams, the area of floor tested was 27ft. by 49ft. 9ins., or 1,343 sq. ft., in each case giving a total load of 120 tons on each beam. On the first beam the maximum deflection was 3.8 m/m, and the second 3.3 m/m, in both cases being under 1-6th of an inch. The whole of the deflections registered hardly reached 1-6th of the contract allowance, and the loads applied in the gallery equally 7½ cwt. per seat, each seat occupying the space of 2ft. 9ins. by 1ft. 8ins. The tests must therefore be taken as highly satisfactory.

In carrying out the reconstruction of this building, which involved the complete gutting of the whole structure, the architects (Messrs. Marshall and Tweedy, of Newcastle-on-Tyne and North Shields) made no attempt to cover up the constructional appearance of the work; and the facility with which this type of construction can be adapted to graceful and symmetrical arrangement is shown in the accompanying illustrations.



TYNEMOUTH PALACE. DETAILS OF GIRDER CONSTRUCTION FOR CONCERT HALL FLOOR.
MARSHALL & TWEEDY, ARCHITECTS FOR THE RECONSTRUCTION.

The concert hall floor has main beams of 45ft. 9in. span, constructed in ferro-concrete, and on this being tested, the deflections hardly reached one-sixth of the contract allowance.

Views and Reviews.

Applied Mechanics.*

This book is primarily intended as a text-book for engineering students. The author's idea is that the student finds much difficulty in seeing the applications of theory to practical problems, and to overcome this drawback he has developed each new principle by following the explanatory matters with a number of applications in practice. The problems in this book are thus rightly made to apply to practical engineering work in which not much new matter is included as regards the general principles of the subject, though the author has included a certain amount of new information. For instance, he treats the subject of couples by representing the couples by means of vectors. The chapters on the moment of inertia, centre of gravity, work and energy, friction and impact, it is claimed, are more completely dealt with in theory and application than they are in any other American text-book on the same subject. As these are matters upon which the engineer is frequently in need of information the work is of value to others than students. Professor Hancock has given numerous references throughout the work to original sources of information, and these will be valuable for any detailed study of the subject. Throughout the work free use is made of the calculus, by which principles are explained thoroughly, though shortly, because resort is not had to roundabout methods to demonstrate any subject by other means. The book is chiefly useful for students going through a college course, and it does not strike us quite so favourably as other books which contain fewer examples or problems and a greater amount of practical information, several excellent works on these lines being obtainable.

TYNEMOUTH PALACE. CONSTRUCTION UNDER THE GRAND CIRCLE.
MARSHALL & TWEEDY, ARCHITECTS FOR THE RECONSTRUCTION.

In carrying out the reconstruction, the architects made no attempt to cover up the constructional appearance of the work, which is therefore an object lesson in the facility with which this type of construction can be adapted to symmetrical and graceful arrangement.

Decimal Equivalents.*

No doubt, with our system of weights and measures, whatever advantages it may possess in certain directions, it does not provide so ready a means of performing calculations of addition and subtraction, and often operations of multiplication and division, as a decimal system. Many calculations can be more conveniently performed by converting our weights and measures into decimal equivalents. The metric system is a decimal system, but there is a large amount of opinion distinctly unfavourable to the metric system; still, objection is not so forcibly made to a decimal system in general. To those who have to make many calculations, this book of tables will be found of very great utility, because they have been compiled with the object of removing the only difficulty experienced with our system of weights and measures—namely, that of readily ascertaining the decimal equivalents of any given weight or measure. These tables are arranged so as to show, without any calculation, the equivalents for all the weights and measures in general commercial use in this country, and these are carried through to six places of decimals. It should be sufficient for the most careful work; indeed, for all ordinary purposes, two or three places suffice. For convenience in comparing our weights and measures with those of other countries, the tables of metric and other systems are included in the volume. Engineers will find this table-book of great value, because they often have to use the slide rule and other calculating machines, and such use is to a large extent hampered owing to the difficulty of working in decimals with our system of weights and measures. This book should enable these valuable aids to accuracy and speed in the work of calculation to be adopted more often in English work.

Introductory Statics.*

Students of architecture and civil engineering have more use for statics than for kinematics, and they can, with advantage, take up the subject of statics in books devoted to that one branch of applied mechanics alone. This book is a useful introduction to the subject, for it gives considerable attention to the starting points of the science, and it makes as clear as possible the course of deduction therefrom. It points out the inherent mathematical limitations of pure statics, and shows how all its important problems are solved. It develops algebraic and graphic methods of solution, or, to use other terms, analytical and graphic statics, side by side, and finally presents a graduated series of problems showing how statics may be used in engineering practice. The book is fortunately small in size. The author prefers not to use the terms analytical statics and graphic statics, as he thinks they tend to obscure the unity of the science of statics, whereas they are only two alternative methods of procedure from identical premises. Problems are solved by the two methods in parallel, and in this way the results are checked by the two methods, and the solution of the problem is brought out in a much clearer light. The work is a valuable one as regards the first principles of the subject. Being specially designed for architectural and engineering students, it will especially appeal to our readers. The work is now in its second edition, which has been revised and enlarged.

Chemistry and Physics of Building Materials.*

The student of architecture and building construction is, as a rule, not very scientific in his outlook and attainments. He does not follow very strictly the methods of science. By science we mean not exactly method—which is scientific, at least, in spirit—but the exact or experimental sciences. The building construction student is more practical or more empirical. Rule-of-thumb methods are to a great extent employed; much attention is paid to details of joints in carpentry, methods of laying stones, and so forth, but the general knowledge thus acquired and applied is the outcome more often of tradition than of theoretical deduction. The ordinary building construction student knows far too little about applied mechanics. He is not accustomed to determine the size of members by reference to the laws of stability. He makes few calculations for the strength of the various members by reference to the laws of stability, and our by-laws encourage no scientific study in this direction. Indeed, they are obviously intended for the man who knows nothing of mechanics and very little of mathematics. Knowledge with respect to material is still more hazy. Many civil engineers are just as much at sea. They may have read many books on applied mechanics, but they seldom take the trouble to experiment with the materials and realise exactly what they are. We believe that, in the architecture of the future, scientific training will be appreciated far more than the ability to make pretty drawings. The book under notice represents the first attempt that has been made to give an adequate introduction to the sciences of chemistry, physics, and geology in connection with materials used in building construction. It will be found of as much use to engineers as to architects. In such an introduction as this the author must have found great difficulty in compressing a great mass of information which he would wish to embody. We would gladly have seen each branch of the subject dealt with in greater detail, and perhaps the most formidable criticism we could advance is that the book gives either too little or too much. For a mere introduction to the subject it supplies rather too much detail, for a thorough treatise not enough. Nevertheless, the author produces a great amount of valuable information. The book begins with some general chapters on elementary science. The author says in his preface that his chief object in these chapters is to enable anyone having no knowledge of science whatever to appreciate something of the principles which underlie the subject. As this is all he has set himself to do, we rather grudge the 104 pages—about one-third of the entire volume—which he has devoted to this introduction to elementary science. It would surely have been preferable to cut down this matter to much smaller limits and to devote more space to the subject of building materials. In Part 2 of the work, which deals with these materials, he treats of stones, clays, and cementing materials, metals, timber, and paints. Without criticising the work in detail, we may say that it is not only very free from error, but is well written. It is, in fact, an excellent textbook, in spite of its faulty proportions, which are not confined to the introductory chapters, but are also observable in other parts of the work. For instance, we find over thirty pages devoted to paints, whereas only nine are given to Portland cement. A specialist on any of the various matters contained in the book would probably feel inclined to complain of inadequacy; but it must not be forgotten that the book is not addressed to specialists, and that the author was bound to compress his matter within rather strict limits. As it is, the book is undoubtedly of great value. It is the kind of work for which a distinct need exists. There is room for much scientific work in the demonstration of the scientific principles of many branches of the subject of building construction and structural engineering.

* "Introduction for the Chemistry and Physics of Building Materials," by Alan E. Munby, A.R.I.B.A., F.C.S. London, Archibald Constable and Co., 10, Orange Street, Leicester Square, W.C. Price 6s. net.

The current issue (for July) of "The Architectural Review" has for frontispiece the reproduction of a fine drawing of a portion of the ornate elevation of the library of St. Mark's, Venice. In that extremely useful and no less interesting feature of the "Review" "The Practical Exemplar of Architecture," are included an elevation and measured drawings of details of Wren's fine old doorway at No. 5, King's Bench Walk, Temple, as measured and drawn by Ernst V. West; almshouses, Audley End, measured and drawn by H. A. McQueen; interior views of All Saints', Walsoken, Norfolk, with measured drawings by E. H. Bullock, of the fine rood screen; and a view and measured drawings, again by Ernst V. West, of a gate and piers of the close at Salisbury. Other illustrations show Evelyn's plan for the rebuilding of London after the Great Fire; drawings by Edwin F. Reynolds in illustration of his continued article on "Imperial Mosques of Constantinople"; a view of Professor Beresford Pite's front to Martin's Bank in the Euston Road; an exterior view, an interior, and plans of "Redcourt," Whitfield, Derbyshire (Paul Ogden, architect); views and plans of the Victoria and Albert Museum (Sir Aston Webb, R.A., architect); an exterior and an interior view of the Hammersmith Public Baths (J. Ernest Franck, architect).

TYNEMOUTH PALACE PLANS. MARSHALL AND TWEEDY, ARCHITECTS FOR THE RECONSTRUCTION.

The premises and land of Tynemouth Palace, which is a massive building erected on the high ground of one of the most picturesque portions of the Northumberland coast cover an area of about three acres. In the building as it originally stood (it was intended for an aquarium and winter gardens), the principal department was a large concert hall, with sitting accommodation for more than 2,000 persons, with gallery accommodation for an additional 500. The two rows of iron pillars on which the concert-hall rested have been removed, leaving a clear span of 50ft. in the skating rink. In the gallery also, by the adoption of the cantilever principle, for which reinforced concrete construction affords excellent facilities, pillars to support the tiers have been dispensed with.

SOME COMMON COMPLAINTS OF CEMENT USERS.

The chemical and physical tests of cement are somewhat beyond the scope of the average consumer, who generally depends upon practical results, preferring to watch the action of cement in work rather than to rely upon what results may be shown by laboratory records. This "practical" testing, however, is far more likely to give erratic results as to the qualities of cements, and with far more serious consequences, than any recognised theoretical tests, for there are innumerable ways in which a cement of perfectly satisfactory quality may, by faulty manipulation, be made to appear otherwise; and, again, there are many aggregates which destroy the otherwise sound qualities of really faultless cements.

The practical test is often "the parting of the ways" between manufacturer and consumer. As well as being extremely unscientific, this test is fair to neither one nor the other, and in the event of unsatisfactory concrete work resulting, two diametrically opposed courses are adopted by the cement maker and the purchaser, the one contending that he is only responsible for the quality of his cement, and the other that he is not responsible for any faulty work carried out with the cement he purchases.

The position that thus arises can generally be settled to the satisfaction of both parties by the exercise of a little intelligent interest and labour in investigation, and far more often can the causes of faulty work or the failure of a cement in a practical test be truly ascribed to faulty use rather than to inferior cement. The manufacturer often safeguards his position by having samples of the alleged faulty cement tested to the recognised standard of quality or specification, and there he considers his responsibility ends. This attitude may perhaps be admitted to be just, but the cement maker, in addition, should exercise his skill in further explaining to the consumer in what points "practical" test may have been fallible, if only in vindication of the status of his manufacture.

For instance, the cement maker will find it to his advantage to assist his customers down to the smallest detail of the work, so far as he is able. They will appreciate his efforts, and will prefer to purchase from him on account of the additional services he renders to them.

This may appear at first sight to be a weak argument, the customer being given information for which no consideration is received in return. In practice, however, such assistance to customers brings good financial returns, because the maker is able to exercise a certain amount of control over the way in which his product is used, and to maintain the reputation of his cement at a higher level than would otherwise be the case.

In most complaints of faulty cement nowadays there is perhaps more truth in the assertion that "poor workmen always blame their tools" than in the quality of the "tools" brought into account. Many complaints compare only with the case of the cook who excuses heavy cakes by blaming the flour.

Portland cement, however superior its quality, can never give satisfactory results unless properly dealt with, and, being the perfectly scientific product that it is, the number of ready methods by which the best quality of cements can be easily made to give unsatisfactory results is legion.

Primarily there is the difficulty of obtaining efficient supervision in concrete constructional work; for little interest is shown by workmen in so dreary an occupation as filling concrete into wood troughs, and, moreover, ordinary labourers have, as a rule, preconceived notions on the subject which are with difficulty got rid of.

As to cement, after the endless stream of information, investigation, and discussion upon Portland cement—its manufacture, testing, and uses—the ignorance of workmen is deplorable—not, of course, those in charge of concrete works, but the workmen under supervision, whose every movement must be closely watched. So long as cement is thus used or misused, so long will there be defects in concrete construction to be investigated.

It is not sufficient, therefore, for the cement maker to produce first-class cement unless he exercises some care that it is supplied only to people who will use it properly, and not bring discredit on the maker by ignorance or carelessness.

In describing, then, more fully, some unjustifiable conditions in regard to the use of cement, a few instructions are here submitted as to the way cements should be employed to give the best results.

It is remarkable what a consensus of opinion prevails among cement consumers as to the cause of *any* fault in concrete constructional work. It is *always* the cement!

Complaints are either justified or they are not, and in the latter case the species of unjustifiable complaints can be classified under certain definite headings, such as from the result of (a) prejudice, bias, or sentiment; (b) experience, or ignorance; (c) malice or motive; and (d) chronic dissatisfaction, which seems to depend upon some physical state—say, torpid liver, or some such "common complaint."

With the present-day scientific manufacture of Portland cement, few complaints as to quality are really justifiable. It is, indeed, certain that if any Portland cement passes the British Standard specification tests, no amount of complaining or investigation could show that such a cement would be the cause of any unsatisfactory work when properly incorporated in concrete. The bulk of complaints, therefore, it will often be found, come under one or other of the above headings.

As to the first cause of complaint or dissatisfaction, all intelligent persons have a found of distinct likes and dislikes in colour, form, proportion, quality, etc. In the same way, many cement users have distinct preferences for particular brands of cement, and if they cannot obtain their favourite brands, then the substitute is not to their satisfaction, and the seller of the substitute is likely to hear of it.

As to the second species, if the cement is good, what matters it to them if the cement is mixed with any sort of material, provided it is obtainable at a sufficiently low price? Certainly there is a specification for aggregates, but it often happens that very little attention is paid to it. The result is that occasionally some apparently unaccountable failure occurs, which is always—and seldom with justice—attributed to the cement. Most of such failures can be proved to be due to lack of knowledge on the part of the workman and to unsuitability of the aggregate. Chalk, coal, and lump lime have been found in samples of concrete which have either actually failed or have been so unsuitable that a complaint has been the result. No just-minded consumer could expect concrete in which chalk was the aggregate to be mechanically strong; yet users of such an aggregate do not hesitate to condemn the cement.

As to complaints that arise from mere malice or motive, perhaps the less said the better, but since it is a fact that complaints are often known to arise under these conditions, they must of necessity be mentioned in this article. Under this heading might be included the case of the complainant who tries to obtain extended credit or evade the payment of his account by calling into question the quality of the product long after it has been used.

Where a complaint is the result of torpid liver, the party who gives way to such physical attacks is an odd but nevertheless strenuous grumbler, and is to be dealt with firmly but kindly.

It must therefore be conceded that in numerous ways cement work may prove unsatisfactory from causes which are altogether beyond prevention by the manufacturer, and have no relation whatever to the quality of the cement. Probably the most common cause of trouble is the failure to recognise the fact that the setting of Portland cement is a chemical process which may easily be retarded or destroyed by unfavourable conditions or interference. Care, experience, and supervision are always necessary in the use of cement, and it is poor consolation for loss of time and money to throw the blame for faulty work on the manufacturer. He now works on much more scientific lines than formerly, and can generally make out a strong case for the defence where necessary. The ways in which cement work may be spoilt by the user are too numerous to enumerate fully, but the following illustrate some ways in which this very undesirable position may be attained:—

(a) The use of too much or too little water during mixing, or water carelessly applied, or water containing earthy matter, clay, or loam.

(b) The use of an insufficiently graded aggregate, and one containing only very coarse material, or one with too much sand or loam.

(c) By not thoroughly incorporating the aggregate with the cement; by allowing the concrete to stand until the setting action has commenced, and then regauging before use. By rendering cement work on dry foundations and without thoroughly saturating the surface with water.

(d) By using a dirty aggregate.

The cement user needs to know, first of all, what he really wants in a cement—that is, what properties are of special value in his work. With this knowledge will come a better realisation of the necessity not only for uniform methods, but what is more to the point—uniform tests. When he realises that because one brand does not harden quite so rapidly as another it is not necessarily inferior for the average piece of work; and that the cement which fails to gain 12 or 15 per cent. over 900lb. from seven to twenty-eight days is not likely to suffer by comparison with average cements in any other way; that when properly made and seasoned these cements are equally good for most ordinary work (although one or other may be superior for some special work); when these facts are generally understood and appreciated, there will be no reason for a manufacturer to modify his test methods so as to make a given showing—to obtain predetermined results—and uniform tests will be advanced a long way, and the manufacturer will be the first to hail such a condition of things with satisfaction.

Now this position necessitates an extremely careful study in the testing and uses of cements when the same are employed in concrete work, both in the mixing with water and more especially with the choosing and mixing of aggregates and the handling of the concrete.

At the new Military Families' Hospital, Shorncliffe, which was opened recently by H.R.H. Princess Christian, for H.M. War Department, Messrs. J. F. Phillips and Son, heating engineers, of 21, Old Queen Street, Westminster, and Brighton and Liverpool, carried out the heating apparatus and domestic water supplies.

* * *

The decay of the stonework at Westminster Abbey proceeds with alarming rapidity. Dr. John Owens states that "repairs executed only twenty or twenty-five years ago are decaying more or less; that work executed only fourteen years ago is in a bad state; and that that done in 1701 shows signs of being reduced to a friable mass to a considerable depth below the surface." Mr. Edward Hull recommends, in substitution for the fine granular or oolitic limestone of the Jurassic formation that has been used, the building stone of the New Red Sandstone formation, to be found in Stafford, Salop, and Cheshire.

A REINFORCED CONCRETE CONDUIT.

We give in this issue some illustrations of work done in 1909 in connection with the water supply of San Paulo, Brazil. In this work a great amount of reinforced concrete was used, and the construction is of a very interesting nature. The scheme was prepared by Mr. L. Betin Paes Leme, the Government engineer of Brazil, and was carried out under the supervision of Mr. Henry Schulman, engineer to the Companhia Mechanica e Importadora de S. Paulo, who constructed and completed the work in ten months.

The two reservoirs are each 56 metres by 39 metres by 4 metres, or 183ft. 8ins. by 127ft. 11ins. by 13ft. 1½ins. in size, and each stores 6,000,000 litres or 1,321,000 gallons of water.

The aqueduct is 12,000 metres, or 39,370ft. long, and the pressure pipes are 4,000 metres or 13,125ft. long, the latter being 1.20 metres or 4ft. inside diameter, and 1.37 metres or 4ft. 6ins. outside diameter, and withstand a maximum pressure of 30 metres or 98ft. 6ins. head of water, the line carrying 500 litres or 110 gallons of water per second.

The pressure pipes, as well as the aqueduct, were constructed in continuous lengths. No. 8, 3-in. mesh, ¼in. by ⅛in. (bare) strands expanded steel of British manufacture was used throughout for the aqueduct. Expanded steel sheets were favoured for reinforcing the concrete, because they did not require skilled workmanship, which was not easily obtained in Brazil.

Reinforced concrete is a particularly valuable system of construction of such work as, owing to the difficulties of transport, only the concrete and cement need be transported.

We give three views showing the work in course of construction, and we would draw particular attention to the construction of the aqueduct by means of a centering of wooden ribs. These ribs were used over and over again, and were easily fixed in position. In a sunny climate, and a country also subjected to torrential rains, a roof over the work was necessary, and our view shows a movable roof that was used as a protection against the weather during the construction.

In constructing the aqueduct through tunnels the top section was moulded separately, and the work was not done *in situ*, except the bottom of the aquehduct, and the fixing of the top section thereto.

Temporary timbering had to be used on the outside of the aqueduct as well as an inner core of centering, this being shown in one of the views.

The reservoir was constructed with cast-iron columns, carrying rolled-steel joists, upon which expanded metal was placed to form a reinforced concrete roof. The floor was also reinforced with expanded metal and round steel rods. The division wall of the reservoir was reinforced with expanded metal.

Some tests were conducted in the preliminary stages of the work upon the resistance of pipes to pressure, and sections were heavily loaded on the top to test their resistance to a superimposed load of earth. The ends of the section were also sealed by large plates, and hydraulic pressure was applied to test their permeability.

We have not the results of these experiments before us, but we are informed that the results were eminently satisfactory, which is substantiated by the fact that after these preliminary trials the work was ordered to be proceeded with.

Reinforced concrete would seem to have entered upon an almost limited field of utility; and the present instance demonstrates very strikingly its ready adaptability to engineering works and methods.

Our Plate.

This shows some measured drawings of the Church of St. Alfege, Greenwich, by Mr. Frank A. Collard. St. Alfege is attributed to Nicholas Hawksmoor, a pupil of Sir Christopher Wren, and clerk of works under him at Greenwich Hospital. In this office he was succeeded by John James, who is reputed to have designed the tower of this church. We shall publish some further drawings by Mr. Collard next week.

Builders' Notes.

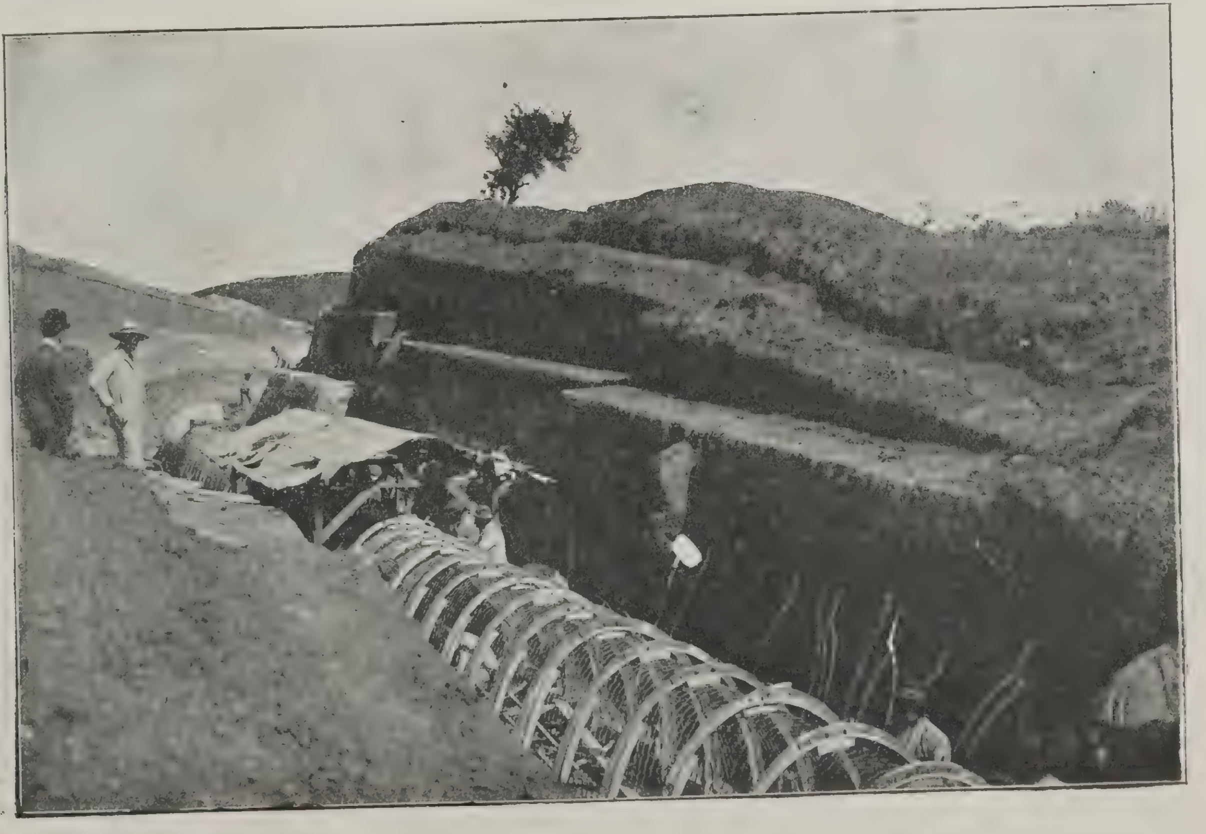
The Cork Master Builders' Association have asked, individually, the unskilled labourers in their employment if they were willing to sign the following declaration:—"We, the undersigned, are willing to obey our employer's orders, and are prepared to go to any establishment in the city where we may be sent on our employer's business." Those who declined to sign were instantly dismissed.

* * *

Leeds Master Builders' Association have had under discussion the provisions in the Housing and Town-Planning Bill that prohibit the erection of back-to-back houses. The opinion generally expressed was that the common strictures on back-to-back houses are not applicable to the style and character of such dwellings as erected in Leeds, and several members urged that it would be disastrous if any hindrance to the erection of dwellings at a reasonable cost were imposed in towns where land is freehold, as rents are necessarily based on the capital invested in the purchase of the land, as well as in the erection of the buildings. Members said that they were unaware of any town in England where the working classes are so cheaply and so efficiently housed as in Leeds. It was resolved to support the Corporation's opposition to these clauses in the Bill.

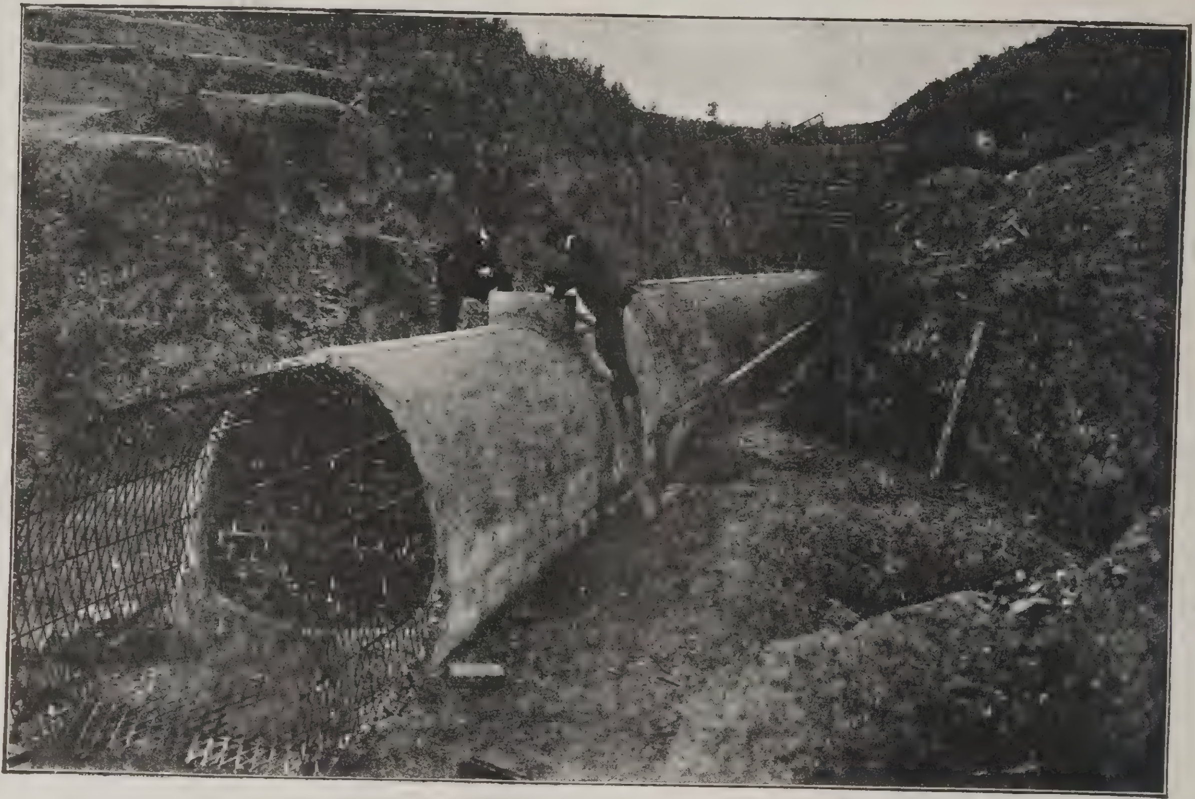
REINFORCED CONCRETE LINTELS.

Artificial stone lintels have been made by builders and others for many years past, and in these lintels, which were really concrete though known as artificial stone, some form of reinforcement or strengthening by the inclusion of steel or iron sections was necessary. The form favoured by builders was to use old bedstead rails or gas-barrel, and in some cases small joists. This iron was placed in the lintels without any real regard to its proper position, and the principles of reinforcing these beams—which in reality they were—were not understood, so that the metal was employed very wastefully. Now that the principles of the reinforced concrete are better known, we find



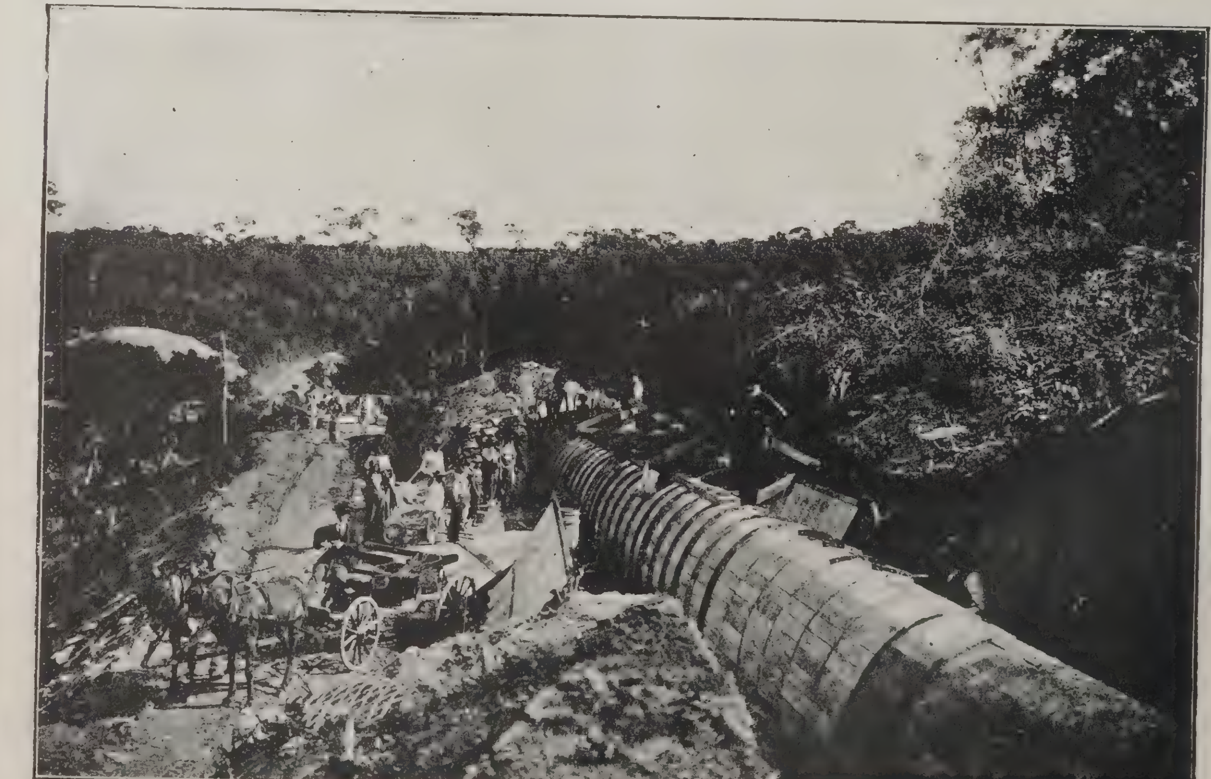
A REINFORCED CONCRETE CONDUIT. SHAPED RIBS FOR TIMBERING.

In constructing this aqueduct, temporary timbering had to be used on the outside, as well as an inner core of centering, and the illustration shows the shaped ribs carrying the timbering. In a sunny climate, subject to torrential rains, such protection is very necessary.



A REINFORCED CONCRETE CONDUIT. MANHOLE.

The view shows a manhole or inspection chamber in the conduit and is very suggestive of the ease with which the system can be adapted to such services.



A REINFORCED CONCRETE CONDUIT. RIBS CARRYING TIMBERING.

On page 53 is a view showing the ribs prepared to receive the external temporary timbering. The present view shows the timbering in position.

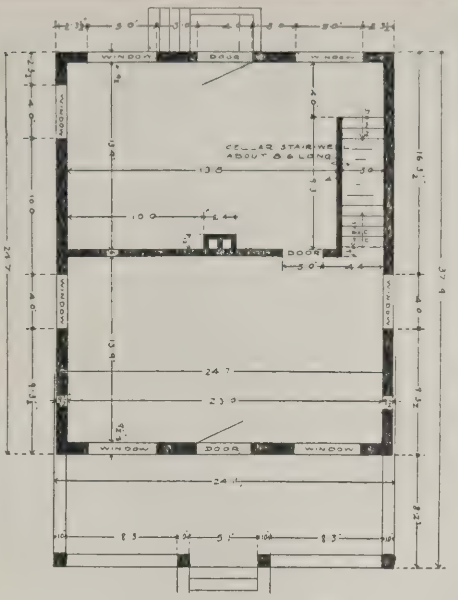
these lintels constructed in a more scientific manner. The Trussed Concrete Steel Company, of Caxton House, Westminster, are alive to the fact that those who make these concrete lintels now begin to appreciate the proper principles upon which to construct a lintel, and they have issued a small catalogue having special reference to the use of the Kahn trussed bars for the reinforcement of lintels. This pamphlet shows how considerable economy is obtained over the old methods of construction by the use of Kahn bars, and a table is provided to show exactly how to apply the reinforcement, the sizes and quantities for lintels with a varying span from 3ft. to 20ft., and carrying loads from two tons to thirteen tons, as also the price of the reinforcement per lintel in each case. This is a valuable table, and will be found of considerable service to those who require to execute such work.

THE EDISON POURED HOUSE.

The Edison poured cement house has been, ever since the announcement of its inception, a stock topic for the alleged humorist. It has supplied him with moulds into which to pour his favourite mixture of ridicule and contempt. To think that ridicule and contempt cannot kill must be tolerably hardy; and Mr. Edison's invention has evidently survived the ordeal, and also that of the indiscriminate praise of such as believe that Mr. Edison's genius cannot err. There were also genuine philosophic doubts as to the practicability of the system. It was supposed that cement would clog when an attempt was made to pour it into intricate moulds; and horror at the idea of a city full of houses, each a fac-simile of the others, was expressed very freely and feelingly.

Mr. Edison, it appears, has anticipated or met these objections. He has produced a mixture that will flow freely into the moulds, and yet will allow of a uniform distribution of the aggregates. Moreover, change of style with the same set of moulds can be arranged; and by the use of half a dozen sets of moulds a wide variety of style is possible.



THE EDISON POURED HOUSE. GROUND PLAN.

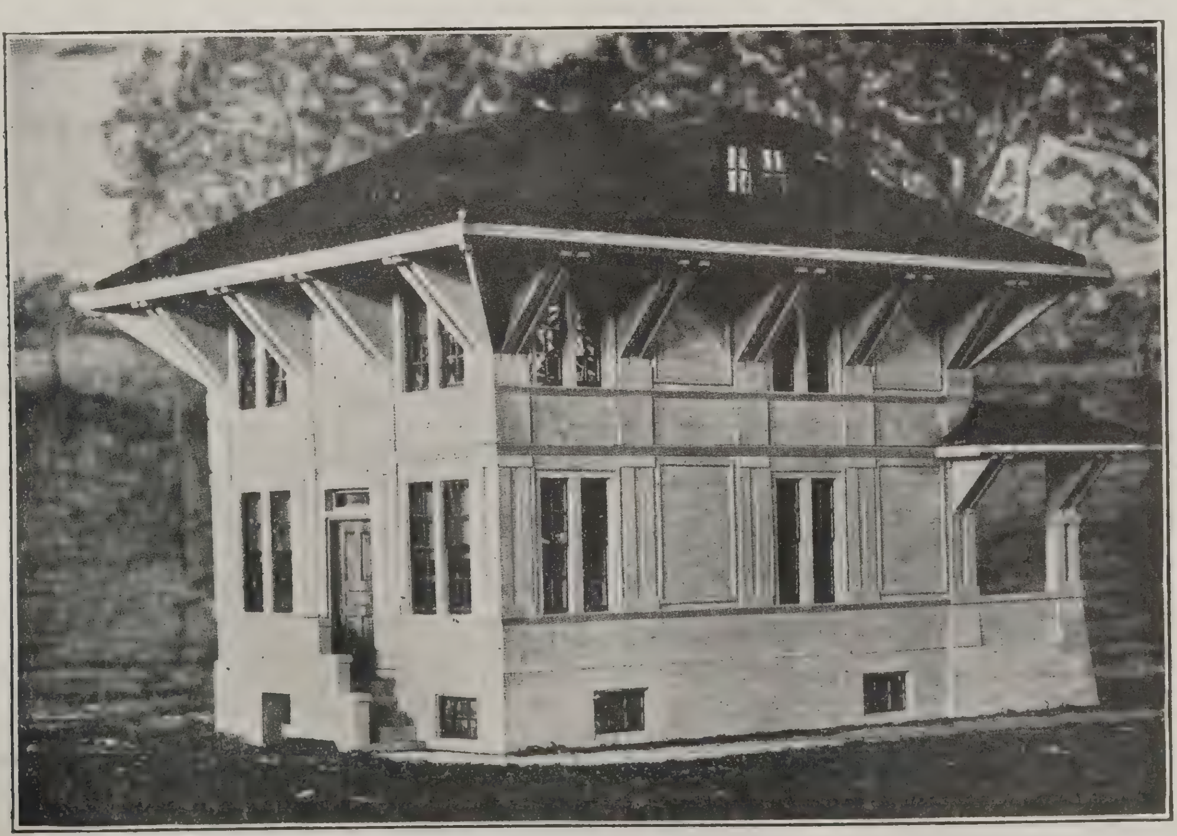
There are two bedrooms and a bath-room on the first floor and two bedrooms in the attic.

The moulds are of cast iron, about an inch thick, and are, of course, assembled and locked together for the pouring. Mr. Edison at first conceived the idea of a two-family house; but he now thinks that a one-family house would be preferable. Such houses, it is estimated, can, if the materials are bought in large quantities, be constructed at a cost of 1,200 dollars. The house would have a floor plan 25ft. by 30ft., and is intended to be built on lots 40ft. by 60ft., so as to give a fair amount of garden room. The front porch extends 8ft., and the back porch 3ft. On the first floor the front room will be 14ft. by 23ft. by 9½ft. high, and is meant for a living-room; a kitchen in the back being 14ft. by 20ft. by 9½ft. high. The second floor will contain two bedrooms, a wide hall, and a bathroom 7ft. 6ins. by 7ft. 6ins. by 8ft. 2ins. high. The cellar, 7ft. 6ins., extends under the whole house, and will contain the boiler, wash-tubs, and coal-bunker. The main room, as well as the outside of the house, will be "richly decorated," the decorations being cast as an integral part of the structure. The house, in fact, will be monolithic, and there will be no plastering, the surface left by the moulds being perfectly smooth, and capable of taking paint.

In constructing the house, the first step is to prepare a concrete foundation or footing, which, with the basement floor, must be thoroughly set before the moulds are placed in position. Regulation reinforcing rods can be used in the moulds, and all gaspipes, etc., are placed in position when the moulds are set up. The erection of the moulds will take about four days, but the pouring of the liquid will occupy no more than six hours. Four days after the pouring, the dismantling can be done, and six days more are allowed for the hardening of the concrete. A house, therefore, can be completed in about fourteen days.

Mixers of extra-large size will be used, and the concrete, after being mixed, will be placed in large tanks, from which it will be conveyed to a distributing tank on the roof or top of the forms. Numerous open troughs or pipes will conduct the mixture to various openings in the roofs, whence it will flow down and fill all parts of the moulds to the footings in the basement, until it overflows at the top of the roof. As the pouring proceeds, the mixture is agitated to prevent congestion of the materials. The great feature of the invention is the composition of the liquid, which, while it flows like water, and fills all interstices, is nevertheless a true concrete. A complete set of moulds will cost about 25,000 dollars, and the necessary plant will increase the expense by 15,000 dollars.

Mr. Edison's assistants in the exhaustive experiments—covering a period of eight years or so—are Mr. George E. Small, from Philadelphia, and Mr. Henry J. Harmes, who was formerly in the service of the British Government in India.



THE EDISON POURED HOUSE.

Mr. Edison claims that he has produced a mixture which, while flowing freely into the moulds, will allow of a uniform distribution of the aggregate. The depth of the overhanging eaves is perhaps necessitated by the arrangements for pouring.

PRACTICAL CONCRETING.

Matrix and Aggregate.

Architects and engineers have long recognised the importance of good quality in the concrete used in all constructional work, and stringent specifications are often met with dealing with the class of matrix and aggregate to be employed, and the proportions in which these are to be gauged. Clerks of works, who really are the inspectors of the quality of materials to be used, are bound to be particular in their supervision under such conditions; and, in fact, it is not uncommon for contractors to complain that some clerks of works are more exacting in their requirements than the specification warrants; too often, it is whispered, because the clerk of works is young and inexperienced, and hopes to please the architect by a show of zeal.

Disregarding, however, the personality of the clerk of works or inspector, there is no doubt that one of the most important items requiring constant supervision is concrete making and placing, no matter what position it is to occupy in the work, nor is there any doubt that an incomplete or a faulty specification for concrete work is a curse to the contractor and the architect alike, as it gives, on the one hand, opportunities to the unscrupulous contractor to scamp his work, and on the other, affords an exacting clerk of the works opportunities to worry a conscientious builder unnecessarily.

A word first, therefore, on the materials forming the concrete. If the matrix, or cementing material, is specified of standard quality, it is all that can be desired. As regards the aggregate materials, the architect's specification should be exact as to their requirements.

Cement Specifications (Normal).

A clerk of works would be perfectly certain to get from the contractor all the architect could desire, if the whole of the cement used on the works were required to be "best, highly-burnt, pure Portland cement, to conform exactly to the terms of the British Standard specification."

With such a cement, properly employed, no unsatisfactory work could result.

Extra Precautions.

But if any extra precautions are deemed advisable for specially important work, the contractor should be required to provide at some convenient part of the site a suitable shed, or other approved building, having a damp-proof floor, with all necessary subdivisions, so that each consignment of cement may be kept separate; the shed being of sufficient size to contain such quantity as the architect or clerk of works may order to be kept in store.

All cement before being used should be spread upon this floor in a layer not exceeding 12ins. in thickness, and allowed to remain at least 14 days, or for a longer period if the condition of the cement requires it, the contents of the various bags or casks being thoroughly mixed with each other in spreading out on the floor, and the cement should be turned over from time to time as the clerk of works may direct.

The contractor should take precautions to keep all cement dry, and provide all necessary waterproof sheeting or tarpaulins for the protection of the same on the works.

The contractor should always keep sufficient stock for 14 days' requirements at least, and, with each delivery of cement, he should be required to furnish the architect or clerk of works, in writing, particulars of the quantity sent in, the maker's name, the date when taken from the kiln, and have samples taken from the consignment, in the presence of the representative of the architect, for testing purposes, and deliver the same at the office of the latter, properly marked and labelled.

The cement should be tested by the architect, and all that fails to comply with the above-mentioned standard should be rejected and forthwith removed from the site at the expense of the contractor. An average of three briquettes should be considered conclusive. No cement should be used until after being tested.

This is the one I prefer — E

THE EDISON POURED HOUSE. DECORATIVE DETAIL.

This is Mr. Edison's favourite decorative design.

The first consignment of cement should be put in store immediately after the signing of the contract for the purpose of testing, and the architect and clerk of works should have free access to the store at all times, and be at liberty to take samples of cement when they might desire.

But no matter how exactly a specification is written concerning the materials, inferior concrete may result from bad workmanship in the making, mixing, depositing, ramming, etc., all of which faults could be avoided with proper care and supervision.

Aggregate Specifications.

As to the aggregate, the specification should demand a perfectly clean and hard material, one readily obtainable and near the site of the work, and graded in size according to the bulk and character of the work in hand. If the specification is vague on the point of the materials, and the clerk of works is to be the arbiter of the quality of those supplied, it is not at all unilkely that grave injustice may be done to the contractor, or that some very peculiar substances may be brought on the site for aggregate. On one occasion, when visiting an important concreting job, we arrived in time to see four yard-cart loads of old pantiles brought to the site as aggregate for concrete. The contractor evidently had some buildings to demolish close by, and rather than cart the waste materials away to a tip, had hoped to utilise them on his neighbouring job for the purpose mentioned. They were black with age, covered with soot, moss, and even small fibrous roots. The only point in their favour for the purpose the contractor had in view was their hardness, but otherwise their dirty condition and similarity of shape (even when broken up to pass the specified gauge) was sufficient reason to reject them out of hand. Old drain pipes, slimy when wetted; old bricks, previously used for flues and coated thickly with soot; and old concrete, made originally of weak lime, and now crumbling at the touch, are some of the materials brought forward as substitutes for good ballast, etc., and if the clerk of works is inexperienced, and the specification weak or vague, such materials may find their way into the new work, to the detriment of its stability.

Aggregates: Various Non-absorbent Materials.

When the proportion of the cement is low, aggregates of a non-absorbent character make better concrete than pervious ones. River gravel, when obtained from sluggish streams, has often fine muddy clay, washed in from the banks, attached thereto. This should be eliminated by washing. Thames ballast, for instance, is not always of one character, as every London builder knows. It depends from what part of the river it is obtained.

Old tiles, slates, and similar materials, are unfit for aggregate for concrete. They are unshapable, and impregnated with smoke and impurities.

Clay, if thoroughly and uniformly burnt, is a good aggregate. Much depends upon the quality of the clay, and the skill of the burner, but in all cases it is one of those aggregates that require washing, as it is as a rule covered with a film of impalpable dust, and, moreover, has to be screened or broken to a suitable size.

Old bricks from buildings in course of demolition make good concrete if broken with a crusher, but not if handled, while if smoky and soot-laden, they should only be used in foundations. If used for walls, floors, or ceilings, where the latter are formed by plastering direct on the concrete, stains will inevitably appear in course of time.

Slag.

Slag, unless it has been allowed time for aeration by exposure to the atmosphere for a year at least to get rid of the sulphur it contains, will disintegrate the concrete; failures have happened from using slag not sufficiently aerated, otherwise it is a good aggregate.

Thames Ballast and Coal.

Thames ballast and sand often contain pieces of coal which may have been thrown overboard, or in some other way got mixed therewith. In such cases the aggregate is extremely unsatisfactory for concreting purposes, as the coal is bound to expand and disintegrate sooner or later.

Size.

To obtain the greatest resistance in concrete it is advisable to increase as much as possible the size of the aggregate and sift out the finer grains. The largest aggregate makes the densest concrete; an aggregate having a maximum diameter of 2¼ins. proved to be denser than an aggregate of 1in. maximum diameter. This result is just the reverse to what has been taken for granted ever since concrete has come into general use. Again, permeability is less as the maximum size of the aggregate is greater; concrete with a maximum size aggregate of 2¼ ins. diameter, is in general less permeable than with a 1in. maximum diameter, and 1in. maximum less permeable than ½in. These results were arrived at from a large number of experiments, and are opposed to all theory, another proof that theoretical deductions in matters dealing with concrete must be received with caution.

Cleanliness.

Clean, and preferably washed, aggregate is essential for satisfactory concrete. The materials may not under any conditions be dirty in themselves, in the sense of fitness for an aggregrate, but all materials that have been crushed by a machine, broken by hand, or passed through fire, are covered with a film of impalpable dust, which is harmful to cement. The value of Portland cement is much lessened by coming in contact with deleterious substances, much more so than lime; dust is one of them, and fine sand or grit is another.

A dirty sand with a rounded grain, and containing clay or earthy matter, is still another undesirable aggregate.

In the washing of brick *debris* as an aggregate, there will be noticed a thick red pasty mass containing nothing that is necessary to retain in the aggregate, but much that is harmful in concrete work made with such a material.

Avoid Proximity of Lime.

Some aggregates, conveyed by rail, have been placed in trucks used for the conveyance of lime, portions of which have got intermixed therewith, and, being unnoticed, have caused the concrete to blow or burst. The aggregate for concrete should not be deposited near a lime shed, nor where plasterers are running lime for plastering, as pieces of unslaked lime or lime core may inadvertently find their way among the concrete material. Numerous failures have occurred through pieces of lias limestone having passed through the furnaces of locomotives and got mixed with the ashes, which were afterwards used for making concrete. In one case a large flight of concrete stairs and floors was completely wrecked as a result of this.

Sand Should be Selected.

The sand should be carefully selected for the purpose, as all kinds are not equally suitable. It should be highly silicious, and of sharp angular grain, and if contaminated with clay or soil must be well washed before use. If the mixture is to be specially waterproof the sand particles should be 1-75th to 1-25th ins. in diameter for the facing and 1-25th to 1-6th ins. for the filling, when the cement is used for thin walled vessels. If the walls are over 2½ins. thick coarser aggregates, with particles up to ½in. diameter, may be used. Even then they should be as angular as possible, and of such sizes as to fit as closely together as possible, with a minimum of voids, in order to produce a perfectly waterproof mass.

5.—Proportioning of Ingredients.

One of the most important points in concrete making is the proper proportioning of the ingredients. The particular proportions should be defined in the specification, and for this purpose proper gauging or measuring-boxes must be brought into use. The capacity of the one for measuring the cement will be proportional to the volume of the aggregate to be used, and is best made with a bottom to it, so that the cement may be placed on top of the aggregate after measurement. That the boxes are of the correct capacities the clerk of works will have beforehand determined for himself. The supervision of concrete must be constant, for which reason the mixing should take place in full view from the window of the clerk of works' office; if this is impossible, the clerk of works should be always outside whilst the mixing is taking place. and at this time the hours of the clerk of works should be those of the workmen.

(To be concluded.)

CONTRACTORS' USE OF COAL: A SCIENTIFIC SYSTEM OF BUYING.

By a Contractor.

(Concluded from page 34, No. 753.)

Method of Payment by Results.

The results of experience thus far set out seemed to demand some simple and practical method whereby uniformity of steam raising value could be obtained. Reference to the results of testing various consignments, shown in Table A, establish that 70 B.T.U. per penny of cost per ton was a reasonable basis for future orders. Table B shows the results of orders thus placed. Various coal merchants were given the option of supplying any coal they like at costs ranging from 13s. 9d. to 15s. per ton, including delivery. In the case of coal L., the delivery price of which was 13s. 8d., the number of units stipulated were 11,480 (this figure is arrived at by multiplying 70 by 164, the number of pence in 13s. 8d.). The order provided that 1d. would be deducted from the cost per ton for every 70 units less than, or 1d. per ton added for every 70 units more than 11,480. The consignment thus supplied to this order proved on test to afford 11,700 units—*i.e.*, 220 in excess of the stipulated amount. The merchant therefore received an extra of 3d. per ton on the basis price. In the case of coal M, costing 14s. 10d. per ton, the number of units stipulated was 12,460. The units ascertained on test amounted to 12,263, and 3d. per ton deducted was from the invoice. The table shows other results of a varying kind.

As the coal market rises and falls, the basis of units per penny will rise and fall, but many contractors make periodic contracts at a fixed price, so the basis needs to be reconsidered only at fixed intervals.

It is to be remembered, of course, that the 70 B.T.U. per penny refer only to the contract under review. Each contract must be taken on its own merits, and a fair basis reached by experiment on two or more coals. Once started, however, the system becomes automatic, and gives no more extra labour than if buying were done in the old way.

Sampling for Tests.

It is clear that where the price paid is calculated on the number of B.T.U.'s established by test, it is of great importance both to buyer and seller that the sample tested shall be a perfectly fair one. In America the importance of paying on test is so largely recognised and employed that there exists, in the Fuel Engineering Co., of Chicago, an undertaking which samples and tests on behalf of both buyer and seller, and the report of this company is accepted by both as final. There is little doubt that some such organisation will come into being in England when the obvious fairness of this method of purchase becomes more generally recognised. Meanwhile, there are two methods which can be adopted: (1) that the representatives of the buyer and seller shall meet at the point of delivery and select a fair sample, and shall despatch it direct to the testing laboratory; or (2) that the buyer and seller shall jointly instruct the testing laboratory to send a representative to take a sample. The former should be quite satisfactory, but the latter removes any possibility of dispute, and its only disadvantage lies in the increased cost of testing. There is, of course, the third method, that the seller should rely on the honesty of the purchaser to select a fair sample, and this has been the method employed in the purchases described in this article. Such a method, however, can only be employed where the seller has perfect confidence in the uprightness of his customer. Ten pounds of coal is the ordinary amount sent to a testing laboratory, and this should be made up of small pieces of coal taken from different trucks (if it be railborne), and from different parts of the barge (if it be water-borne), and the different pieces should be taken from the top, middle, and bottom of the truck or barge. A handful of slack should be added of the same proportion to the large coal, as is the case with the whole delivery. The testing is done with Thompson's calorimeter, and it is important that the work should be carried out by thoroughly experienced men, in a laboratory of high repute. The tests described in this article have all been carried out at the testing works of an inspecting engineer, who works for several Government departments, and whose competence and impartiality are beyond dispute. There are, however, many other laboratories of high repute, any of which will undertake the work.

Cost of Testing.

It is often alleged by the practical man, who is suspicious of the undue intrusion of science into commerce, that the cost of scientific tests is greater than is warranted by the value of the results. Such a case, however, cannot be made out against coal-testing. The cost of a test for moisture, ash, and calorific value is only one guinea per sample. If one sample be taken on every 100 tons, the cost is about 2½d. per ton.

Cash Saving Secured by Scientific Buying

When all is said, the merits of any new business method must be measured by the actual saving of money which results. This article sets forth the results of a contractor's experience in respect of coal-buying for one contract only, where the consumption of coal is about 100 tons per week. Buying was done in the early stage of the contract in the ordinary way, by selecting coals which had been bought before, and which are habitually used by well-known contractors, whose judgment in such matters ought to be sound. When the practical man on the works spoke well of the coal so bought, there seemed every reason to be satisfied that the full value was being obtained. However, by experimenting with a variety of other coals, and gradually eliminating those which gave a low value in B.T.U. per penny per ton, and by establishing a standard of B.T.U. below which the coal must not fall, a saving of £10 per week has been effected. This saving, considered in relation to the value and duration of the contract, amounts to one per cent. on the gross value of the contract. To achieve such a result on a single item of the varied channels of expenditure seems well worth the very little time and trouble which is involved in buying coal in a scientific way.

As coal merchants come to see the essential fairness of this method of purchase, there is no doubt that there will be competition to secure orders by offers to buy on a higher basis of B.T.U., and the saving on the present method of buying will be proportionately increased. As it is thought that other contractors may like to follow the example of the firm whose experiences are recorded above, the Editor will be pleased to answer questions in these columns and to put contractors in the way of reorganising their coal-buying on an economical basis.

TABLE A.

Results of tests taken on various representative coals, to enable purchaser to establish number of British Thermal Units per penny per ton, which should be obtained and fixed as the basis for future contracts and payments.

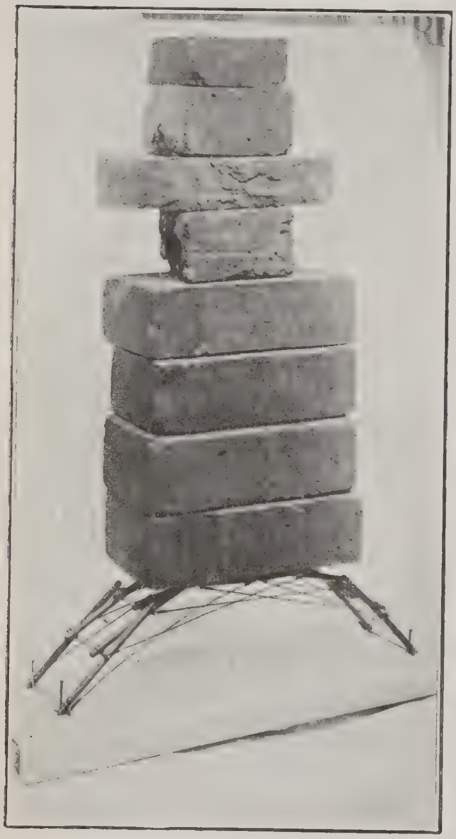
P (average of 3 tests on large shipment)	11·91	4·38	11,857	14/9	12,390 (177×70)	−533	−7½d.

A TRANSPORTABLE BRIDGE.

We have received some particulars of a system of bridge construction which has been devised by Mr. Reginald C. Fry, architect, of 12, Clifford's Inn, E.C. This system, which has been provisionally patented, is decidedly ingenious. The proposal is to build up a bridge by means of standard bars consisting of compressional members, tie-rods, and cross-bars. These are used for the construction either of trussed girders or of trussed arches. The connections of the standard pieces consist of holes in the compression members in which the cross-bars are inserted, and the eyes of the ties are placed on the ends of these cross pieces. Certainly models show that a bridge or girder can be constructed very quickly by the use of such standard members. The cross-bars are prevented from slipping out by the insertion of small pins, but there is apparent the lack of rigidity which might be expected where riveting is not employed. Therefore the system loses the advantages attributable to rigid connection. Certainly Mr. Fry's idea could be used for the construction of a bridge such as might be required by soldiers, as it is very quickly built up, while the standard pieces could certainly be easily transported. Mr. Fry advocates the adoption of his system for War Office purposes. On the face of it the system seems to have advantages. Though the transport would not be particularly difficult, at the same time the standard sections would be heavy to handle, and standard timbers would be preferable. His standard sections do not seem to us to be economical of material. We refer more particularly to the compression members, almost half the weight of which is wasted theoretically, having regard to the amount of metal required to meet the stresses imposed, while in the form of arch construction proposed there is very little rigidity in a large span.



Mr. Fry suggests the use of this system of construction for the purposes of forming a centreing for the construction of concrete or reinforced concrete arched bridges, the idea being that these standard bars might be stocked by a contractor.

Mr. Fry has issued a small descriptive pamphlet which makes many claims for the system, but we should like to see practical proof of the advantages. Certainly the models that have been built on Mr. Fry's principle show considerable strength, but if they are analysed it will be seen that the strength is not really extraordinary if we have regard to the resistance of the materials and the manner in which the structure is framed up.

BUILDING AND THE FINANCE BILL.

GROWING OPPOSITION.

The Stoppage of Building Work.

Now that the actual intentions of the Government with regard to the taxation of land are becoming more widely known through the debates in the House of Commons, the building industry is beginning to appreciate what it means; and strong and increasing opposition to the Finance Bill is indicated on all sides. At the end of June, Mr. Howard Colls, of Colls and Sons, the well-known firm of builders, stated to a reporter of "The Daily Telegraph":—"The fear of this Budget has already had an enormous effect in stopping building work of all kinds, and now that it has been put into shape it will still further accelerate and intensify this holding-up of building operations." The state of the building trade was, he stated, worse than he had ever known during the summer months. Work was being stopped and postponed in all directions. If the Government had had a "mandate" so to frame the Budget as to throw men out of employment they could scarcely have done more. It was generally known that in the aggregate the number of men employed in the building trade was far greater than in any single trade throughout the country.

A correspondent in "The Morning Post" of June 28, mentioned the difficulties attendant on mortgaged property. Many are now being called in, and there is little hope of re-mortgaging since the Finance Bill was introduced. Says this correspondent:—"There can be no question but that the building trade will be permanently injured. For many years land and property generally have been depreciating in value, and just as the property market is on the turn it receives this "knock-out" blow. Building work is being stopped or postponed in all directions."

An Architect's Views.

The opinion of a well-known London architect also appears in "The Daily Telegraph" of June 28th. He says that the present panic involves a distressing period of unemployment for thousands of skilled workmen. With all the terrors of this measure facing him, the City man who is about to retire, buy a little estate in the country, build a comfortable house at from £5,000 to £10,000, and become a solid asset to the country, says to himself, 'No, it's not good enough; the responsibilities are too great, and I don't know what sort of taxation I shall be let in for in the future.' "Take, too, the case of a man who seeks to buy a piece of land for his personal occupation. He wants to know that he is buying it with some definite charge, but under this Budget he is in a state of great uncertainty. The old land-tax was redeemed by a good many people, but now things are almost as bad again. I know myself of one instance in which several houses were to have been put up, costing about £12,000. They were dropped through fear of the Budget. Another scheme for building a gentleman's house in the country for £6,000 was given up, and a like fate befel a proposed alteration to a gentleman's private residence, at a cost of £8,500. Sir G. Hayter Chubb announced some time ago that contemplated building operations, to cost some £10,000, were abandoned, and Lord Redesdale, who was interested in some brickworks, stated that two contracts of £10,000 each were dropped, so he was informed by the contractors, in consequence of the Budget. These are but a few actual instances of what is taking place all over the country." Many country builders of the better class had told him that they had never been so slack as they were to-day.

The Surveyors' Protest.

The Surveyors' Institution has drawn up a pamphlet in which they say of the increment value duty, that:

"The imposition of this duty will seriously affect the value of land of every description throughout the country, as investors will naturally prefer to place their capital in securities where they will not run the risk of losing one-fifth of any increased value.

"The Finance Bill has already had a deterrent effect on the letting of building land, and some of the signatories have experienced instances where contracts which were on the eve of completion have been annulled on account of the cumulative taxes proposed.

"The cancelling of these agreements will cause an enormous amount of unemployment in the building and allied trades."

The Queen's Hall Protest Meeting.

A large protest meeting of gentlemen having a practical interest in real estate, was held at the Queen's Hall, London, on July 13, and amongst those present were Mr. John Wood (president Land Agents' Society), Mr. Stenning (president, Surveyors' Institution), Mr. J. M. Beale (past-president, Incorporated Law Society), Mr. Howard Martin (past-president, Surveyors' Institution), Mr. J. Howard Colls (past president of the Institute of Builders and of the London Master Builders' Association), Mr. F. G. Rice (president London Master Builders' Association), Col. Raikes (past-president Land Agents' Society), Mr. Peter Davies (president, Estate Agents' Institute), and many others.

Mr. E. G. Pretyman, M.P., moved: "That, in the opinion of this meeting, the proposals for taxation contained in Clauses 1 to 28 of the Finance Bill, 1909, are destructive of security, financially unsound, arbitrary in administration, unconstitutional in form, and unworkable in practice, and that such proposals will tend to increase unemployment, especially in the agricultural and building industries, and arrest the provision of improved accommodation for the working classes."

Mr. Howard Martin, supporting this resolution, entered an emphatic protest against the suggestion that the tax would reach the rich and let the poor escape. It would fine the rich, but might ruin the poor by checking the building trade (and thus increasing unemployment), by ultimately raising the rents of small dwelling-houses, by depreciating the value of investments in which the thrifty had put their savings, and by causing severe financial difficulty to tradesmen and others owing to the calling in of mortgages.

Mr. J. H. Colls also supported the resolution, and said that if the Government had been given a mandate to produce unemployment they could hardly have gone to work more effectively.

The resolution was carried unanimously, and it was resolved to send copies to the Chancellor of the Exchequer and to each member of both Houses of Parliament.

The Dulwich College Estates.

Mr. Edwin T. Hall, F.R.I.B.A., chairman of the Estate Governors of Dulwich College, writes to "The Daily News" of July 17th, replying to a correspondent of that paper who stated that:—"Right in the middle of South London, with built areas on every side, the Trustees at present think it their duty to hold up 480 acres of land," which is "allowed to waste." Mr. Hall points out that there are "other large areas of uncovered land in Norwood, Streatham, and Penge."

With regard to a suggestion that "the building trades will be benefited," Mr. Hall points out that, according to the last official statistics of the boroughs of Camberwell and Lambeth (in which the uncovered land is situated), there are vacant, within the two boroughs, 4,670 houses, representing a loss to the rates of £65,975 per annum." He argues that the sale must be to some hypothetical buyer who is prepared to sink the following sums:—In land, £200,000; in covering 400 acres with 3,000 houses, costing with fences, etc., at least £400 each, £1,200,000; in road and sewer making, £100,000, and in loss of interest during development, £120,000; a total of £1,620,000.

"Having thus placed 3,000 new houses within an area where there are at present 4,670 to let (continues Mr. Hall) purchasers are to be found. Are the houses to be 'held up' until they can be sold to cover their cost with an addition for profit—i.e., the remuneration of the men who have supervised the laying out and building of the houses, or are they 'there and then' to be sold at whatever price can be obtained for them?"

Mr. Hall goes on to say that the Governors are laying out the estate on a definite "town planning" scheme, that they will not allow overcrowding, and that they insist that the houses shall be built on hygienic principles. "The Governors," he says, "do not contemplate allowing the whole of their 480 acres to be built on, nor even the 400 suggested by your correspondent, but only about 320 acres, the remainder it is proposed to keep open, part as beautiful woodlands, part in oases of eight to twenty acres, interspersed all over the estate, as lungs and playing fields for the inhabitants; thus preserving the amenities of the district and carrying into practice the best features of 'town planning.'"

NATIONAL ASSOCIATION OF MASTER PLASTERERS.

A specially convened meeting of the Executive Council of the National Association of Master Plasterers took place at the Moseley Hotel, Manchester, on July 7th, when an invitation having been also given to the members of the Manchester Master Plasterers' Association to attend, a good representative meeting was the result. The President, Mr. Thos. Lindley, of Barnsley, occupied the chair.

The business of the meeting was to consider, approve, or otherwise, the proposed alterations and additions to the National Agreement between the National Federation of Building Trade Employers, National Association of Master Plasterers, and the National Association of Operative Plasterers. The several variations and additions were explained to the meeting by the president, Mr. J. W. Sugden, past president, of Bradford, and Mr. J. C. Warring, past president, of Sheffield, who were among the representatives of this association upon the Joint Committee, and also by Mr. J. B. Johnson, of Liverpool, a member of this association, and a representative of the Lancashire and Cheshire District of the Federation. A general discussion took place upon the merits of the proposed additions, and satisfaction was generally expressed at the results obtained. It was also pointed out to the delegates that the operatives' representatives had met the employers in a spirit of conciliation, and with the avowed desire to become parties to an agreement that could only tend to the benefit of all parties concerned.

Upon the proposition of Mr. L. Stead, of Bradford, seconded by Mr. J. Gibbons, of Manchester, the secretary was instructed to convey the following resolution to Mr. A. G. White, Secretary of the National Federation: "That this meeting of the Executive Council of the N.A.M.P. instruct their president, Mr. T. Lindley, to attach his signature to the new agreement, as drafted and agreed to by the representatives of the several bodies concerned, on behalf of the members of the N.A.M.P."

A further discussion then took place upon matters generally concerning the trade, but in particular upon the question of sub-contractors' agreements, which it was agreed to leave in abeyance, it being understood that at the next meeting of the N.F.B.T.E. several forms would be submitted, with a view of selecting one that would meet the general requirements of the different branch trades connected with the building trade.—Geo. Soall, Secretary, 100, Lodge Road, West Bromwich.

Federation News.

Northern Counties Federation of Building Trades' Employers.

A quarterly meeting of the Board of Representatives of the Northern Counties' Federation was held at the County Hotel, Westoe, South Shields, on July 9th, Mr. John Davison, president, in the chair, when 44 members were present.

Previous to the meeting, the members were received at the railway station by the officials of the South Shields Association, and were driven by brake along the sea front, thence to the new municipal buildings (Messrs. Neill, contractors), where they were shown over the building by Mr. Yeoman in the unavoidable absence of Mr. Neill.

The minutes of the quarterly meeting held at Middlesbrough on April 15th, which had been published in "The Builders' Journal" were read and were signed as correct.

The Secretary reported that the Darlington Association had still under consideration the question of affiliation with this Federation, and he was awaiting a communication from them.

The Executive Council's report upon the question of the workmen's compensation insurance was received and adopted.

The agreement between this Federation and the Federated Employers' Insurance Association, Ltd., Manchester, was read, and, on the proposition of Mr. W. T. Weir, seconded by Mr. R. Johnson, it was unanimously agreed to, and accordingly signed by the president and the secretary on behalf of the Federation.

The representatives of this Federation upon the Advisory Board established under the agreement were appointed, viz:—J. Proud, president, Teesside Association; R. J. Huntley, president, Sunderland Association; and W. T. Weir, president, Tyne and Blyth district.

The Secretary reported that the question of amendment to the National form of contract would be mentioned at the half-yearly meeting of the National Federation. The amendment put forward by the R.I.B.A., and conditionally agreed to by the London Institute of Master Buildings, with respect to Clause 30, would also receive consideration.

A letter addressed by the different sub-contractors and traders to the Northern Architectural Association asking them to consider the advisability of having direct contracting, was read and laid on the table.

The Secretary reported that he had written to the architect for the alterations and additions to the Auckland Union (who required the return of the bill of quantities before returning the deposit) pointing out that this is not usually asked for, as the bills of quantities contain the figures and prices from which the tenders are made up, and the architect was asked to return the deposits without enforcing the condition attached to the advertisement. It was pointed out that such conditions tended to hamper open competition for work.

The Executive Council reported that the different local associations had protested against the proposal of the Chancellor of the Exchequer to increase the stamp duty from 10s. to 20s. per cent., and had communicated their decisions to the Prime Minister and Chancellor of the Exchequer.

The question of inviting the National Federation to hold their summer meeting in 1911 within the Northern Counties area was discussed, and the secretary read the particulars of the entertainment given to the National Federation by various Federations.

On the proposition of Mr. W. S. Davison, seconded by Mr. R. J. Huntley, it was resolved: "That the question of extending an invitation to the National Federation to hold the summer meeting in 1911 within the Northern Counties area be left in the hands of the Executive Council."

The draft agreement between the National Federation of Master Plasterers and the National Association of Operative Plasterers was considered, and thought to be generally acceptable to this Federation.

The secretary explained the reason for the annual return of workmen, etc., and asked the members to send in at once the form sent to them by their secretaries, so that the result could be forwarded to the National Federation.

On the proposition of Mr. J. W. White, seconded by Mr. J. Proud, the president and the secretary (as substitute for Mr. Wilkinson) were appointed to attend the half-yearly meeting of the National Federation.

On the proposition of Mr. J. W. White, seconded by Mr. R. Johnson, it was resolved to hold the next quarterly meeting of the Federation at Stockton.—W. H. Hope, Secretary, Post Office Chambers, 14, Norfolk Street, Sunderland.

NORWICH AND DISTRICT ASSOCIATION.

Secretary: J. H. Hatch.

The annual outing of the Norwich and District Association took place on Wednesday, July 7th, at Wroxham, on the grounds of "Riversdale," kindly lent by Mr. Charles W. Daws. During the afternoon the members enjoyed a motor-boat trip round Wroxham Broad. The dinner was served in a marquee erected on the grounds, and the chair was taken by Mr. B. E. Searles.

NOTTINGHAM ASSOCIATION.

Secretary: W. J. Barton.

The quarterly meeting of the general committee of the Nottingahm Association was held last week, the president (Mr. W. W. Woodsend) in the chair.

The accounts for the past quarter, as examined y the Finance Committe, were submitted, and the payment of the same was duly authorised.

It was also resolved that a cheque be sent to the Midland Centre as this association's subscription for the current year.

The proposed new agreement between the Federation and the National Association of Master Plumbers and the National Association of Operative Plasterers was considered, and the same recommended for acceptance.

This association has for some time been in correspondence with the Nottingham Architectural Society, as to the payment to specialists for work done on contracts, and it was reported at this meeting that the Architectural Society had now passed a resolution deciding to adhere to clause 28 of the conditions of contract, and that such clause should be strictly observed.

This was considered by the Committee to be a most satisfactory conclusion to the negotiations on this subject.

SOUTH SHIELDS ASSOCIATION.

Secretary: J. G. Robertson.

The monthly meeting of the South Shields branch was held in the Victoria Hall, South Shields, on July 6th. The President (Councillor J. T. Armstrong) presided over a representative gathering, which included Mr. W. H. Hope, secretary of the Northern Counties' Federation, and Mr. W. C. Creasor, of the Teesside district.

It was agreed, after consideration, to accept the amended instructions of the Sunderland and South Shields Water Co., dealing with regulations as to pipes, etc., according to the purport of their letter.

The question of glass merchants giving the same terms to outsiders as to builders was again gone into.—Eventually it was resolved to let it lie over pending an official reply from the glass merchants, which had been promised.

The following letter from the Member of Parliament for the borough, Sir W. S. Robson, K.C., M.P. (Attorney General), was next read re increased stamp duty:—"Dear Mr. Robertson,—I find I have not replied to the resolution from the building trade in reference to the proposed transfer duty. I quite agree that this is a tax that would press inconveniently in several quarters, and I would be glad to see it dispensed with, but I am afraid there is no chance of that. This business of paying the bill for things that everybody wanted is no light matter.—Yours very truly, (signed) W. S. Robson."

The Northern Counties' Federation secretary, Mr. W. H. Hope, next addressed the meeting, giving them various reasons why he thought the branch should place their workmen's compensation with the Federated Employers' Insurance Association, specially dwelling on their cover-all policy. Mr. Creasor, the district representative of the Federated Employers' Insurance Association, supplemented the remarks of Mr. Hope, dwelling particularly on the satisfactory way in which his company had met all claims, and on the special arrangements made for this district to make it practically impossible for trouble to arise on that score, seeing that it had first of all to go before a joint board of three directors of the Federated Insurance Association and three (appointed) members of the Northern Counties' Federation, who failing to agree, had power to call in an umpire. On the proposition of the chairman, a vote of thanks was accorded to Messrs. Hope and Creasor for their attendance, and for the information given. Several questions were asked bearing on the subject. It was, however, resolved to let the matter lie over till the next meeting of the branch.

Councillor J. T. Armstrong was unanimously elected to represent the branch at the half-yearly general meeting at Portsmouth of the National Federation of Building Trades Employers.

Arrangements were made for the entertainment of the representatives of the Northern Counties' Federation on their visit to South Shields for their quarterly meeting to be held at the County Hotel.

The question of having a trip this year was most heartily taken up, and it was agreed to have same to Keswick on Wednesday, August 18th. Messrs. T. Anderson, A. Ross, and J. G. Robertson were appointed a committee to carry out the arrangements.

STOURBRIDGE AND DISTRICT ASSOCIATION.

Secretary—Percival D. Folkes, Chartered Accountant.

On July 13th the members of the Stourbridge and District Master Builders' Association held their annual outing to Holt Fleet, via Worcester. Among the party were Mr. C. Griffiths (president), Mr. T. J. Mason (vice-president), Mr. J. H. Willetts (hon. treasurer), Mr. J. Stokes (president, Worcester M.B.A.), Mr. P. D. Folkes (secretary) and besides members of the Association a number of manufacturers and merchants connected with the trade. After a sail up the river to Holt Fleet, luncheon was served at the Holt Fleet Hotel, where, after the toast of "The King," Mr. Stokes proposed the toast of the "Association," to which Mr. Griffiths responded. Mr. T. J. Mason gave "The Visitors," which was responded to by Mr. T. Freer Ash (Birmingham). On the return journey a short stay was made at Worcester, when the outing was voted one of the most enjoyable the Association has had.

WAKEFIELD AND DISTRICT ASSOCIATION.

Secretary: J. Beaumont.

At a meeting of the Wakefield and District Association, held at the Bull Hotel, Wakefield, on July 8th, Mr. Tom Lee (president), in the chair, the Secretary read the minutes of the meeting of the Yorkshire Executive Council, held at Barnoldswick on June 17th, and Mr. H. Fallas, who had attended this meeting, gave a supplementary report thereon, and specially referred to the excellent report submitted by Mr. A. W. Sinclair (Scarborough) on his recent visit to Germany under the auspices of the Housing Reform Council. On the proposition of Mr. Fallas, seconded by Mr. Elvey, it was decided to recommend the Yorkshire Executive Council to have Mr. Sinclair's report printed in pamphlet form and circulated amongst the members of local associations.

The form of sub-contract which had been prepared and settled by counsel, and submitted to the Association by the Yorkshire Executive Council for consideration, was gone through, and various points in several clauses in the contract, especially those relating to the liability for and insurance against accidents to the workmen of subcontractors, were fully discussed. On the motion of Mr. Elvey, seconded by Mr. Pashley, a special committee, consisting of the president, Alderman Judge, Councillor Spink, Mr. Fallas, Mr. Crook, with the secretary, was appointed to formulate and lay before the Federation Council the views and observations of the Association on the contract, some of the clauses therein not being acceptable to the members.

On the motion of Mr. Elvey, seconded by Mr. Gillott, it was decided to hold the next meeting of the Association on the first Thursday in October.

ARCHITECTURAL & TOPOGRAPHICAL SOCIETY.

The Architectural and Topographical Society have issued an appeal for help in their work, which has been described as one of national interest, namely, that of making complete historical records of the ancient buildings of these islands, from the introduction of civilization to the year 1800. Stress is laid on the following points:—(1) Since the foundation of the society, rather more than twelve months ago, complete accounts of the buildings in seventeen parishes have been published. (2) The value of the work has been endorsed by the fact that many of the leading societies interested in this subject are now subscribing. (3) There are at present some twenty parishes partly completed, in addition to those already dealt with, and several more are definitely promised. The fact that the society can obtain work of this nature entirely gratuitously shows how greatly the need for such records is felt by those who have expert knowledge of the subject. (4) The recent appointment of Royal Commissions to make an inventory of the ancient monuments of England, Scotland, and Wales, shows that the State appreciates the need for such work; and by its terms of reference, the Commission is only intended to make an inventory, and does not in any way cover the ground of this society's labours. (5) The other part of the society's work, which includes the collection of carefully made record drawings, notes, and photographs, etc., is progressing, and a considerable number of such records are now either promised, or are already in our possession. (6) All the work done for the society is purely honorary—therefore its funds are expended entirely on the work, and not in any way upon the workers. (7) A large sum of money is subscribed annually towards the furtherance of similar work in the ancient world of Egypt and Rome, and it would be unworthy of our national traditions should researches into the history of our own country fail for want of funds.

The minimum sum of £500 is required to ensure the effective continuation of the work of the society until such time as the annual subscription list shall be equal to the necessary disbursements; a further contribution would enable the rate of progress to be made more consonant with the amount of the work to be done. Subscriptions and donations should be made payable to the society, and crossed "London and County Bank." All communications should be addressed to the offices of the society at 33, Old Queen Street, Westminster, S.W. Donations will be treated as subscriptions, and donors of half a guinea or more will receive the "Record" for the current year, whilst those of seven guineas and upwards will be entered on the society's list of life members. The appeal is signed by Lord Plymouth, Lord Avebury, Sir Aston Webb, C.B., R.A., and Messrs. Francis Bond, J. A. Gotch, Emslie J. Horniman, M.P., Thos. G. Jackson, R.A., Mervyn Macartney, and Edward S. Prior.

Coming Events

Wednesday, July 14th—Saturday, August 7th.

Town Planning and Housing Exhibition, Hampstead Garden Suburb, London, N.W.

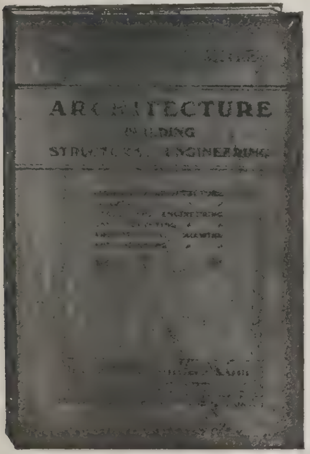
Five Years Ago these Two Men Started Level

—one is still at his bench, toiling hard and long for a slender pittance—the other now occupies a high-grade position in his profession, enjoying high pay, congenial work, influence and power. What is the reason of the present difference in their fortunes? It is not that the successful man has more brains than his "stand-still" colleague of five years ago—**but he does know better how to use them.** In a word, he has **trained** his brains on practical remunerative lines, while the man still at the bench has not.

This instance is just typical of thousands we could cite in which men have devoted a few months to serious home study with the International Correspondence Schools, and, as a direct consequence, have secured a future of success and happiness, while their less ambitious colleagues have condemned themselves to a monotonous continuance of the old round of drudgery.



Free Books on Subjects below.

What about Yourself Five Years from now?

You must be ambitious or you would not have read thus far. Determine then to realise your ambition—to rise out of the rut—by enrolling right away for a course of specialised training with the International Correspondence Schools. Spare time home study only is required. You make the fullest use of your leisure, wasting no time travelling to and from classes. You make every hour you give to study count in your career, for the I.C.S. course arranged for you will have the one and only aim of preparing you for the high grade position to which you aspire.

The evidence of the thousands of students who have benefited by our training during the past 17 years is conclusive on this point. This is how one of them puts it—

Aston, Birmingham.

"There is no doubt that yours is in reality 'the system that raises salaries,' that raises a man who doesn't mind work to the highest eminence in his trade."

(Signed) A. H. Du Rose.

L. & C. HARDTMUTH'S

KOH-I-NOOR PENCIL

is the most economical Pencil made. It lasts six times as long as an ordinary pencil. But it is the velvety smoothness of the lead that is the great charm of the Koh-I-Noor. There is no other pencil that nearly approaches its quality The lead of the Koh-I-Noor is specially prepared by a perfected process which gives it a firmness yet delicacy of touch that cannot be imitated. The Koh-I-Noor is made in seventeen degrees to suit all pencil purposes.

Koh-I-Noor Pencils are **4d.** each, and **3s. 6d.** per dozen, everywhere. Of Stationers, Artists' Colourmen, Photographic Dealers, &c. Booklet free from

L. & C. HARDTMUTH,
12, Golden Lane, London, E.C.

KOH-I-NOOR

TRACING CLOTH

Is a stout and substantial cloth possessing every advantage for the drawing room. Its surface is smooth and clear, free from blotches. Does not tear or break. Is transparent enough for the finest work Erasures may be freely made without causing the ink to run. Is excellent for giving impressions by process

THE GREATEST SATISFACTION IN USING THIS SPECIALITY IS FOUND IN ALL DRAWING OFFICES.

Of Stationers Artists' Colourmen, Photographic Dealers &c

The Ironmongers' Almshouses.

The ceaseless conflict between utilitarianism and sentiment had for its arena recently the council chamber of the L.C.C. The Local Government Committee presented a report in which it was stated that the Ironmongers' Company were seeking permission to sell the site of the almshouses in the Kingsland Road, Shoreditch, to the Peabody Trustees, and to erect almshouses elsewhere. The almshouses, comprising fourteen dwellings and a chapel, were erected on a site of about an acre and three-quarters, in 1716, and have many of the characteristics of good eighteenth-century architecture, and it is contended that London is not so rich in specimens of this period that it can afford to destroy these with a light heart and a heavy hand; whereas, on the other hand, it has, from the aesthetic point of view, quite enough dwellings of the Peabody type. At the public enquiry that has been held, the opposition by the Shoreditch Borough Council, and by societies interested in the preservation of old buildings, seems to have weighed with the Charity Commissioners, who declined to sanction the sale. Thereupon the Ironmongers' Company appealed to the High Court. In the discussion by the L.C.C., Mr. Stuart Sankey declared that these buildings were of no archæological value whatever. Moreover, he said, they were very damp and noisome, and the walls were bulging and old. In their place the Peabody Trustees proposed to erect accommodation for about 1,200 people. The Ironmongers' Company, he added, was one of the richest and most important bodies in London, and had spent a large sum of money in charity. His friends the Ironmongers will probably think that Mr. Sankey doth protest too much. They might even suspect him of irony. If he had seen fit to "combine his information," he might have deduced the very simple proposition that, since dampness, noisomeness, and the bulging of walls, are not beyond the resources of modern skill to remedy, and are not conditions which even the most ardent archæologist would desire to perpetuate; and that since the Worshipful Ironmongers are so plethoric of a nobler metal than that which gives them their honourable name, they could quite conveniently spare a little of it to set their almshouses in order. A utilitarian argument of a different order was advanced by Mr. Barlow, who had less regard for the architectural value of the buildings than for the loss of the open space. Mr. Sturge (Sir John Benn with him) found that the almshouses were "most beautiful specimens of the early Georgian period of architecture, while the gardens were the only open space of any importance in Shoreditch." He added that "the City was removing, one by one, all the ancient landmarks, and that if the German Emperor, or anyone else, should attempt to loot the City, he would find that it had already been rifled by the Goths and Vandals." The picaresque image thus conjured up of the German Emperor, in full panoply of war, weeping over the ruins of the Ironmongers' Shoreditch almshouses, was too much for the councillors. They burst into hysterical laughter, and were apparently so much overcome by their emotions that they forgot to pass any resolution on the subject.

Sanitary Building.

At the concluding sitting of the Tuberculosis Conference at Stockholm, an Englishman—Dr. Hope, Medical Officer of Health for the City and Port of Liverpool—emphasised the wisdom of beginning with the germs. He claimed that the city of Liverpool is a striking example of the success of this thorough policy. Some fifty years ago, Liverpool, in common with most other crowded centres, was a hot-bed of disease. Step by step, as sanitary reforms were introduced, tuberculosis declined. The sanitation of the home, the school, the place of business, the widening of streets, the provision of open spaces, the erection of baths and washhouses, purified and improved water supply, had each and all tended to this result; and if the municipality had neglected such works, and had instead devoted the money spent on them to hospitals and sanatoria, leaving the tuberculosis breeding places untouched, they would have been guilty—although Dr. Hope did not say so—of crass folly, if not criminal neglect of the teachings of modern science. To the enlightened teachings of men of Dr. Hope's profession—Simon, Chadwick, Playfair, and Parkes, Corfield, and the rest, who insisted that disease is preventable and ought to be prevented—these vital reforms may be chiefly attributed; but credit must not be withheld from the authorities who hearkened to their counsels, nor from the architects and sanitarians who have so ably and so enthusiastically translated it into practice. Very much, however, remains to be done, and the architect and builder will be only too glad to assist in doing it. In this splendid campaign against disease, Britain took the lead, and that she still holds it is but dubious matter for self-gratulation. We are proud to have been the pioneers; yet, for the sake of suffering humanity, we should be delighted to find all the other nations well abreast of us in sanitation; but for the self-same reasons, they shall never get ahead of us!

The Federation at Portsmouth.

The visit of the National Federation of Building Trades' employers to Portsmouth, there to hold their half-yearly meetings, was a well-deserved compliment to the local association, which is one of the best organised and most flourishing associations in the kingdom, and this stands out only too prominently from the dead level of lethargy that generally characterises the South of England. It may be said that the compliment was returned with interest—historical and otherwise; for Portsmouth pulsates with the naval power and prowess that have made our country what it is, and may therefore surely claim to be in that respect the most intensely English town in England. "Oh! Portsmouth is a fine town, with ships in the bay!" runs one of many variants on the sailors' old "chanty," and if the "fineness" of the town as a whole is not strictly referable to its buildings, there can be no question that the Town Hall, where the Federation, by courtesy of the Mayor and Corporation, held its meetings, is one of the finest in the Kingdom. It is so dominating and dignified a feature—its tall tower can be well seen, all across the Solent, from the Isle of Wight—as to excuse, if not to justify, the remark of a Federationist that "There is more hall than town." That was probably this builder's way of expressing the fact that the town hall is out of scale with most of the other buildings, most of which are apparently survivals of the worst period of English architecture. But the town has many admirable buildings besides the Town Hall, and as it has more than 200,000 inhabitants, and these seem to be all very decently housed, it follows that the visitor's crude epigram is, after its kind, without foundation in solid fact, as one soon discovers on noting the countless houses that separate the George Hotel (the last house in which Nelson slept) and the unpretentious home in which Dickens was born. And as for the "ships in the bay," those who "want eight" need not "wait," for more than that number can usually be seen in the Solent; but none of them is half so interesting as the grand old "Victory," which, riding serenely in the harbour amidst modern warships and liners, may have suggested to Federationists a very obvious parallel case, in which, for the larger works, old methods of construction are being abandoned, the engineer is superseding the builder, and woodwork is giving place to steel. But the Solent abounds also in smaller craft, which are still built in the old way and of the old material, and their presence seems to carry the parallel, or the parable, a step further. Steel frame building is not required, and is hardly possible, for the great majority of structures! A summer meeting is peculiarly apt to partake of a holiday character; but, nevertheless, the Federation managed to get through a great deal of important business; and it seems to us to be a happy idea to make the summer meeting a movable feast. In this way, business is combined with pleasure; and the happy holiday spirit must be exceedingly useful in its natural tendency to correct acerbity and to promote the harmony and good-fellowship that are not merely enjoyable things in themselves, but are excellent lubricants of business. We heard a Federationist remark that he thought Portsmouth must be "the breeziest, bluffest and sea-saltiest place on earth." Appropriately, the President seems to possess these very characteristics in full measure. At Portsmouth, at any rate, he was breezy and bluff, and showed a full measure of the saving salt of humour—an invaluable asset in a leader of men. Altogether, the Federation is to be warmly congratulated on the entire success of its Portsmouth Conference.

Architectural Copyright. The movement in favour of copyright in architectural design is gathering force everywhere. The Danish Literary and Artistic Association has, at its recent Congress at Copenhagen, reaffirmed the principle, and has demanded for Denmark the assimilation of the rights of architects to those already enjoyed by painters and sculptors, in accordance with the agreement at the diplomatic conference of Berlin, on November 13th, 1908. In most countries the justice of the architect's claim to the protection of his original creation is now not only admitted, but given legislative effect; and it is declared by a French contemporary that in France, where the law on the subject has been actively and definitely in force since 1902, enforcement of the architect's rights has been found to be entirely practicable. The intentions of our own Government with respect to this very important question, will no doubt soon be made public.

Stunned Stonework. Correspondence about the decay of the stonework of some of our most cherished buildings has evoked the opinion of a scientific expert that much of the mischief is probably due to the former ill-considered use of blasting powder in quarrying. It has now become recognised that heavy blasting had the effect of weakening the rock crystals or grains, and quarrymen are now careful not to put upon the market stone that has been stunned, and the wasteful blasting process is being superseded by the use of the wire saw, which cuts the stone from its native bed without injuring its texture. That the crumbling stonework of our venerable buildings may have had its constitution ruined before it was placed in position, and that this condition no longer obtains, is doubtless reassuring to modern builders; but it makes the state of the old work even more hopeless than before. Clearly, if stonework crumbles because its constitution has been shattered while the stone was reposing in its natural bed, superficial treatment must be futile. This is a stunning blow to the anti-restorationists. It is now "up to them" to point out the inestimable advantages of stunned stone, and the insidious wickedness of the wire saw, which, being modern, must therefore be execrable.

THE BARNSLEY SCHOOL COMPETITION.

Through an error on the part of our correspondent it was stated in our issue of last week that the design of Messrs. Clark and Moscrop, of Darlington, was placed third in this competition instead of second, and the drawings given of the second premiated design and attributed to another firm were in reality by them. The accompanying notes on the competition also carry on the same error which we very much regret, and are unable to account for. Our correspondent thinks it must have been due to an error in labelling the designs at the exhibition. Will readers kindly note.

OUR ROYAL ACADEMY BALLOT.

The first ballot of architects to select those of their professional brethren whom they consider worthy of election to the Royal Academy of Arts has now closed, and the cards will be examined this week by the scrutineers, Messrs. A. W. S. Cross, V.P.R.I.B.A., and E. A. Richards, F.R.I.B.A. The percentage of those voting was higher than expected. About 40 spoiled cards were received, the majority being returned cards, the addressees having removed. A few of the others exhibited choice specimens of the office boy's humour, while some conveyed the disapproval of the ballot by the writers or their decision not to vote. One gentleman waxed wroth with us on our attempt to dictate to the Royal Academy, as if that institution were one of the elemental forces of nature instead of an association of painters and sculptors, several of whom have expressed to us their difficulties in voting for architects owing to their ignorance of the standing and work of the candidates. For their guidance our ballot was instituted, and we have, so far, every reason to be gratified by its success. In all, over 100 architects have received votes; and the object of this first ballot is to determine the first twenty of them who will be eligible for the second ballot.

NATIONAL REGISTRATION OF PLUMBERS

Examinations for master plumbers and operative plumbers in technical knowledge and workmanship are held in London and the chief centres of the United Kingdom for the purpose of rendering plumbers who pass the examinations eligible for certificates and registration. Only plumbers holding such certificates and registered are entitled to describe themselves as "registered plumbers." Particulars of the examinations and lists of registered plumbers may be obtained from the General Council for the National Registration of Plumbers (acting with the Plumbers' Company), 54, Parliament Street, Westminster.

HAMPSTEAD TOWN PLANNING EXHIBITION.

A Town Planning and Housing Exhibition at the Hampstead Garden Suburb, London, N.W., was opened on July 14th, by the Right Hon. Alfred Lyttelton, K.C., M.P., and will close on August 7th. Plans, photographs, and models illustrating town planning and city development are on view; cottages and houses, furnished and unfurnished, are thrown open for inspection; specimens of school gardens, children's playgrounds, and vacant land cultivation are to be seen; and on Wednesdays and Saturdays there are lectures by authorities on town planning and city development.

At the opening lecture, by Prof. Beresford Pite, Mr. Ernest George, President of the Royal Institute of British Architects, who was in the chair, remarking on the presence of members of the German Garden City Association, said that we in England have a great deal to learn from what is being done in the Fatherland.

Prof. Pite gave an admirably impartial summary of the advantages and disadvantages of town planning, and of the difficulties of the problem. The ancient city had been the sport of chance; the modern city would be the concrete expression of intention. A wise and educated knowledge of architecture, and familiarity with local conditions and character, are essential to success in town planning; but there is great need to educate on more enlightened lines the race that is busy building without adequate guidance.

Mr. Raymond Unwin also pleaded for a greater breadth of outlook on the part of architects, each of whom must now turn his eyes from the self-complacent prominence of his own particular building, and have a greater regard for its subordination to an ordered plan and a harmonious assembly.

Mr. S. D. Adshead urged the importance of educating the architect in the principles of town planning.

Mr. Lyttelton presented an address of welcome to the representatives of the German Garden City Association, stating that the founders of the Hampstead Garden Suburb Trust owed the results of much of their effort in this country to the inspiration of German example. The estate would provide houses for 10,000 people, with an average of eight houses to the acre, one family only being domiciled as a rule in each house. The concluding words of the address were as follows—"Emulation among nations is inevitable, and many believe it to be a spring of success. Let us hope that our peoples may strive in fields such as those in which we welcome you to-day, and that by their effort home life in Germany as in this country may be enriched and adorned, and friendship, based on knowledge between classes and nations, may be fostered and advanced."

Mr. Lyttelton said that the tendency in this country was to gravitate towards the towns. The object of the movement in which they were interested was, as far as possible, to turn that tendency to the best account, and to counteract whatever was mischievous in it. Something like a quarter of a million sterling had been expended on the estate.

At the luncheon which followed, Mrs. Barnett, responding to the toast of "The Town-Planning and Housing Movement," proposed by Sir J. Dickson-Poynder, M.P., said that, while character made environment, it was equally true that environment made character, and she believed in fostering that old-fashioned virtue, house pride, which was founded on thrift, forethought, and the power of taking pains. Such a suburb as the one where they had met enabled a woman to have a house in which she could take a pride, and a man to have a garden in which his leisure would be well employed.

After Mrs. W. H. Lever had also spoken, Mr. Vivian and Mr. G. R. Benson proposed the health of the guests, for whom Herren Bernhard Kampffmeyer and Dr. Rehorst replied. The latter gentlemen expressed the hope that the interchange of ideas on social subjects of this character would promote a good understanding between the two countries.

Examination Results.

School of Architecture, University of Liverpool.

At the degree ceremony at the Liverpool University, on July 10th, in St. George's Hall, Lord Derby, the Chancellor of the University, announced the following awards: — Travelling Scholarships: Holt Travelling Scholarship (£50), L. B. Budden; Sydney Jones Travelling Scholarship (£25), H. A. Dod; University Scholarship in Architecture (£50), L. B. Budden. Degrees: B.A., with 1st class honours in architecture, L. B. Budden (thesis, accompanied by measured drawings, "The Greek Revival in England"); H. A. Dod (thesis, accompanied by measured drawings, "The work of Wren and Gibbs at Cambridge"). Pass Degree: S. H. Colton (thesis, with measured drawings, "The work of Cockerell and his Associates"). First class certificate: T. E. Forster. The above are exempted from their Intermediate Examination, R.I.B.A.

The Carpenters' Company.

At the recent examinations in carpentry and joinery held in London and Manchester, the following candidates, in alphabetical order, passed successfully:—Bronze Medals: W. G. Fernie, James A. Haigh, P. Kilburn, Stanley Massey, B. Moore, Chas. H. Overend, E. Whitaker. First Class Certificates: M. C. Blamey, C. Burle, G. J. Chappell, F. Gardiner, F. Garner, R. Garnett, Arthur George, J. H. Higson, H. J. Kent, H. E. Kinns, A. Maclean, M. Henry Midghall, J. Roebuck, O. J. Sharp, A. H. Smith, R. Sykes, E. E. Syms, C. Williams. Second Class Certificates: A. C. Andrews, R. J. Back, G. B. Bardsley, J. W. Barthram, Henry Binks, A. E. Bonfield, J. B. Bonthrone, G. L. Brown, W. R. T. Cook, A. Cropper, D. I. Davies, J. H. Dixon, W. J. Dorey, J. M. Dovey, S. Hill, J. M. Jarvis, J. W. Jones, C. H. Kendall, H. Last, J. R. Saunders, B. T. Scott, Wm. Todd, G. Whiteside, A. J. Wiseman, C. E. Worsfold.

COKE BREEZE IN CONCRETE.

With reference to the paper on this subject read by Mr. D. B. Butler to the Society of Architects, and summarised in our issues of April 28th and July 9th, a correspondent of the "Times" makes a statement to which Mr. Butler replies as follows:—"Referring to my recent experiments he says:—'The expansion as measured on the small bars which Mr.

(*See also last week's issue.*)

Butler employed cannot be considered as satisfactory, for the bars were not large enough to ascertain correctly the actual amount of expansion.' "If," writes Mr. Butler, "the correspondent will kindly refer to the paper in question, which was published in full in more than one technical journal, he will find that the method of measurement adopted—i.e., prisms 100mm. long and 22 by 22 mm. in cross section, measured in the well-known Bauschinger micrometer calliper apparatus, enabled a variation in length of 1/200mm., or .005 per cent., to be detected with certainty. I do not know what greater accuracy the correspondent would require, but I venture to doubt if the larger bars he suggests would be measured with equal accuracy by ordinary methods of measurement.

"I am also somewhat at a loss to understand the correspondent's statement that my researches showed the chemical action of the breeze upon the reinforcing bars to be more serious than the expansion it caused. As a matter of fact, my experiments were, in this instance, exclusively limited to the expansion question, and only passing reference was made to the rusting effect of the breeze concrete upon the iron moulds in which the Bauschinger bars or test pieces were moulded.

"As I stated towards the end of my paper, although these experiments included the preparation of some 300 test pieces, involving some 5,000 measurements, they only touch the fringe of a wide field of research in which there is a vast amount of work yet to be done; but what they do show very clearly is that, apart from the important question of corrosion of the steel reinforcement, there is not much danger to be apprehended as regards subsequent expansion from the use of pure breeze—i.e., fine coke—but that the danger really lies in the use of ashes and furnace refuse of all kinds, which are improperly described and supplied as breeze. In passing through the London streets one has only to notice the absolute rubbish being delivered alongside buildings in the course of construction for breeze concrete purposes to appreciate the force of the foregoing remark."

His Majesty's Office of Works has placed the order for the whole of the large ornamental sashes and bronze casements in the new King Edward Building, G.P.O., E.C., with Messrs. George Wragge, Ltd., 209, Shaftesbury Avenue, W.C., and Manchester, who are now carrying out the work under the direction of the architect, Sir Henry Tanner.

Obituary.

Mr. J. A. Campbell, F.R.I.B.A.

We regret to announce the death of Mr. John Archibald Campbell, F.R.I.B.A., of St. Vincent Street, Glasgow, which occurred suddenly on the 19th inst., while on a visit to his sister at Edinburgh. Mr. Campbell was born in Glasgow in the year 1859, and was a son of the late Mr. Archibald Campbell, merchant, Glasgow, grandson of the late Mr. Wm. Campbell, of Tullichewan and a second cousin of the late Sir H. Campbell-Bannerman and the late Mr. Jas. A. Campbell, of Stracathro. He was educated at the Gordon College, Aberdeen, and Glasgow University. After serving his apprenticeship with the late Mr. John Burnet, architect, he studied in Paris from 1880 to 1883, and won the Tite prize in 1885. He was a partner in the firm of John Burnet, Son, and Campbell from 1896 to 1897, but started business on his own account in the year 1897, and recently assumed Mr. A. D. Hislop as a partner. Mr. Campbell was a prominent member of the Glasgow Institute of Architects, and a Fellow of the Royal Institute of Architects. He was also a member of the Trades House and a Burgess of the City of Glasgow; a member of the Western Club, and served on the committee; a member of the Corporation of Masons, an active member of the Glasgow Art Club, having held the position of hon. secretary. He was at one time interested in golf, and was a member at the time of his death of the Prestwick and Ranfurly Golf Clubs. Among the most important buildings erected from his designs were the West George Street Property Co.'s building at the corner of West George and Hope Streets; Dundas House, Buchanan Street; the Edinburgh Life Assurance Buildings, St. Vincent Street; the Queen Victoria School and Memorial Chapel, Dunblane; and the Northern Assurance Buildings, at present in course of erection in St. Vincent Street. Mr. Campbell, who was a bachelor, took no active interest in politics.

* * *

Mr. John Wornham Penfold, whose death is announced, was an old and highly respected member of the Surveyors' Institution, to which body he acted as hon. secretary for many years. As surveyor to the Goldsmiths' Company he took an active part in rebuilding the quarter of the City about Jewin Street—especially connected with the Manchester trade—after the great fire which occurred there some 20 years ago; and he represented the Crown in the negotiations incident to many of the large purchases which have been necessary in recent years for the extension of Government offices. In the expansion of Haslemere, Mr. Penfold's services as an architect were of great value to the neighbourhood. He was peculiarly happy in enlarging and adapting the cottage or small farmhouse for the purposes of summer or week-end residence; and it is largely due to his taste and ingenuity that Haslemere has been saved from the rawness and garishness too often characteristic of a growing place. Mr. Penfold will also be commemorated in Haslemere by a most useful cottage hospital, which some years ago he generously built and endowed from his private means.

* * *

The death has occurred of Mr. John Gallimore, of Newcastle, who was the builder of Manchester Post Office, as well as post offices in other parts of the country.

* * *

Mr. John Haggas, of Devonshire Street, Keighley, and head of the firm of Messrs. John Haggas and Sons, architects, Keighley, died with tragic suddenness at Morecambe, at the age of sixty-eight years. Mr. Haggas, who had lately suffered from heart affection, travelled by the 5.19 train from Keighley to Morecambe on Friday afternoon. Shortly after arrival he was taken ill, death ensuing about one o'clock the following morning. The deceased gentleman had been in business for nearly forty years, and had designed many local buildings, including the Keighley Town Hall. He never took any active part in local public or political affairs, being of a very quiet and retiring disposition. He was a regular attender at the Devonshire Street Congregational Church. Mr. Haggas leaves four sons and two daughters.

* * *

Mr. Robert Cole, builder, who has died at Stamford Hill at the age of fifty-seven, had had much to do with building developments at Stamford Hill and Clapton.

Notes and News.

In reply to a question by Mr. Gibbs in the House of Commons on the 20th inst., Mr. Harcourt stated that the removal of the equestrian statue of King Charles I. when the new thoroughfare was opened up between Charing Cross and the Mall, was reserved for future consideration. He (Mr. Harcourt) was waiting for the London County Council proposals as to developments on the Trafalgar Square side of the building.

* * *

The Representatives of the Ministries of Marine, Finance, Public Works, and Fine Arts, who have been considering ways and means of preserving the insular character of Mont-Saint-Michel, have submitted their report to their respective departmnts. The committee recommends that no further concessions for the reclamation of land from the sea should be granted, and that round the mount should be drawn a zone extending to a distance of at least 1,500 metres towards the east, and in the west to a distance which would be fixed by agreement with the Compagnio des Polders. Steps are to be taken to stop the progress of the work of reclamation. With regard to the dyke which joins the mount to the mainlaid, two alternative proposals are made—either to preserve the dyke with the exception of a section some 200 metres long, starting from the mount which would be spanned by a bridge, or to bridge the whole channel with a bridge 1,500 metres long. It is believed that a judicious modification of the Roche Torin Dyke would promote a free flow of water which would help to clear the bed of the bay. These proposals are to be submitted to the Bridges and Roads Department for examination with a view to ascertaining their cost.

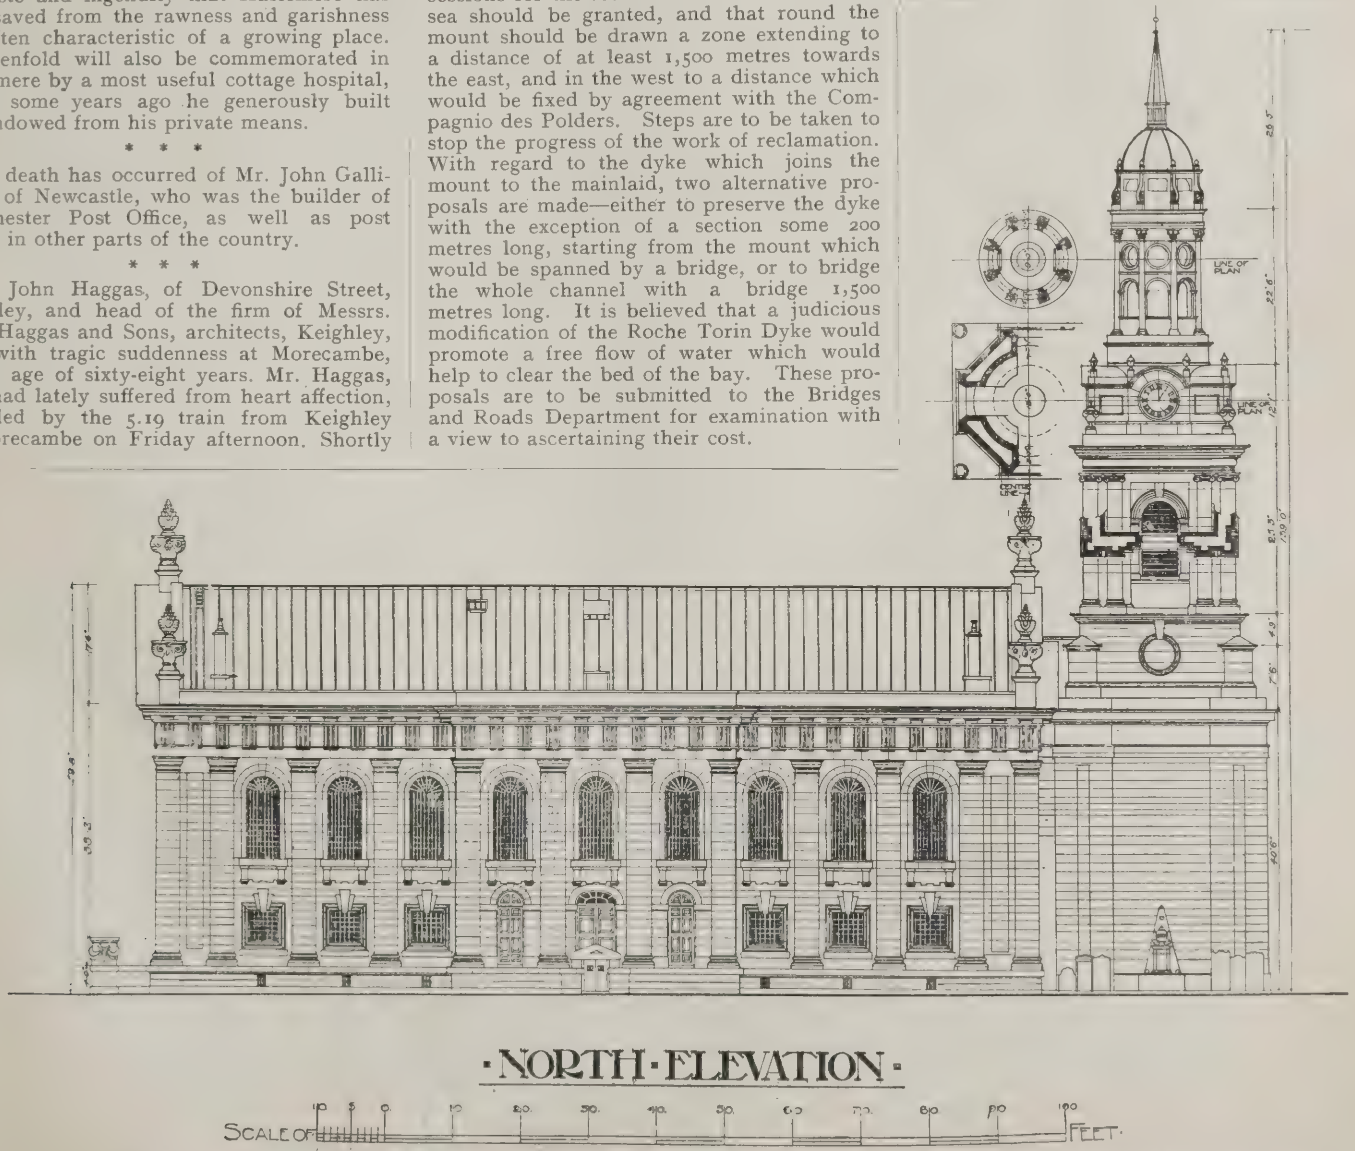
The strictness of the building laws in Paris has been exemplified in the case of a fine prospect which has been preserved from partial disfigurement in the Place de l'Etoile. Here a new hotel has been erected, and the surveyors have discovered that the building is about 32ins. higher than the law allows. An order has been issued to the landlord to have the building reduced to the legal height, but as he refused to obey it the municipality is about to carry out the work itself at a cost of £2,800. This sum will be recovered afterwards from the landlord.

* * *

To cope with their increasing London business, Messrs. Henry Johnson and Sons, plasterers, slaters, and tilers, of Liverpool, London, and Johannesburg, have taken more commodious premises at 69, Victoria Street, Westminster, S.W. Their telephone number is accordingly altered to 5,419, Westminster.

* * *

A society has been formed under the title of "The Technical Essay Society," for the purpose of developing and stimulating interest in the various branches of the building trade by the writing of essays. Subjects will be chosen from time to time, and competitions held, in which the society's medals will be awarded. Wherever possible, the winning essay will be published in a building trades journal. A committee is being formed to appoint judges, select subjects, and carry on the business of the society. Intending members should forward name and address to the hon. secretary, Mr. S. J. Adcock, Weeting, Brandon, Norfolk. The subscription is nominal, all services being honorary.



THE CHURCH OF ST. ALFEGE, GREENWICH. MEASURED AND DRAWN BY FRANK A. COLLARD. *(See also last week's issue.)*

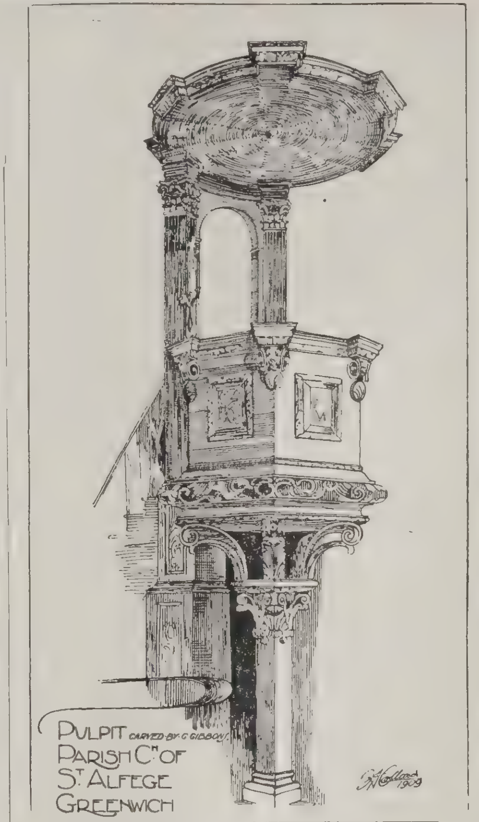
The Council of the Association of Teachers in Technical Institutions, acting on behalf of members of the association who are teachers of artistic trades, and crafts (such as bookbinding, cabinet-making, wood-carving, upholstering, goldsmiths, silversmiths, jewellers and metal workers) desire to draw attention to a series of resolutions embodying reforms which they consider urgently needed in the interests of English craftsmanship. These recommendations are the outcome of contributory papers, discussions and enquiries, extending over a long period among members of the London Arts and Crafts section, who besides being technical teachers, also include employers, foremen, journeymen, trade unionists, and day trade school teachers. In conducting these enquiries, the following main divisions have engaged attention. 1, The standard of work; 2, the relative amount of hand and machine work in each craft; 3, the conditions of apprenticeship and the existing means of training apprentices; 4, the work of existing evening trade classes; 5, the need or otherwise for day trade schools.

* * *

At the monthly meeting of the Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels held at the Society's House, 7, Dean's Yard, Westminster Abbey, the Rev. Canon C. E. Norman in the chair, grants of money were made in aid of building new churches at Lower Mitton, St. Michael, near Stourport, £75; Merton, St. John the Divine, Surrey, £125, for the first portion; and Purlwell, St. Andrew, near Batley, Yorks, £125; towards rebuilding the church at Haslington, St. Matthew, near Crewe, £50; and towards enlarging or otherwise improving the accommodation in the churches at Boyne Hill, All Saints, near Maidenhead, £75; Cann, St. Rumbold, Dorset, £15; Fincham, St. Martin, Norfolk, £20; Hedworth, St. Nicholas, Durham, £35; Ipswich, St. Bartholomew, £20; Llanddewi, St. David, Denbigh, £10; Sefton, St. Helen, near Liverpool, £40; Skenfrith, St. Bridget, near Monmouth, £25; Trent Vale, St. John the Evangelist, Staffs, £50; Warmley, St. Barnabas, near Bristol, £20; and Whatcote, St. Peter, Warwickshire, £15. Grants were also made from the special mission buildings fund towards building mission churches at Caergeiliog, near Holyhead, £15; Nedging Tye, Suffolk, £5; Scackleton, near York, £20; and Washford, near Taunton, £30. The following grants were paid for works completed:—Hill, St. James, near Sutton Coldfield, £75; Shuttington, St. Matthew, near Tamworth, £25; Eastney, St. Margaret, Hants, £200, on account of a grant of £1,000; Sunnyside, St. Michael, near Berkhamsted, £120; West Kirby, St. Andrew, Cheshire, £155; Epsom, St. Barnabas, Surrey, £120; Southover, Wells, Somerset, £25; Charterhouse-on-Mendip, Somerset, £20; Ebbw Vale, Monmouth, £10; and Methwold, Norfolk, £15. In addition to this the sum of £206 was paid towards the repairs of eleven churches from trust funds held by the society. Nine thousand one hundred and sixty places, more than half the parishes in England and Wales, have been aided by the Society with grants from the general fund amounting to £1,062,765, and 973 grants have been made from the mission buildings fund amounting to £26,229.

* * *

The West Riding Finance Committee have for some time had under consideration the work of the architect's department, and have arrived at the conclusion that the work under the Education Acts is sufficient to absorb the entire time and attention of a competent architect. They therefore recommend that the West Riding architect's department be reorganised and divided into two sections, each to be under a competent architect, one to take charge of the work of the Education Committee, the other to take the rest of the work; that the salary of the West Riding architect be reduced from £1,500 to £1,000 per annum as from 1st January, 1910, provided he agrees that he will not make any claim for compensation by reason of such reduction; and that an architect be appointed to carry out the work of the Education Committee at a salary not exceeding £500 a year.



* * *

The Building Act Committee of the London County Council, in accordance with the terms of the reference empowering them to meet as often as may be necessary when the Council is in recess, have decided to hold the summer recess meeting on Tuesday, August 31st. They have also decided that no matters involving important questions of policy or principle shall be dealt with at that meeting.

* * *

The Bill for the Registration of Architects in the Transvaal, promoted by the Institute of Architects in the Transvaal, and supported by the Society of Architects of London, has passed both Houses of the Legislature.

Societies and Institutions.

Northern Architectural Association.

The members of the above association held their annual excursion on Wednesday, July 14th, when a visit was paid to Selby and neighbourhood. Among those present were Mr. G. T. Brown, president, Mr. H. C. Charlewood, Mr. C. S. Errington, Mr. J. Oswald, Mr. J. Bruce, Mr. W. Milburn, Mr. J. Hall, Mr. F. E. Dotchin, and Mr. J. B. Cubey. The party proceeded to Selby Abbey, where they were welcomed by the vicar, the Rev. M. Parkin, who conducted them over the building. Mr. Searle (clerk of works) explained in detail the progress made in the restoration necessitated by the lamentable fire of 1906. Driving to Hemingbrough, the party was met by the Rev. W. P. Wright, who very kindly gave a most interesting description of the church, which is one of the most interesting in Yorkshire. Much interest was manifested in both the abbey and church, and on returning to Selby dinner was served at the Londesborough Hotel.

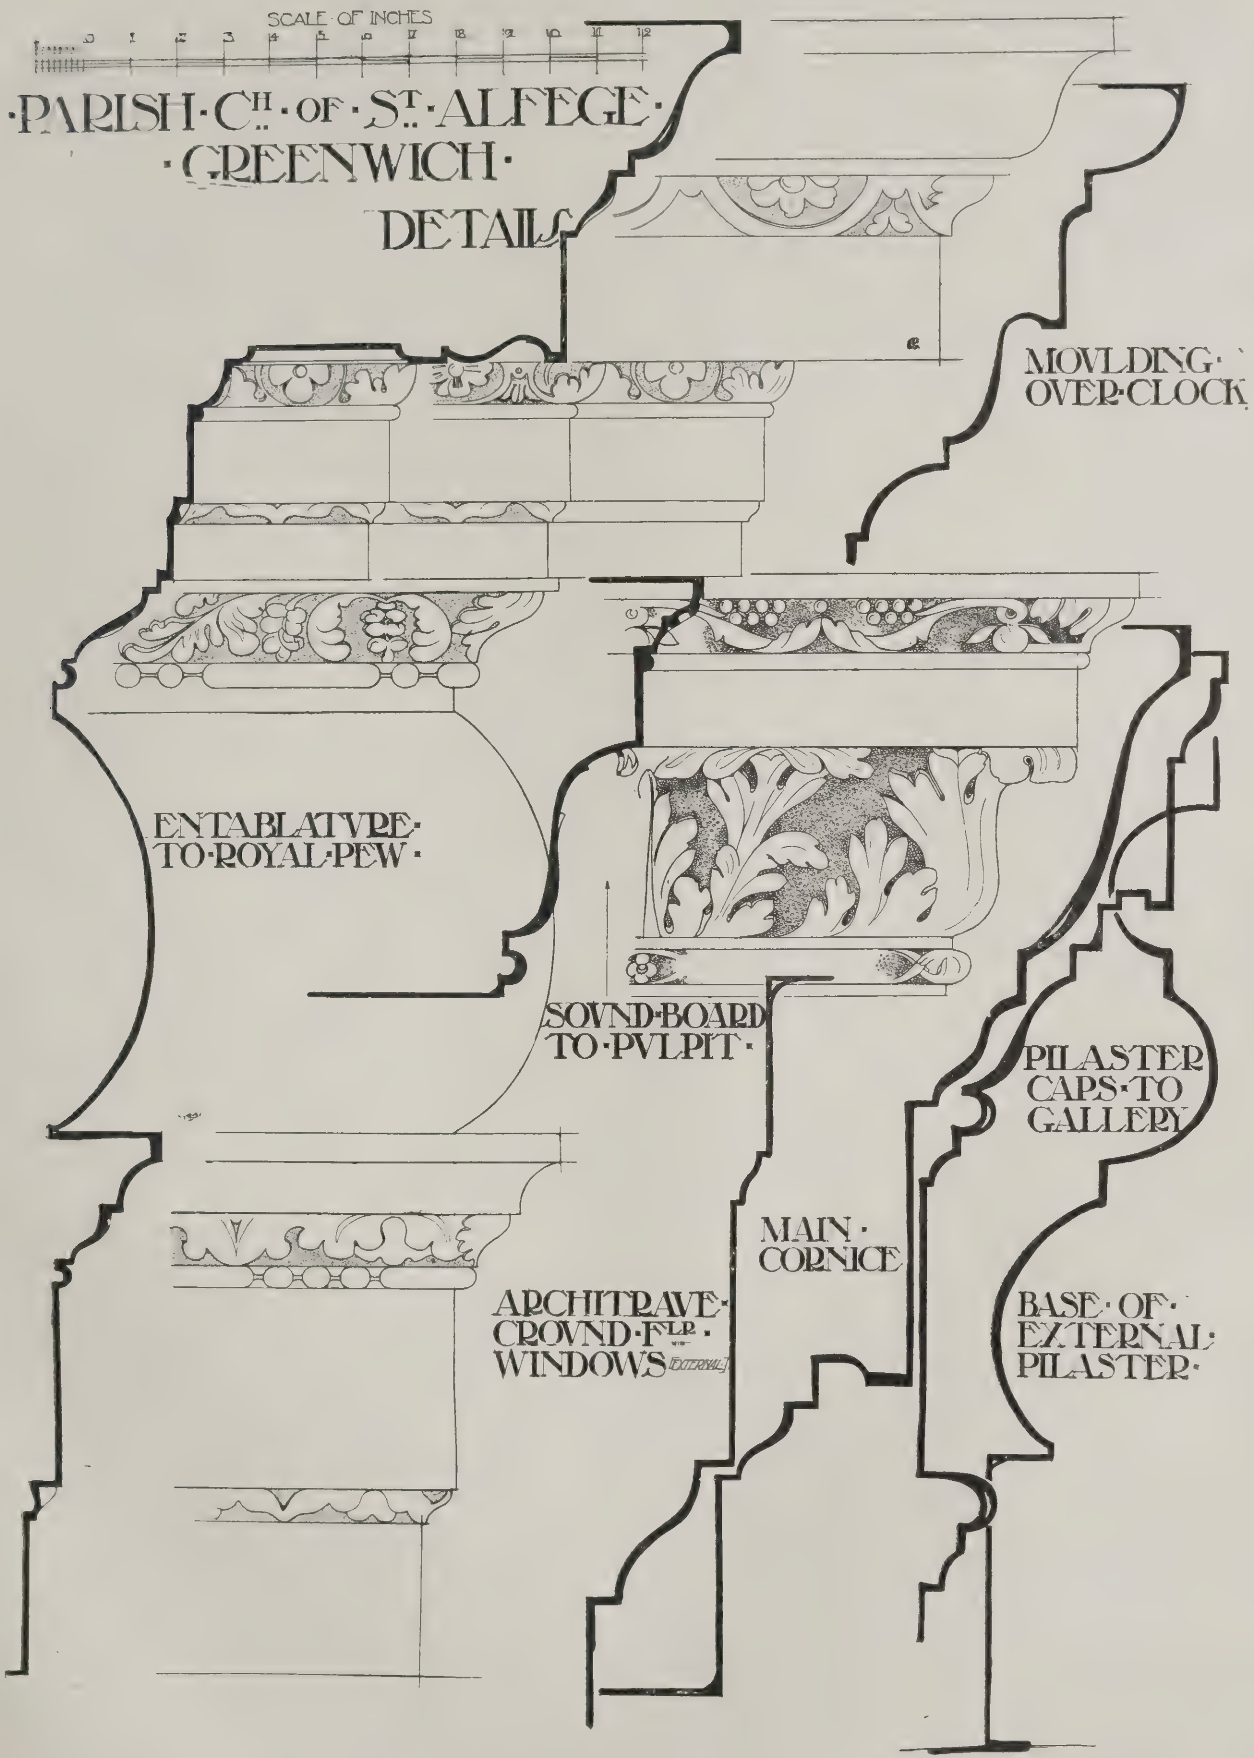
Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
July 30	GRIMSBY TOWN HALL EXTENSION. Estimated cost £26,000. Conditions of competition sent to any applicant on receipt of a stamped addressed foolscap envelope. Full particulars, schedule of requirements, plans of existing buildings, etc., on receipt of deposit £2 (cheques to be made payable to Frank Stephenson, Borough Treasurer), which deposit will be returned to those who send in designs, or if the whole of the particulars are sent back within ten days from the date of their receipt by the applicant. Premiums of £250, £150 and £100. An Architect of eminence will advise in conjunction with the Borough Engineer. Applications to be made to the latter, H. G. Whyatt, Assoc.M.Inst.C.E., Town Hall, Grimsby.
July 31	LAYING OUT ESTATE AT EASTWOOD, RENFREWSHIRE. The patrons of the Royal Incorporation of Hutcheson's Hospital, Glasgow, invite competitive designs for laying out for feuing and building their lands of Thornliebank, containing about 195 acres. Particulars, conditions, and skeleton plans from the Chamberlains to the Hospital, Hill and Hoggan, 194, Ingram Street, Glasgow, to whom designs are to be sent. Premiums, £100, £75, £50, and £25 for the first four designs, *which will become the property of the patrons, who will not be bound further to employ the authors.* Deposit, £3 3s.
Aug. 30	FOREST HALL, Elementary school for 250 scholars. County of Northumberland Education Committee invite designs from architects practising in the County and in the City and County of Newcastle-on-Tyne. Particulars, conditions and plan of site from C. Williams, Secretary to the Education Committee, The Moot-hall, Newcastle-on-Tyne.
Aug. 31	HUDDERSFIELD NEW CHURCH. Plans are invited for a church to seat 400, to cost about £2,000, not to exceed £2,500, with all fittings, furnishings, lighting and heating apparatus. Plans to be forwarded to the Rev. D. Macræ Tod, B.D., St. James' Manse, Huddersfield, by Aug. 31.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.
Sept. 20	HULL TRAINING COLLEGE for teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from Mr. T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.

The first motor sub-station of the London Fire Brigade, giving accommodation for two motor fire-escapes, was opened on the 20th inst.



MEASURED AND DRAWN BY FRANK A. COLLARD.

(See also last week's issue).

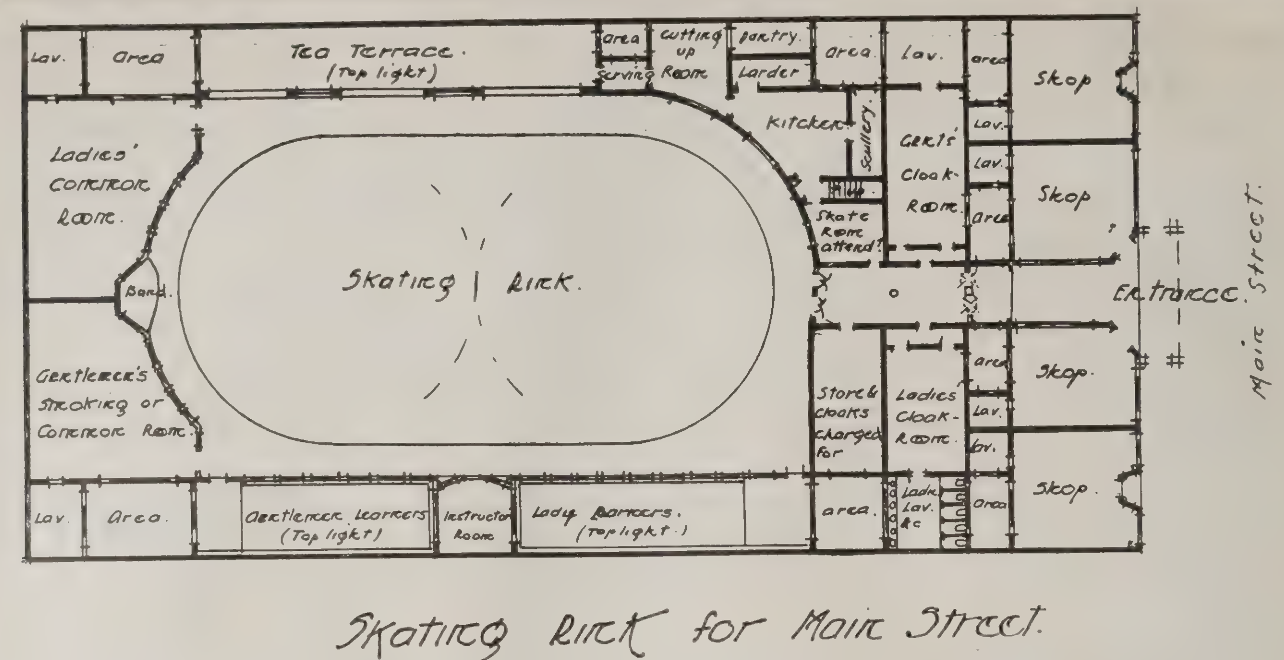


FIG. 1.—PLAN FOR A ROLLER SKATING RINK. E. C. MORGAN WILLMOTT, A.R.I.B.A.

THE DESIGN AND PLANNING OF ROLLER SKATING RINKS.

By E. C. Morgan Willmott, A.R.I.B.A.

The present popularity of roller skating has given rise to a demand for places possessing the accommodation and conveniences necessary to this revived recreation, and some notes relative to their design and planning have been deemed expedient.

Within the brief scope of this article we have three classes of roller skating rinks to consider: first, there are those rinks which can be adapted to the needful conditions by certain alterations and additions to existing premises; secondly, there is the new rink built more or less as a temporary building; and, thirdly, there is the rink which will be contained within a permanent building structure.

It is to be doubted whether the investor can be tempted to put money into a building of a permanent character, for he not unreasonably fears that the present boom may be only a passing craze. Hence the majority of rinks now being laid down are housed within buildings of a very temporary character.

Before, however, considering the fuller details of construction and materials, it will be as well to sum up the various points relating to site, planning, and accommodation, and it is to be remembered that these notes will fully apply to rinks adapted from existing premises. Preferably, of course, an open site is desirable, although, in our large provincial towns, this will be more or less impossible to obtain, as conditions render it imperative for financial success that the rink should be as conveniently and centrally situated as possible. Again, certain forms of top or clerestory lighting are desirable, so an enclosed site is not disadvantageous in this respect.

The accommodation will, of course, depend upon the class of person who will use the rink; but, obviously enough, the small or select rink will be designed with greater regard to privacy and more in the nature of club premises.

For the large public rinks, however, there will be the rink proper, entrance vestibules, skate rooms, offices, manager or secretary's room, cloakrooms for each sex, with lavatories adjoining, band stand, tea terraces or refreshment rooms, and perhaps also a gentlemen's smoke room and ladies' general or common room, pay office, instructor's room, kitchen, scullery, service room and larders. This would be approximately the full extent of the accommodation required, but there would also be certain rooms contingent to others already mentioned.

Fig. 1 represents an attempt which the author has made to realise the best form of premises for a roller skating rink, and a building which practically comprises this plan will at once be erected in South Wales. In it an endeavour has been made to realise the good points of many differing plans. This plan provides for a skating rink with a frontage in a main street, with shops at each side of the entrance. Over the shops will be showrooms and offices suitably arranged in suites.

A wide central entrance is provided, which gives direct access on to the rink proper, and it is in regard to the arrangement of this that the chief word must be written. It will be seen that the rink is so arranged as to comprise proportionally two circles touching each other tangentially, this being, in the author's opinion, the ideal proportion. Such a rink provides a sufficiency of curve to allow of the maximum of pleasure to be obtained from speedy skating, without in any way so confining the curve as to produce giddiness; at the same time, the absence of any great length of straight discourages racing and recklessness. There will be an open barricade of a substantial character, and about 3 ft. 6 in. to 4 ft. high, and on the other side will be a walking space and place for skaters to take a chair and put on their skates. It is important that this walking space should be at least 10 ft. wide. Sometimes, besides this, small galleries are also provided, as in the plan of the New American rink at Cardiff. These galleries can be used both for skaters and spectators. In respect to the latter, one cannot help thinking that sufficient provision should be made for them in every rink, as certain people are always glad to look on when they cannot actually participate in such a sport as roller skating. Were rinks planned in a manner calculated to attract the spectator an added source of profit might form an additional temptation to prospective shareholders. In the rink illustrated in Fig. 1 we see a ladies' common room and a gentlemen's smoke-room, also a spacious tea terrace, where spectators and skaters can obtain light refreshments. Kitchen, servery, cutting-up room, scullery, larders, etc., are conveniently provided for this purpose. Gentlemen's and ladies' rooms are also provided with lavatories lighted by suitably disposed areas. The best place for the band in such a plan as is considered in Fig. 1 is undoubtedly in the position shown, viz., contiguous to the common rooms, for if it is placed in any other position the noise created by the skating almost invariably drowns the music. In this case, however, it would at least be heard in the common rooms.

Varying authorities have considerably varying opinions as to the merits or demerits of different kinds of floors. Originally a fine Portland cement finish to a 6 in. concrete floor was considered to be excellent, but the danger occasioned by a heavy fall has mitigated against its successful adoption. Again, it is cold and comfortless, and does consider-

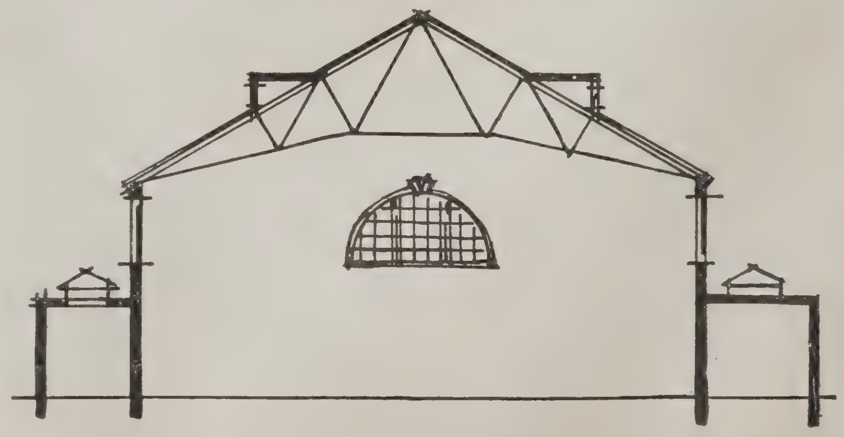

FIG. 2.—SECTION SHOWING A FORM OF ROOF CONSTRUCTION SUITABLE FOR ROLLER SKATING RINKS.

able damage to the skates. Cement or asphalte is never perfectly level, and the latter works greasy, and is therefore slippery in damp weather. It is also heavy to skate upon during the warm weather, as it becomes less hard. Marble slabs properly laid and grouted in cement have been used with a great degree of success; but as this material is expensive, it could only be used in private rinks of a small size. A rink with the floor prepared in this manner would have the same disadvantage as concrete for those skaters not sufficiently skilful to avoid falling.

The general consensus of expert opinion prefers a maple floor laid in narrow widths. Mr. T. Maxwell Witham gives an interesting description of the manner in which he thinks a floor of this kind should be laid with red pine strips 1 in. to 1¾ in. wide. A log would be sawn into these strips, each strip to be cut so as to ensure that the edge of the grain shall be uppermost; in other words, that no strip has the grain of the wood parallel or flat to the surface. The floor is made by being put together in sections, and each section consists of eight or ten strips, say, 10 ft. long, and at the back of each section battens are laid across diagonally, about 4 ins. apart, and these are screwed or nailed with round nails to the strips. The battens being laid diagonally across the strips, the sections will open and shut like a parallel ruler. The ends of the battens project so as to enable the sections to interlock, and the butt ends of each section, being properly squared, are grooved, and when one butt end is placed flush up against another an iron tongue is driven into the groove, and the butt ends are thus prevented from springing. The floor is laid on an ordinary floor, and the sections are laid down beginning from the outsides of the rink and meeting in the centre. These two middle sections are not interlocked, but a strip of pine wood is placed at the ends of the projecting battens and screwed down to the floor underneath, the screws in this batten being the only ones necessary in the whole floor. If in very hot weather the floor opens at all, a wedge driven in between the wall and the floor tightens it all up. The wear to be got out of a floor made and put down in this way is astonishing. The floor of the Crystal Palace skating rink was put down in this manner in 1876.

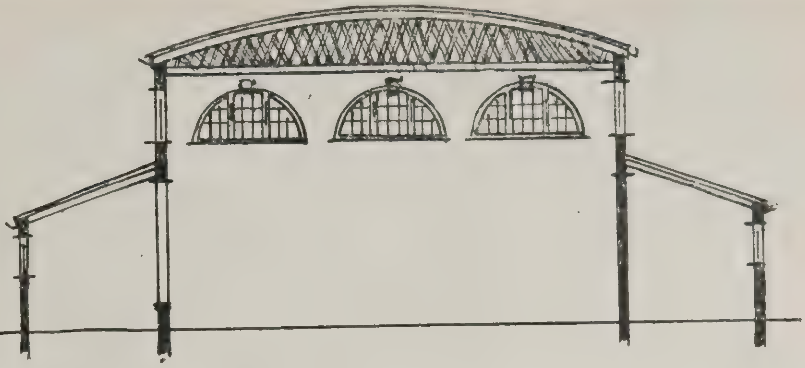

FIG 3.—SECTION SHOWING FORM OF ROOF SUITABLE FOR A ROLLER SKATING RINK.

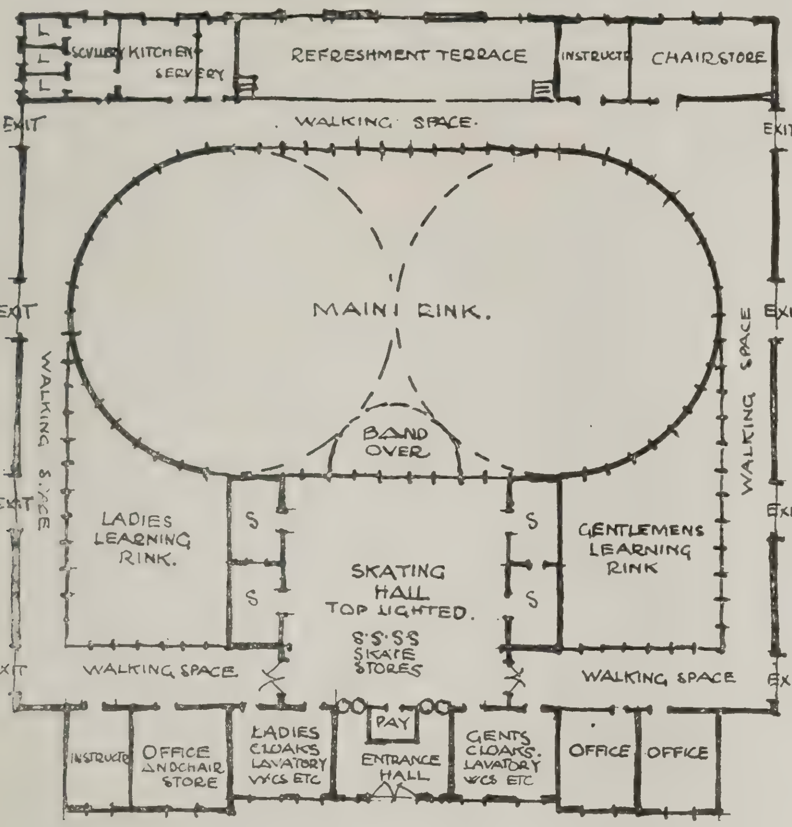

FIG 4. PLAN OF A ROLLER SKATING RINK NOW IN COURSE OF ERECTION IN A PROVINCIAL TOWN.

The more modern method of laying the floor is as follows. An ordinary floor is laid upon sleeper walls, the boards being placed diagonally, and the maple flooring laid on top of this. Rather wider floor boards are used than those previously mentioned, those now used being about 2½ to 3 ins. wide by 1 in. thick. These boards are tongued, grooved, and rebated, and secret nailed. The boards are laid straight in the centre, and follow the curves of the rink in diagonally-laid sections. It is to be remarked that there seems no reason to dispute the undoubted superiority of wide boards over the narrower battened floors used. It will in that case be necessary to provide effectually against the likelihood upon the part of the wider boards to shrink or turn up.

Reverting to a consideration of the plan in Fig. 1, we find that two annexes are provided to the rink for the convenience of the beginner, one for ladies and one for gentlemen, with an instructor's or supervisor's room between them. It is a radical mistake to provide the learner's annexe in the general hall, for learners, and especially those of the fair sex, are not encouraged by having to execute their probationary antics in the public view.

The panic and other exits should be governed by the rules pertaining to theatres and public halls of a similar description. Those now in use by the London County Council can be obtained from the London County Hall, Spring Gardens, London.

Pay office, ladies' and gentlemen's cloakrooms, attendant's room, and skate store are all provided at each side of the turnstile entrances. It is of great importance to ensure for instructors and attendants adequate supervision, and, in a good permanent structure, provision should also be made for a resident caretaker.

Figs. 2 and 3 show the best forms of roof and general construction. A curved lattice or bowstring roof, as in the one at Cardiff (Fig. 3) is greatly used, but the author pre-

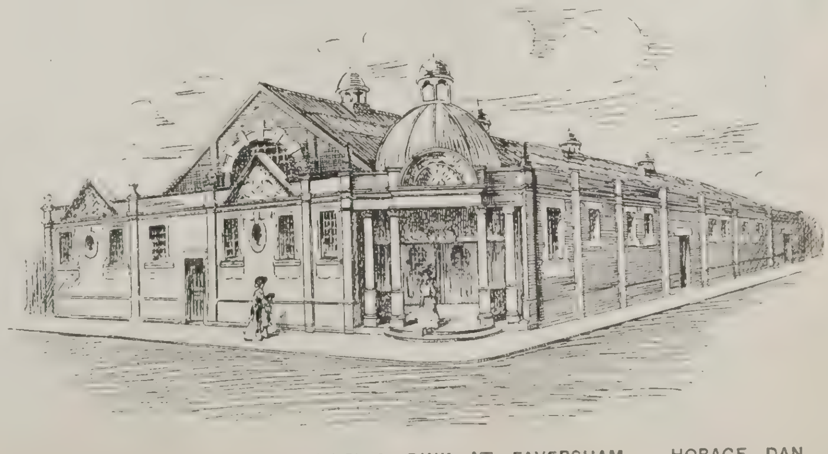

FIG 5.—ELEVATION OF A ROLLER SKATING RINK AT FAVERSHAM. HORACE DAN, M.S.A., ARCHITECT

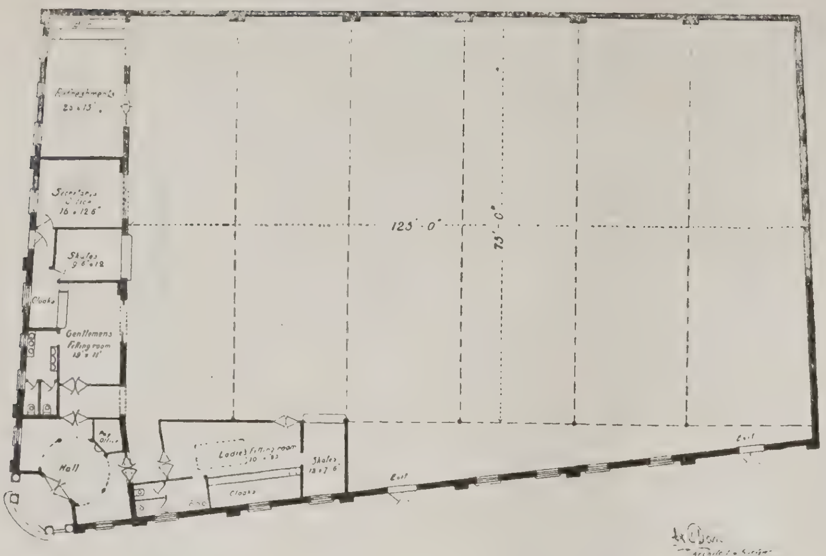

FIG 6.—PLAN OF ROLLER SKATING RINK AT FAVERSHAM HORACE DAN, M.S.A., ARCHITECT.

fers an ordinary iron roof of the type shown by Fig. 3. The bowstring roof would comprise three sets of timbers, these including the curved built up principal rafter, the tie-beam, and also the lattice struttings.

The principal would be double, and made up in short lengths of 4 in. by 1 in. scantlings cut to the curve. The lattice struts, 4 in. by 1 in. also would come in between the double principal, and also the double tie-beam, the latter, however, being out of 7 in. by 2 in. deal, properly broken and lapped at intervals.

The lattice struts will be about 1 ft. 6 ins. to 2 ft. centres and the whole will be well spiked together. Trusses of this description would be placed about 10 ft. centres, with a herringbone strutting in between.

The camber for the roof proper would be 6 ft. for 50 ft., and other spans in proportion, while the camber for the tie-beam would be 4 ins. for the same span. The roof could be curved corrugated iron sheets carried upon purlins in the usual manner, and it is easy to arrange for a ventilating ridge in the centre.

In Fig. 2 the rink should be clerestory lighted, except at the ends, where it may be considered desirable to arrange over the common rooms a spacious gallery for spectators. The side rooms can be roofed with a lean-to or flat roof.

The lighting is a point of vital and considerable importance. Most certainly it should not be by means of top lights proper, as the sun makes a building of this description too hot. Large semicircular clerestory windows, as shown, are much the best, and at the same time the most effective. Otherwise it may be as well to add to these clerestory lights some ranges of dormers in the main roof. The unsightliness of this main roof can be helped by arranging for a proper draw-curtain ceiling, fixed in a thoroughly adjustable manner between the principals.

The height of the section should be ample, and a definite scheme of ventilation should be adopted. All clerestory and dormer windows should be arranged to have a large portion to open by means of adjustable gearings. Artificial lighting will be electric arc lamps properly disposed, being suspended from the main roof principals.

Fig. 4 represents an important rink now being erected in a large provincial town, while Figs. 5 and 6 show another rink at Faversham, of which the architect is Mr. Horace Dan M.S.A., of Enfield. The Faversham rink, it will be seen, presents the difficulties of a corner site, while the other is upon an entirely open site. The chief feature comprised in this plan is the entrance, which is by way of turnstiles situated each side of a pay office, and giving entrance on to a large skate hall provided with chairs where skaters will put on their skates, and those not having their own may hire them from the skate stores at each side. The skate hall gives entrance to the rink proper, and the walking space around is to be used for emergencies and not for putting on skates. In some rinks it is customary to control the skating by means of a large illuminated changing notice. Thus the superintendent might for one period have "Ladies Only," then perhaps "Couples," then again "Gentlemen Only," then "Skate Slowly," "Stop," etc. This is the intention in the plan under notice, and consequently the space around the plan is so arranged that people can have speedy access through the open post and rail barricade.

The learners' annexes (ladies and gentlemen's) are off the main rink at each side, and though given a certain amount of privacy, they themselves can also watch with good effect the more skilful skaters upon the main rink. The rest of this plan is self-explanatory, though attention is drawn to the excellently arranged panic exits. It is also to be mentioned that all doors should, of course, open outwards, and be fitted with good panic bolts. It is possibly the intention in this plan at some portion of the day to devote one of the learners' annexes to the purposes of a prize tournament for figure skaters, and of general fancy skating.

A word about the (more or less) open-air rink. There is an exceptionally good one at the White City, Manchester, the huge rink being covered on top but left open at the sides. The plan (Fig. 4) shows roller shutters at the sides, so that in hot weather the whole of one or both sides can be advantageously opened up.

It is to be regretted that in numerous buildings of this character too little attention has been devoted to the elevation. Such a building demands unusual treatment, and no little skill is required to make the relationship of its various parts architecturally recognisable. The design of better-class public baths seems to offer a suitable precedent for effective though somewhat expensive treatment. Where stone cannot be used, however, dignified and excellent effect might be obtained from the use of rough-cast and brickwork. The sketch elevation shown by Fig. 7 explains the author's ideas and suggestions in regard to these points. Here cement rough-cast is plentifully employed together with some brickwork in the form of plinths and piers. Stonework need only be used in a very limited degree, but it would seem to the writer that such a building might be easily and effectively treated with some decorative tile-work of a good character, and in the sketch under notice some colour has been suggestively introduced in this manner. The brickwork will be carried out in a blue glazed brick, relieved with green at places. This will harmonise well with the grey of the rough-cast surfaces, the green roofs, and the white painted woodwork.

Speaking at the ordinary general meeting of the London and Provincial Bank on the 19th inst., Sir F. G. Banbury, M.P., who presided, said that he believed that the cement and brick trades were never in a worse position than they were in at the present moment, and the iron trade was bad.

* * *

The governing body of Worksop College, Nottinghamshire have decided to extend the present accommodation. The new buildings will include a science block, drawing and music rooms, a dormitory, library, masters' rooms and class rooms. The chapel will also be built at the same time. The work has been entrusted to Sir Aston Webb, R.A.

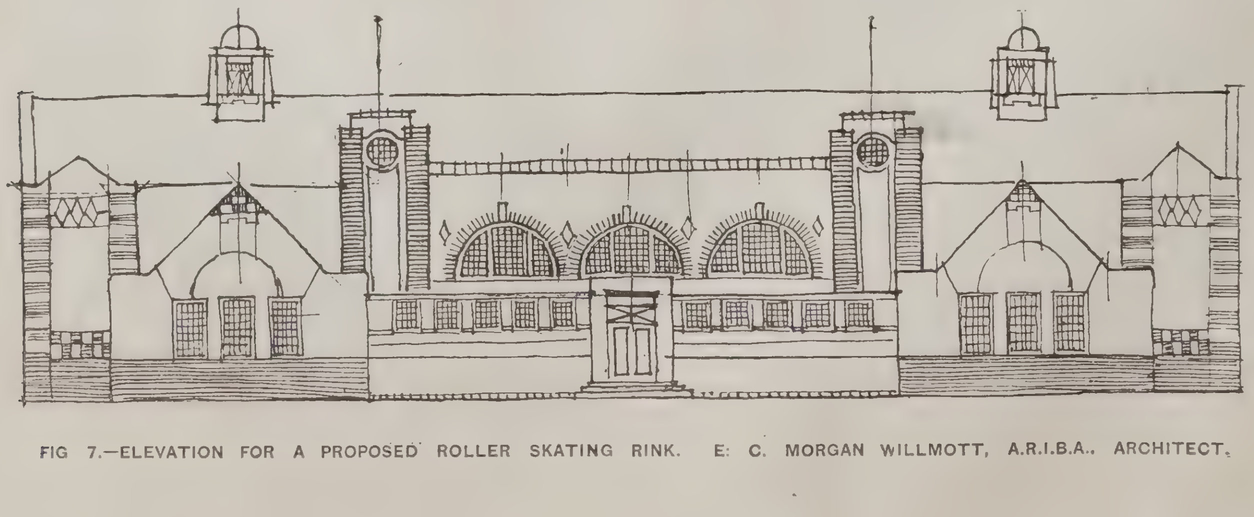

FIG 7.—ELEVATION FOR A PROPOSED ROLLER SKATING RINK. E. C. MORGAN WILLMOTT, A.R.I.B.A., ARCHITECT.

PAINT BLISTERING: ITS CAUSE AND CURE.

No question concerning defects in house painting is asked more frequently than this: "What is the cause of paint blistering?" And it is somewhat remarkable to note that, in perhaps nine cases out of ten, the fault is attributed to low grade or adulterated materials, although, speaking broadly, one might say that this is never the real cause. If we were to use for example, a white paint composed of 80 per cent. barytes and 20 per cent. of white lead, it might or might not prove durable, but it certainly would not blister unless—and here we reach the root of the matter—too much oil were used in mixing it, and other adverse conditions existed; but, given the same conditions, blistering would result just the same if the finest pure white lead had been employed. From this it will be seen that the pigment as a rule had nothing to do with the trouble. It should be said at once that there are many conditions in house painter's work, some of them totally different from others, to which the grave defect of blistering may be attributed. But there are three which occur much more frequently than any others, and to these we will first direct attention. They are (a) improperly mixed paint; (b) improper application; (c) moisture. The first of these causes has been already mentioned. If too large a proportion of oil is used in a paint, blistering is very likely to occur, even though the very best materials have been employed. Indeed, it is said that an architect, being struck with the fact that turpentine entirely evaporates, specified that the paint on a certain job should be made of pigment, linseed oil, and driers only, without any turpentine being used at all. Of course, the result was a fine display of blisters on every part of the work. Turpentine, as a matter of fact, plays an important part in painting, because it permits of the paint being applied in very thin coats, and when this is done the risk of blistering is greatly reduced.

Under the head of the application of the paint we had two important defects which are often met with and both of them contribute largely to blistering. The first is that too much paint is applied, or, as the painter would say, the work has not been sufficiently "brushed out." An inexperienced painter will almost always use far more paint than he should; he "slobbers it on" instead of "brushing it out." The rule in applying oil paint is that it should be used as though it cost a guinea an ounce, or as if there was evidently not sufficient paint to complete the work and an effort was made to stretch it out, so to speak. Within reasonable limits, then, the less paint actually put on in each coat, the less likely is the liability to blister. At the same time, it is necessary that the coat be sufficiently thick to hide the surface to which it is applied—in other words, to retain its "body" or opacity.

From what has been said, it will be seen that when work is particularly prone to blistering, extra thin coats should be applied; although this would probably not prove of much advantage if the cause of the blisters was moisture. But on ordinary dry wood several thin coats (even omitting the oil altogether, but adding a little goldsize to bind the particles together), will usually effect a cure. Such coats will dry "flat," or without gloss, but this can easily be remedied by varnishing, or, if this is too costly, adding a little varnish to the final coat of paint.

Another reason for blistering is that there is not sufficient adhesion between the several coats. There is a popular delusion that it is necessary that one coat should be thoroughly hard before another is applied, but this is quite wrong. Let the reader carefully examine some blistered paint work—let him break one of the blisters, and he will be almost sure to find the priming quite intact underneath. Now, if, as commonly happens, an excess of red lead were given to the priming, it would quickly dry very hard; and if an oily coat were applied, perhaps too liberally, on top of it, there would be no union between the two coats, and blistering would, under the influence of the sun, be nearly certain to result. Sometimes ochre is used for priming; and as this dries very hard, the same result is often brought about. If, however, each coat of paint is applied when the one underneath has not become quite hard, a key will be formed, especially if the coats are mixed alternately "sharp" and "oily"—i.e., with little or no oil in every other coat. Bearing on this subject, a useful experiment may be performed, which is to give a good round coat of oily paint to a piece of slate, and, when this is quite dry, exposing it to the action of the sun. Blistering is certain to result.

It should not be imagined from what has been said above that it is advisable to give one coat of paint upon another that is not fairly dry. When this is done, blistering is very likely to occur. The point is that the undercoat should not be very hard.

The second great cause of blistering is moisture. This may arise from imperfectly seasoned timber, which is always liable to this defect; for it must be remembered that if the paint is applied to timber that is not quite dry when a house is erected, the sap contained in the wood is locked in, so to speak—has no chance of drying out—and hence will be drawn by the sun, and almost invariably cause blistering. Quite frequently, however, in old houses, paint-work will be found to blister, although the fault has never appeared before. In this case close investigation will probably show that a defective gutter, or something of the kind, has caused dampness, which enters the wood and gives rise to the trouble. Quite frequently painted work which is in other respects perfect will be found to blister around the knots. This is due to the fact that there is usually a good deal of resin in the knots, which causes trouble, and the usual plan of applying shellac over these knots to prevent the exuding of this resin may, under certain conditions, give rise to blisters, because shellac does not afford a very good key to the paint; and hence it is that some painters prefer to give the knots a mixture of red lead and glue, or of silver or gold leaf.

As to the remedies for blistering, of course the best remedy is as far as possible to avoid the cause; but in obstinate cases there are two remedies which may be tried. The first is to burn the paint off to the wood, or to use one of the liquid paint-removers, which are now becoming so popular. Then give four to six coats of paint, according to the finish required, each coat to be mixed quite flat—that is, without oil, but with the addition of a little goldsize. If six hours is allowed between each coat, it will be sufficient, because these turpentine coats dry very quickly. Of course there will be a little oil in the mixture, as the colours which are to be used are those ground in oil; but the coats will be exceedingly thin, and will dry without gloss. A little gentle rubbing down between the coats is desirable, and the work is finished with a coat of good varnish. If it is exposed—as, for example, in the case of a front door—special "front-door varnish" should be employed. This method is similar to that followed by carriage builders, who obtain such beautiful results in their work.

Another and in many respects a better plan is to use a good washable water paint, and this almost invariably effects a cure. It is very inexpensive, and the writer has known many cases of woodwork exposed to the sun which has blistered for years, the blistering finally having been cured by using a couple of coats of washable distemper with one flat coat of paint over; then an ordinary coat of oil paint or a coat of varnish as may be desired. This method cannot be too widely known; and if the reader will experiment, he will find that he will probably be as much gratified at the result as the writer was when he first tried this method.

J.

THE BUDGET AND BUILDING.

A Contractor's Opinion.

Mr. Samuel Chapman, Unionist candidate for Perth, has received the following letter from Mr. John Anderson, of the firm of P. and W. Anderson (Limited), masons, builders, and public works contractors, Glasgow, who, in conversation with Mr. Chapman, informed him that the firm (which employs more men than the whole of the other Glasgow builders) were on the point of buying a large extent of land for building purposes, but after considering the effect of the Budget proposals had given up the idea, and bought Consols instead:—

Dear Mr. Chapman,—Referring to my conversation with you, I hope the electors of Dumfries Burghs realise the serious effect the Budget proposals would have on the building trades. As you are aware, Dumfriesshire stone is used all over the country, and the prosperity of the quarries depends entirely upon the demands from the large towns throughout Scotland. The increased taxation will certainly put a stop to investors placing their money in property, which at the moment is almost unsaleable, the increased taxation making it quite prohibitive as an investment. The building industry, upon which the prosperity of Dumfriesshire so largely depends, will thus receive a serious check, resulting in the further closing down of quarries and a large increase of unemployment. The taxation of land will not increase building under the proposed new conditions. In fear of further taxation, the investor will not hold land at any price. Supposing, however, a landowner is prepared to sell at a very low figure, his difficulty would then be to find the investor who would build on it, owing to the increased burdens placed on property. Irritating as the proposals of the Budget are, the situation is seriously aggravated, for, according to Mr. Keir Hardie, "If the Labour party in the House of Commons had been twice its size, the tax would have been twice as big." The absurd proposal of taxing increased value, and the large addition to the fees for transferring property and creating bonds, etc., simply prohibit all enterprise. The result will be the transfer of capital to foreign investments that will not be subject to those provocative charges, and in this way it will be the working man that will suffer most.—Wishing you success, with kind regards, yours faithfully, John Anderson.

The Dulwich Estates.

Referring to the reply of Mr. E. T. Hall, F.R.I.B.A., last week, Mr. Evan Spicer, L.C.C., writing to "The Daily News," says that "I cannot help feeling, from my personal knowledge, that the governors are proceeding on the right lines in the best interests of London. I would strongly urge that nothing should be done with their uncovered land to force houses upon the market until they are actually required. At the present moment I think it is of far greater importance to the health of London that all open spaces within five to six mile area should be retained as long as possible for the benefit of those residing in that district. The London County Council are, I believe, at the present moment seeking for ground suitable for playing-fields, and it is not an easy matter to find. . . . My firm conviction is, therefore, that open spaces, say, within a radius of six miles of London, are far more valuable to our young people in the interests of health and general well-being than if they were covered with houses."

The British Constitution Association Deputation to Mr. Lloyd George.

The memorial presented to the Chancellor of the Exchequer by the British Constitution Association on the 20th inst., contained the following clauses of particular interest to builders:—

(4) In practice the taxation of increment value would lead to extraordinary anomalies and injustice. For instance, Land Companies which buy land wholesale and sell retail are engaged in the very work of development which the Finance Bill professes

to assist; yet as the Bill is framed the plots into which, as part of their business, they divide the land, would, while they remained unbuilt on, be subject to the duty of ½d. for every pound of their capital value—which would be in effect to tax a tradesman on the stock which for the time being he had on hand and was unable to sell—in other words to penalise him for trading in land.

(5) Again, land cannot as a rule be placed on the market without considerable current expense for management, office rent, surveys, road-making, advertisements, auctions, etc. For payment of these expenses and for providing interest on capital borrowed, and dividends on capital subscribed, practically the only source to which a Land Company can look is the difference between the book value and the selling price of the land in which it deals. Of that difference the Bill proposes to confiscate one-fifth, leaving four-fifths out of which the whole of the administration expenses are to be met, and the losses incurred in lean years made good. It is not too much to say that, unless the sales are much more rapid and remunerative than is usual, no dividends would under these circumstances be paid by a Land Company—that most existing Land Companies would be absolutely ruined—and that this form of enterprise would become a thing of the past.

(10) One of the professed objects of the Bill is to increase building and cheapen houses. The proposed Reversion Duty would operate the other way. It is too often forgotten that the supply of new houses depends in the main on the operations of the enterprising builder who puts up buildings for which he thinks there will be a demand, and takes the risk of the market.

(11) It is quite unusual for the man in want of a house to build the house for himself. The building-lease system suits the enterprising builder because it does not involve a lock-up of capital in the purchase of the fee simple. A Reversion Duty which would tend to increase the ground rents demanded and make owners more reluctant to grant such leases would clearly discourage builders, who would also of course be discouraged by the Increment Duty.

(13) The proposed legislation would introduce complications and increase costs in connection with the purchase, sale, and leasing of land, and is entirely opposed to the principle of free trade in land. It appears to be based on the idea that unearned increment on land is "regular, normal, and progressive." This is very far from being the case. The value of land, as of other commodities, goes up and down, and though on the whole and in the long run there may be an increase, yet in large districts and for long periods there is often a steady decline.

(14) The valuations and revaluations suggested in the Bill would cause endless trouble, inconvenience, and expense, and could never be put on a satisfactory footing.

(15) The immediate effect of passing the Bill would be to depreciate the capital value of nearly all interests in land, probably to an extent much greater than would be shown by strict actuarial calculations.

Among the speakers who addressed the Chancellor were Lord Hugh Cecil, Mr. Herbert Michell (British Land Co.), Sir William Chance, Mr. Edward Bond, Mr. Edwin Evans, and Mr. George Hubbard, F.S.A. (Royal Institute of British Architects), who said he had been appointed by the Council of the Institute, which consisted of some 3,000 members of the profession practising in all parts of the country. They felt the proposed land taxes would be unjust to a large section of the community, and would specially injure all industries in any way connected with building.

Mr. G. A. T. Middleton (Society of Architects) said that the body on whose behalf he appeared contained some 700 architects practising in Great Britain, and that the Council of that body viewed with considerable dismay a proposal which, so far as they could see, would have a deterrent effect upon building operations. He desired to associate himself with all that Mr. Hubbard had said.

Mr. Alex. R. Stenning (President of the Surveyors' Institution) was unavoidably absent, and the remarks he would have made were handed in. In the statement Mr. Stenning said: The valuation of large estates in which villages, railway stations, and perhaps the suburbs of large towns form part, was no small matter. It was most important that the first valuation should be done with special care; this would take a lot of time to work out, and the cost of making such a valuation would amount to a large sum of money even if done on the most moderate terms. If a valuation was considered necessary for the interest of the community surely the cost of such valuation should be paid for by the community. He did not think fifteen millions sterling would be an unreasonable figure for the valuation which the proposed land taxes would involve.

The Chancellor of the Exchequer, after complaining that the speeches to which he had listened consisted mainly of the sort of political arguments which he had heard for months, said that the advantage of deputations was that they enabled Ministers to hear at first hand from the persons interested what their view was. There were gentlemen there who could give him invaluable facts, but this they had not done. They had the whole of the facts at their command, and if they could demonstrate that any part of the Bill was unworkable or inequitable, or unjust, he invited them to send these facts to him, and they should receive his careful examination.

In addition to the architects who spoke, Messrs. Mark H. Judge, Max Judge, Percy Leeds, F.R.I.B.A., R. M. Lucas, F.R.I.B.A., and Percy B. Tubbs, F.R.I.B.A., were also present.

Correspondence.

The Editor declines responsibility for the statements made by correspondents.]

The Building Trade and the Budget.

To the Editor of THE BUILDERS' JOURNAL.

DEAR SIR,—With reference to the article in this week's issue of your paper, I can hardly think that any builder who understands the present condition of matters as regards land and houses, and who has taken the trouble to familiarise himself with the details of the Budget, can believe that if passed into law the Government's proposals will hurt the building trade. The items culled from Unionist papers as to projected jobs being dropped may be true enough, but this is a matter of every day occurrence. Some of it may be due to the same spirit which prompted the trust magnates in the United States to upset matters when Mr. Roosevelt was endeavouring to effect reforms. A portion of it is doubtless due to the uneasiness that has been engendered by interested politicians and the landed classes in the minds of the lay person. This uneasiness has hurt the building trade for many years, and in the best interests of the trade, Mr. Lloyd George's proposals, which are of an extremely mild character and would do little harm to even the landed interest, should be allowed to pass. The question has been before the country too long; and the principle of taxing land values has been approved over and over again in Unionist Parliaments, and by almost all the municipalities in the country. Besides contract work, I have myself built during the last 12 years almost two thousand houses, and I have never been able to see that the building trade was helped by the landlords making me pay up to two hundred pounds per annum per acre for virgin ground that was formerly let to farmers at not more than two pounds per acre. The whole agitation is for the purpose of relieving buildings of the whole or part of the burden of local taxation which lies on the back of the building trade. Here in Glasgow and many places are in a worse plight, any one using twenty shillings' worth of the products produced by me has to pay six shillings and eightpence in taxation, and if this is the way to encourage the community to make use of buildings or to expend money on producing them, then logic is indeed dead. Local taxation cannot all be planted on the land; but some of it can, with the additional advantage of reducing the power of the landlord to exact exorbitant feuing rates. Other portions can be levied, as in some towns in Germany, by means of an income-tax; and this would ensure that the unmarried workman sharing half of a room would pay at least equally with the married workman who must needs have housing accommodation for his family. A national movement to relieve housing accommodation of local taxation would have enormous driving power behind it; and the result would cause such a boom in the building trade as has never yet been seen. What do builders think?

Yours faithfully,

JOHN A. MACTAGGART.

[The insertion of this letter—which is perhaps rather too strongly tinged with political preference to be entirely suitable to the columns of a trade journal—will, we trust, be taken as an evidence of our desire that both sides should be heard on a matter that seems to us to be of vital importance to architects and builders. We urge readers who may feel disposed to reply to it, to keep as clear of political allusions as the circumstances will admit. The "Builders' Journal" is not an organ of political opinion.—ED.]

Plaster Prices at Manchester.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—It may be interesting to note the low prices at which work is being actually taken in Manchester suburbs for plastering six-roomed houses. The following are low ordinary prices:—324 yards two-coat plaster walls, at 6d. £8 2s.; 120 yards two-coat lath and plaster ceilings, at 1s., £6; 80ft. molded cornice, at 4d., £1 6s. 8d.; 35ft. cement skirting, at 3d., 8s. 9d.; pointing windows, 5s.; beam (panelled) with caps and trusses in hall, 10s.; total £16 12s. 5d. The above work, valued by us at £16 12s. 5d., is being done at £8 per house.

J. B. JOHNSON AND CO.

Liverpool.

TIMBER WHARF AND DOCK CONSTRUCTION.

By Hugh Cregeen, A.M.I.C.E., P.A.S.I.

The following types of timber wharf construction may be useful to contractors.

Some of them are in use in various places in this country at the present time, and they have been erected instead of permanent and solid structures on the score of economy, and so may be recommended for temporary purposes.

Figs. 1 and 2 show the cross section and elevation of a loading wharf for stone traffic alongside a railway siding, standing 7ft. above rail level, to enable carts of material to be tipped direct into wagons without the additional expense of handling by manual labour.

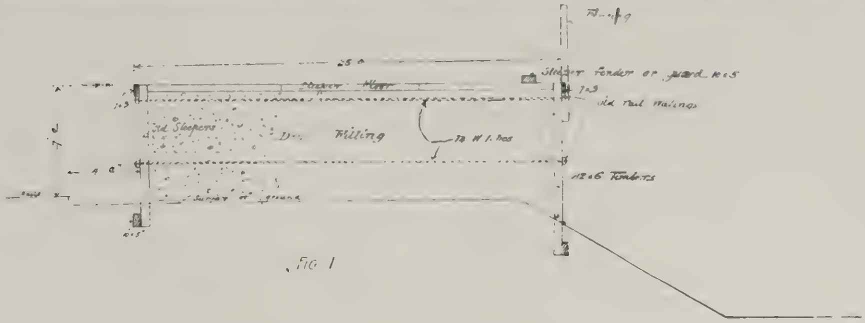

FIG 1

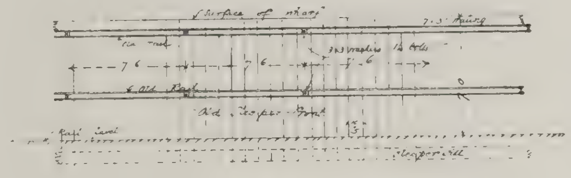

Fig 2

The dock is constructed thus:—Sound second-hand creosoted sleepers 9ft. long, and in section 10ins. by 5ins., are placed on the ground to a depth of about 2ft., and these are secured by tie rods 1¼ins. diameter passed through old steel rail walings in a double row, spaced 7ft. 6ins. apart and run through from front to back of the wharf. The back wall being necessarily deeper on account of the bank sloping down, 12 by 6 timbers about 11ft. long are substituted in place of sleepers. Good dry filling material is then carted up and tipped in between the two walls until the top level is reached, a ramped incline leading thereto, and after the whole has consolidated, a corduroy or sleepered roadway is laid, on which the traffic is carried on.

A fender rail timber is spiked down all round the roadway as shown, and a substantial fence outside renders the use of the wharf safe for carts.

The whole of the outside surfaces are afterwards tarred and the railing painted, thus rendering the life of the structure as long a one as is possible with timber.

An approximate estimate of the cost of such a wharf 200 feet in length and taken exclusive of the incline approach would be:—

	£	s.	d.
318 old sleepers, 10 by 5, fixed in wall, at 2s.	31	16	0
720 ditto, laid in floor, 1s. ...	36	0	0
2,100ft. run creosoted timber at back, 1s.	105	0	0
62ft. cube timber in longitudinals, and fixing, 3s.	9	6	0
283 yards run old steel rails, drilling and fixing, 2s. 6d.	35	17	6
75 yards run fencing at back of dock, 7s. 6d.	28	2	6
3¾ tons W. iron ties, £17 ...	63	15	0
Spikes, etc., say	3	10	0
1,390 yards cube dry filling, 2s. 6d.	173	15	0
Tarring and painting	12	0	0
or about 50s. per ft. run.			
	£499	2	0

Figs. 3 and 4 show a type of heavy timber wharf construction carried out at a dock made on land reclaimed from a river bank, in order that barges might be moored alongside and unloaded. The description is as follows:—

A double series of whole timber pitch-pine piles were driven into the river bed until firmly secured, each bay being about 9ft. 4ins. apart centre to centre, after which 14 by 14 longitudinals, five in number, one below the other, were inserted and bolted through from the piles. Against these, in front, sheet piling of 14 by 7 stuff was driven and secured by means of waling pieces, bolted at each alternative sheet pile with 1⅛in. bolts. The main piles in each bay were as an additional safeguard, held back as shown on the section by means of 2in. tie bolts fastened to land tie piles 14ins. by 14ins. driven into the bank at a distance of about 24ft. from the face line of the wharf.

The main front piles were continued up about 2ft. above the surface level of the wharf to act as bollards or mooring posts, and fender timbers 12ins. by 6ins. in size were spiked on the outside as a protection to the piles from the rubbing of vessels moored thereat.

The ground was, after the completion of the timberwork, filled in with dry material and a layer of block chalk 2ft. thick placed immediately behind the piling to assist drainage, after which the surface of the wharf was finished with metalling.

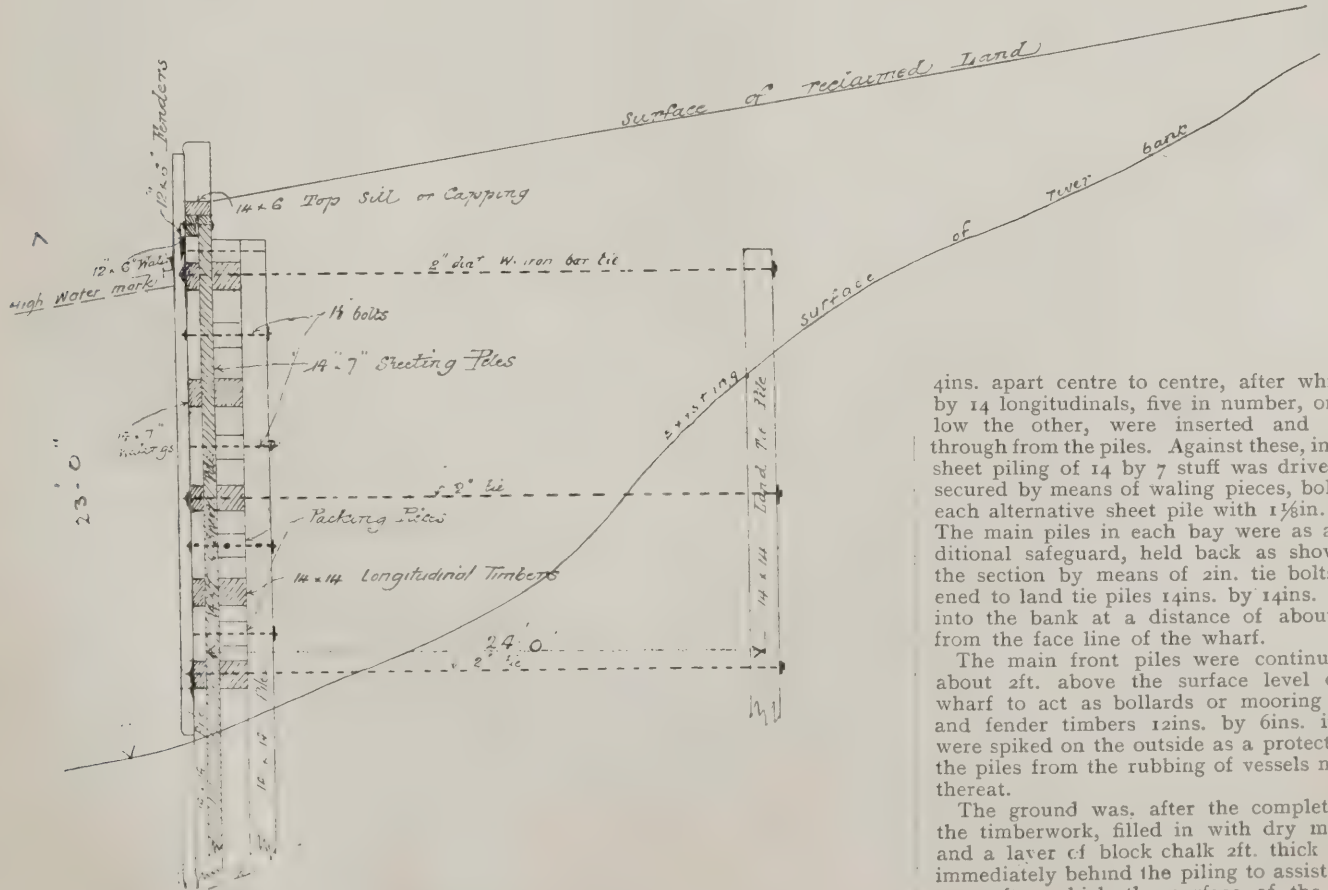

FIG. 3.—HEAVY TIMBER WHARF CONSTRUCTION.

This wharf was carried out at a dock made on land reclaimed from a river bank.

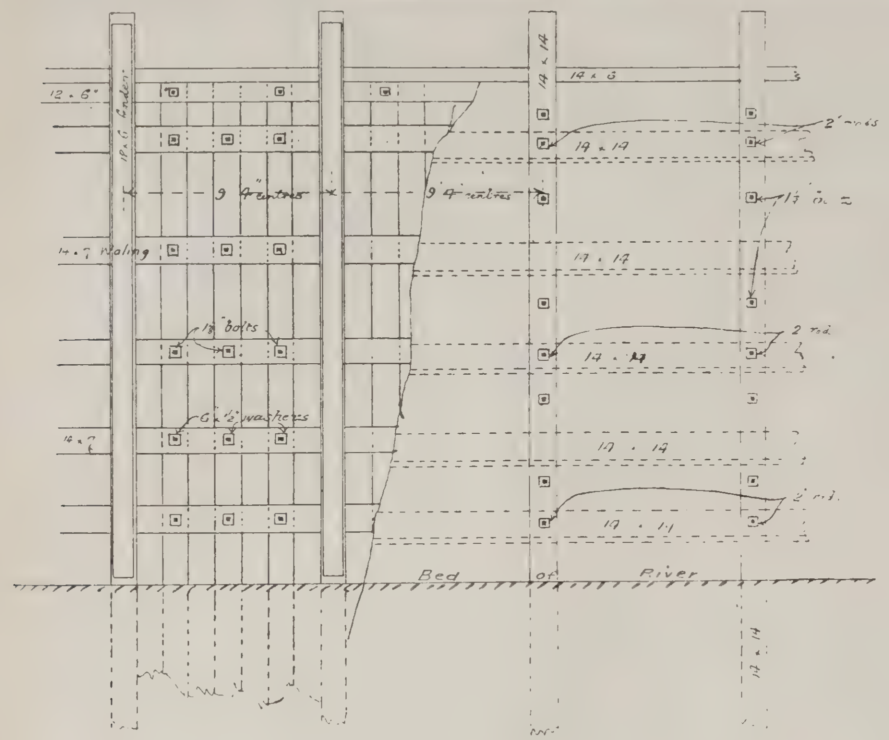

FIG 4

Fig. 5 is a section of a small wharf front constructed of old sleepers, at which barges can unload at various states of the tide, there being two levels one below the other. The sleepers are secured by iron tie rods, passed through 11 by 5 walings and connected with land ties.

Figs. 6 and 7 are a section and elevation respectively of a shallow dock adjoining a railway, and is 3ft. above rail level. This also is made out of old sleepers, which are driven in as uprights at 4ft. 6in. intervals, and five rows of the same material are fixed behind these, the whole being as in the last type, tied back by means of 1½in. tie rods to land ties.

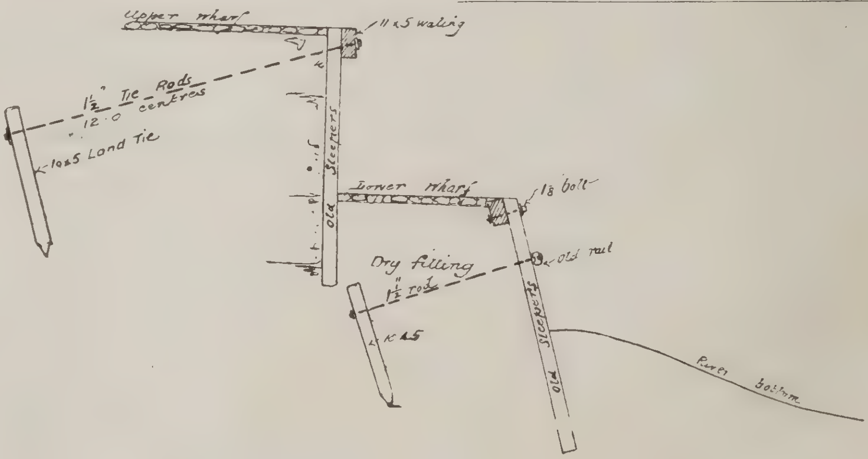

Fig. 5

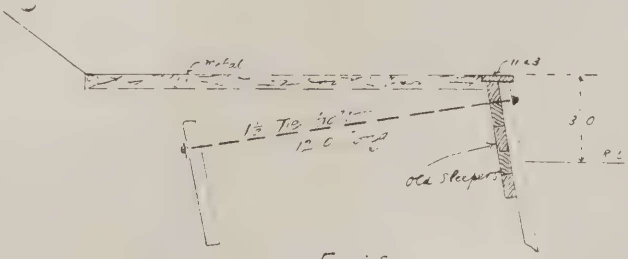

Fig 6

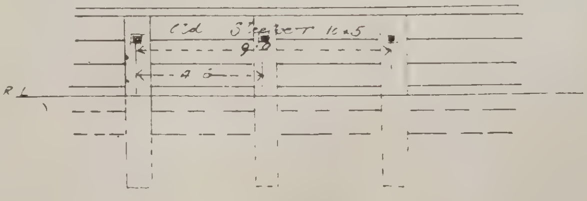

Fig 7

TIMBER WHARF AND DOCK CONSTRUCTION.

Our Plate.

House at Rowledge near Farnham.

This house is erected upon a very pleasant and well-wooded site. The walls are externally covered with rough cast and the roof with old tiles; the arrangements generally are convenient and modern. The hall, from which a pretty view of the garden is obtained, extends the full depth of the house. The drawing-room and dining-room and one bedroom have spacious bay windows. The work was carried out by Mr. A. G. Mardon, of Castle-street, Farnham, and the architect was Mr. Arthur J. Stedman, of South-street, Farnham.

"High Hedges," Studland Bay, Dorsetshire.

This house was erected on slightly sloping ground at Studland Bay, a place far famed for its beauty. The design was greatly influenced by the desire to command the delightful views of the bay and Poole harbour over the tops of the surrounding trees. The accommodation includes dining-room, drawing-room with alcove and study, four bedrooms on 1st floor, with bath-room, linen, etc., and 4 smaller bedrooms on the top floor. The walls are hollow and roughcasted, and with dark red tiles for the roof. The garden is weather boarded, with tile roof, and the woodwork is treated with Solignum. The contract for the house was only £612. The builder was Mr. Geo. Hardy, of Swanage, and the architect, J. E. Mundell, A.R.I.B.A., P.A.S.I., of 157, Wool Exchange, London, E.C. and Poole, Dorset.

PRACTICAL CONCRETING.

(*Continued from p. 57, No. 754.*)

It is important in measuring that the boxes should be filled; an inch too much of the large box and an inch too little of the small one will make all the difference between a good or a bad gauge, and must be avoided. A common practice of foremen is to have the aggregate stored round the mixing platform, and if the latter is only just sufficient to hold the whole contents of the gauge, in mixing and turning over, the gauged part frequently comes perilously near the ungauged portion, and unless the clerk of works keeps a close look-out, shovelfuls of the latter will be added to the former, to the loss of the true proportions as specified. This the clerk of works can remedy or avoid by seeing that a clear space is left all round the platform, or if the site is too cramped to allow of this, then scaffold-boards or running planks can be stood on edge to separate the two classes of materials. The mixing platform is easily formed of scaffold or other boards of the same thickness.

6.—Mixing.

Mr. C. H. Colson, an engineer of great experience, once said at a meeting of the Society of Engineers, "It has been the habit to value Portland cement concrete from the point of view that no skilled labour was needed in its preparation; that it was a material of so simple a character that any man who could use a shovel could mix it; was this correct? He believed that the more

UNIVERSITY OF ILLINOIS

skill and thought exercised in the manipulation of concrete the more satisfactory would be the result. The mixing was often left to the care of men who had no feeling of interest in the matter, and therefore cared but little whether the mass was properly mixed or not."

As a matter of fact, in addition to the exact proportioning of the materials, the mixing itself requires close supervision. The platform should be well stiff-broomed prior to receiving the first of the ingredients, at each gauging, to free it from all loose dust, dirt, or soot. The aggregate should be watered if composed of broken brick or stone or similar porous substances, to avoid their soaking up the water required proper to the mixing. When one gauge has been brought to the platform, it must be turned over at least twice a day, before any water is added, which should be through the rose of a hose-pipe, or, if a large supply tank is near at hand, a watering-can with rose may be used, but there is always a risk of the "turners-over" continuing their work whilst the can is being replenished, so that some parts do not receive their proper share of water; on the other hand, if a hose-pipe is used, it must have a "waste-not" cock at the rose end to allow of the man manipulating it checking or stopping the supply to avoid saturating and drowning the mixture. The turning over whilst wetting forms the third turning; it should be turned over at least once more before being wheeled away to be deposited—twice for preference.

Method is necessary in the application of concrete as in most other matters. Whatever the concrete is to be used for—foundations, walls, floors, roofs, or any other purpose—equal care is necessary. When mixed by hand the desire on the part of many is to perform the operation as unsystematically as circumstances permit. It is unattractive work—about equal to that of mortar making—and unless proper care is insisted upon, amalgamation of the materials is not what it should be.

In this connection it is interesting to observe the way in which concrete is often made, and by no means difficult to judge the occupation, in a general way, of the men employed in mixing; a bricklayer's labourer, more especially, if his work has been confined to mortar making, chafes the concrete with the end of his shovel after the last turnover; he cannot resist the habit he has acquired in mortar making; the result is that if the aggregate is brick *debris* or furnace ashes or anything of a comparatively soft nature, some portions get chopped asunder, and he has undone in a minor degree the entire coating of the aggregate with cement.

The navvy, on the other hand, after filling the barrow with concrete and before wheeling it away, pats it round the sides with the back of his shovel, as he would do sand, earth, or gravel, but for no purpose. Nor will either of this class of mixers, as a rule, give the materials the wrist twist so essential when the concrete is being mixed, but simply move it from one position to another, not turning it over, as is necessary to ensure amalgamation of the materials.

The R.I.B.A. Committee specify that in concrete mixing, and when the materials are mixed by hand, "they are to be turned over and thoroughly mixed on a clean platform until the colour of the cement is uniformly distributed over the aggregate."

Hand or Machine Mixing.

If the size of the job warrants it, a mechanical mixer can be used, which gives good results, and on large works the concrete produced is considerably cheaper in cost per cubic yard. The clerk of works still has to see that it is accurately gauged, etc.

The eminent engineer to the Metropolitan Board of Works (Mr. Grant), however, half a century ago made interesting experiments with a view of ascertaining which was the best way of mixing cement, by hand or with a mortar mill, with the result that at three months old the hand-made mortar was double the strength of that made by a mill, and at twelve months three times the strength. The result is curious and inexplicable, but is evidence that the manipulation of cement has a good deal to do with after effects. The mixing of cement is usually a happy-go-lucky process, and the difference in its ultimate value should astonish many people.

Strength.

The question as to which is the better, the wet or dry mixing of concrete, has been much discussed. Recently in Germany there were given out the results of extended experiments covering some four years. From these reports the conclusion is drawn that the smallest amount of water which produces a mixture suitable for ramming gives the *strongest concrete.*

The results of these experiments confirm that which other experiments, covering shorter periods of time, indicated, and will not occasion any surprise. At the same time the concrete worker who attempts to use the smallest amount of water which will produce a mixture suitable for ramming will find many practical difficulties.

Skilled Labour.

The great obstacle will be the difficulty of securing "skilled" labour. The degree of skill and care required with such a mixture is so great that the ordinary labourer cannot be entrusted with the work, and prices are being cut so low that to train men to perform this work is well-nigh impracticable.

In a brick pavement that was being torn up preparatory to relaying, the bricks had been grouted with a comparatively dry mixture of cement and sand. The result was that the grouting only went about one-quarter way down the bricks, and in less than two years the pavement had become so rough that it had to be relaid.

Other pavements were examined where the grouting had been done with a mixture that would flow readily and could be swept into the crevices. In this case the grouting completely surrounded the brick and the roadway was a solid pavement.

Not only does a wet mixture of concrete allow the employment of less skilled workmen, but it insures against the injurious effect of the varying amounts of moisture found in the material used.

Porosity.

The proportion of water used in mixing the material is of greater influence on the density of the mass than is commonly supposed by those who have little experience in the manipulation and use of cement. If the paste is too soft it does not bind properly, in spite of the assertions of some people to the contrary. The actual proportion of water depends on the volume-weight of the mass, and where waterproof concrete or cement is required care must be taken not to use more than is absolutely necessary, as an excess of water makes the cement too porous when set.

Aggregates and Temperature.

The compressive strength of concrete and mortar, as influenced by the proportion of water used, was investigated recently by Herr Brabandt, a German railway engineer. The test cubes were 30cm. (about 12ins.) on a side, and were made in accordance with the rules of the "Deutsche Betonverein." They were stored in a shed, under wet sand, and were tested after twenty-eight days. The test results showed a certain proportion of water which gave the greatest strength, either more or less water giving poorer results. The conclusions drawn by Herr Brabandt from his tests on concrete are as follows:—1. The most favourable quantity of water for the mixtures commonly used is about 15 to 20 per cent. of the volumes of cement and sand. 2. Poor mixtures need less, rich ones more water. 3. The moisture already contained in the raw materials must always be considered. 4. The absorption of water by the gravel, ballast, or broken stone must be taken into consideration. The quantity of water thus required must be determined beforehand by tests, and added to the quantity needed for the mortar. 5. In cold seasons less water, in warm weather more water must be used. 6. With very rich mortar mixtures, with more cement than sand, the amount of water demanded is considerable, and may even reach 30 per cent. 7. It seems wise to determine the amount of water by tests, at least when required for large buildings, and to regulate it by general specifications.

To attempt to specify with any accuracy the quantity of water needed is, however, impractible; it cannot even be stated approximately. The aggregate is, perhaps, of an absorbent nature or the reverse; it may be quite dry or very wet; it may be composed of coarse, or of comparatively fine materials. Each of these conditions affects the amount of water needed, and it is only by practice that the proper quantity can be ascertained.

(*To be continued.*)

Builders' Notes.

The members of the Stourbridge and District Master Builders' Association held their annual outing to Holt Fleet, via Worcester, on Tuesday, the 13th inst., and, in spite of the unsettled weather, a most enjoyable day was spent. Among the party were Messrs. C. Griffiths (president), T. J. Mason (vice-president), J. H. Willetts (hon. treasurer), J. Stokes (president Worcester M.B.A.), and P. D. Folkes (secretary), and a number of manufacturers and merchants connected with the trade. The sail up the river to Holt Fleet was thoroughly enjoyed, and luncheon was partaken of at the Holt Fleet Hotel, where, after the toast of "The King," Mr. Stokes proposed the toast of "The Association," to which Mr. Griffiths responded. Mr. T. J. Mason gave "The Visitors," which was responded to by Mr. T. Freer Ash (Birmingham).

* * *

The employees of Messrs. Want Bros., builders, of Islington, had their annual outing to Brighton. The party arrived at their destination in good time, and immediately embarked on motors for the "White Horse," Rottingdean, returning later to Brighton to the "Unicorn" Hotel for an excellent dinner. After dinner Mr. F. G. Want spoke of the success of the business, and hoped to meet all employees in increased numbers on the next annual occasion. The health of Mr. F. G. Want and prosperity to the firm was pledged with musical honours. Then followed a trip to Devil's Dyke, where tea was served, the party returning from Brighton in the evening.

* * *

A few of the residents of Sutton and the adjoining district recently formed a committee to develop on artistic Garden City lines an estate of thirty acres, known as "Elm Grove," in the parish of Wallington, just where it joins Carshalton on the London road. It is proposed that profitable development on a co-operative basis shall go hand in hand with artistic development; that the trees shall remain; that the river shall not be converted into an underground drain; and that those who live on the estate shall have fresh air in plenty, a plot of land to convert into a flower garden, and substantial and sanitary dwellings. The committee have the option of purchase for £7,500. Subscriptions for stock and shares in the company to be formed under the name of the East Surrey Tenants, Ltd., have already been promised to the extent of between £1,000 and £1,500. The loan stock bears 4 per cent. interest, and in addition to the land and houses there is the security of the shares (a minimum of £30) held by each tenant. Mr. D. W. Cooper, Endwood, Carshalton Park Road, Carshalton, is the hon. secretary of the movement.

* * *

Members of the Southampton Master Builders' Association had their annual outing on the 15th inst., when a party, numbering forty-five, proceeded to Reading by train, and had a trip down the river Thames by launch, the delightful scenery being observed under ideal conditions, as the weather was fine. At Henley the party partook of lunch at the Little White Hart Hotel, Mr. J. P. Beer, the president, occupying the chair, supported by many of the prominent builders of Southampton and others connected with the trade. It being the first large gathering since the recent arbitration proceedings over the wages and rules question, the opportunity was taken of thanking the architects, builders' merchants, and others who gave evidence at the same. A vote of thanks was also accorded the hon. secretary (Mr. A. T. Doggrell) for his services in making such excellent arrangements for the outing. After lunch the trip was resumed further down the river, and tea was partaken of at the St. George and Dragon, Wargrave, following which the party returned to Reading, from whence they travelled by train to Southampton, which was reached about 10.30, the outing being considered one of the most successful in the history of the association.

* * *

Judging from the condition of employment for operative masons, the building and monumental sections of the granite trade at Aberdeen have improved, not only in the city, but also in some of the country districts. Work has been more easily obtained, and, although some of the jobs were completed, and, consequently, a number of men were paid off, fortunately other openings were soon found, so that on the whole employment has been more plentiful. In the city, trade has improved both in the monumental and building branches, though the building trade is still far below the normal state of affairs. There has also recently been evidence of a slight improvement in the granite trade of the city, though it is still far removed from anything like the activity associated in former times with building masons. Still, with the likelihood of several big jobs coming into the market soon, trade ought to be brisker in the latter part of the year than it has been so far. It is very probable that the new extension to the Royal Infirmary will be commenced before long, and this would go far to improve the prospects for the winter and the following spring, and would provide work during the dull months of the year when employment is difficult to obtain. The Prudential Assurance Company have decided to build new offices in Crown Street, and these buildings, once they are in course of erection, will provide a number of men with employment for some time to come. Another job which is likely to come into the market soon is the contemplated extension of Broadford Works. This, along with the other works already in hand or likely to be soon commenced, would seem to point to a long-looked-forward-to and much-hoped-for improvement in the building trade in the city. With the prospect of plenty of work during the fall of the year, and something to look forward to in the winter, the position of operative masons is brighter, and it is to be hoped that there will be no unnecessary delay in getting these contracts under weigh.

Proposed New Works.

The following new works, with others, were recommended for the consent of the London County Council at a recent meeting, subject to certain specified conditions:—

Erection of buildings on a site abutting upon Cambridge Circus, Minerva Street, Centre Street and Felix Street, Bethnal Green, on the application of Mr. W. E. Wallis, on behalf of the governors of the Peabody Donation Fund.

Erection of an office building on the site of Nos. 36 and 38, Queen Anne's Gate, Westminster, at less than the prescribed distance from the centres of the roadways of Queen Anne's Gate and the street leading from Birdcage Walk to Queen Anne's Gate, and with oriel windows, and a hood and pilasters, on the application of Messrs. E. Runtz and Ford, on behalf of the Anglo-American Oil Company, Ltd.

Erection of a two-storey dwelling house upon the site of a stable building known as No. 39a, Odell Street, Old Kent Road, Camberwell, on the application of Messrs. Field, Sons and Glasier, on behalf of Mr. J. Bibbey.

Formation or laying out of three new streets for carriage traffic on the Crofton Park Estate, out of the south-eastern side of Bexhill Road, Lewisham, so far as relates to an alteration in the gradient of Quarry Hill Road, on the application of Mr. J. W. Webb.

Formation or laying out of a new street for carriage traffic to lead out of the north-western side of Denmark Hill, Norwood, on the application of R. Ellis and Son, on behalf of Mr. R. A. Sanders.

Erection of a water-cooling tower at the premises of the South London Electric Supply Corporation, Limited, Bengeworth Road, Norwood, on the application of Balcke and Co., Ltd., on behalf of the South London Electric Supply Corporation, Limited.

Dwelling-houses to be inhabited by persons of the working-class, and proposed to be erected, not abutting upon a street, on a site on the north-western side of Date Street, Walworth, on the application of Messrs. Cluttons.

Erection of an addition to Imperial Court Buildings, Brompton Road and Basil Street, Kensington, whereby such building will exceed in extent 250,000 cubic feet, on the application of Mr. G. D. Martin.

Rebuilding of Nos. 100, 102, and 104, Falmouth Road, Southwark, on the application of Messrs. Colman and Knight.

Trade and Craft.

Vitreous Tiles and Mosaic.

We have received from Messrs. Chance Brothers, and Co., Ltd., glassworks, near Birmingham, some samples of their vitreous tiles and mosaics, which, being manufactured entirely from glass, are therefore very durable, and in fact practically indestructible. The material is of course thoroughly impervious to moisture, and is not affected by acids. Moreover, being of homogeneous material, they cannot possibly craze. They present an extremely agreeable matt surface, which many people may prefer to the high glaze on ordinary tiling; and another pleasant characteristic is a pleasant diversity of the colouring, each specimen being, as it were, "shot" or mottled with harmonious shades of grey, or green, or brown. The units are made in two forms—with mechanically correct edges for close jointing, and with antique rough-cut edges for fixing with open joints. The units are made in various sizes, and in varying forms for angle tiles, skirtings, mouldings, etc. The mosaics are particularly adapted to the decorative treatment of walls and floors, services for which the material seems to be particularly suitable on account of its hardness and non-porosity, as well as by the brightness and permanency of the colouring. Samples can be had on application.

The Excelsior Flooring Cramp.

A patent flooring cramp which should be a boon to builders has been placed upon the market, a mere glance at which suggests at once the power, simplicity, and efficiency of the implement. Well constructed of steel throughout, it will stand the roughest usage without fear of breaking. There are no screw-threads to get out of order, as the cramp works on the ratchet-and-pawl system. The two back pawls work alternately, and thus prevent all possibility of the ram slipping back. It is described by the vendors as an essentially heavy-service tool, easily able to cramp twenty floor boards at one time, if that number were practicable, and at least capable of dealing at one operation with as many boards as can be laid, the boards being closed evenly throughout their entire length. It is quickly and easily fixed, and the workman, in operating it, stands upright over his work. The confidence of the vendors in the complete efficiency of the "Excelsior" flooring cramp is shown in their willingness to take it back in any instance in which it is not approved of. The vendors are Messrs. Shaw, of Wolverhampton.

Insurance.

Free £500 Accident Insurance Coupons have this week been sent to the following:

N. B. (Wimbledon), H. H. (Workington), G. O. J. (Shrewsbury), J. E. P. (Bath), A. B. (Blackheath), W. B. G. (London), F. C. (Dringhouses), A. S. (Keighley), S. H. (York), J. B. (Shrewsbury), W. J. D. (Plymouth), A. D. (Westgate-on-Sea), A. G. L. (Bristol), W. H. G. (Dover), W. J. S. (Woodbridge), E. F. A. S. (London), R. D. (Stranraer), J. F. G. (Manchester), H. W. A. (Teddington).

For particulars of our Free Insurance Scheme, apply to the Manager, Technical Journals, Ltd., Caxton House, Westminster.

F. HIGGS (LONDON) AND W. THOMAS (CARDIFF)

Representatives on the Employers' Parliamentary Council:
ERNEST J. BROWN (LONDON). WM. SHEPHERD (LONDON).

ADMINISTRATIVE COMMITTEE.

Ex-officio Members:—The President, Vice-Presidents, Hon. Treasurer and Hon. Auditors.

ELECTED MEMBERS.

Northern Centre—T. WILKINSON (Middlesbrough). W. R. THOMPSON (Dewsbury). GEORGE MACFARLANE (Manchester). JAS. STORRS, J.P. (Stalybridge).

Midland Centre—H. WILLCOCK (Wolverhampton). ALBERT S. SMITH (Birmingham).

South-Eastern Centre—WM. SHEPHERD (London). W. F. WALLIS (Maidstone). B. I. GREENWOOD (London). J. BELL, J.P. (Cambridge).

South Western-Centre—Coun. W. N. BLACKBURN (Newport, Mon.). E. J. NEALE (Bristol).

Secretary:
A. G. WHITE, 31 and 32, Bedford Street, Strand, London, W.C.

HALF-YEARLY MEETING AT PORTSMOUTH.

The half-yearly meetings of the National Federation of Building Trades Employers of Great Britain and Ireland were held on Tuesday, July 20th, and Wednesday, July 21st, in the Grand Jury Room of the handsome Town Hall, which had been courteously placed at their disposal by the Mayor and Corporation.

The choice of Portsmouth as the place of meeting was in every respect happy. The Portsmouth Association is one of the most vigorously conducted and flourishing associations in the South, and well deserved the honour implied; and the town, besides being replete with historical interest, and striking, dominantly and persistently, the note of Great Britain's naval supremacy, is by no means destitute of picturesqueness. Portsmouth fascinates by its strongly marked individuality and character, military and nautical; and "Sunny Southsea," which adjoins it, gives a certain degree of relief or relaxation from so much militant strenuousness, affording all the attractions of a delightful holiday resort, and it was here, at the Queen's Hotel, facing the sea, and commanding a magnificent view of the busy Solent and of the wooded undulations of the Isle of Wight that the Federation had its headquarters.

The buildings of Portsmouth naturally received a great deal of attention from the Federation visitors. The Town Hall, where the meetings were held, has been described, without much exaggeration, as a "noble" building. It was built by Messrs. Armitage and Hodgson, of Leeds, to the designs of the late Mr. William Hill, F.R.I.B.A., also of Leeds, and cost more than £140,000. It is of the Corinthian Order, and is built of Portland stone; the portico, supported by six columns, being approached by a magnificent flight of granite steps. The cupola clock tower, rising to a height of 210ft. above the level of the road, is perhaps rather too elaborately decorated, but the fussy detail is lost at the great distances from which the tower can be seen. In the tympanum of the pediment, Britannia is shown surrounded by the figures symbolical of Peace and Plenty, but hardly significant of the genius of the town, which is nothing if not warlike, as the battleships off Spithead, and the grand old "Victory" in the harbour, perhaps sufficiently testify. Inside, occupying the main floor, a vast assembly hall is surrounded by galleries and by wide corridors off which are the various rooms for council committees, etc.; the ground floor being devoted to the municipal offices. The hall is 128ft. by 60ft. by 70ft. from floor to ceiling. There are seats for 2,000, but the hall will hold 3,000 persons. Dominating it is one of the largest organs in the kingdom. This instrument cost £3,500. The work of building occupied nearly four years, and the hall was opened on August 9th, 1890, by the then Prince of Wales, who is now King Edward VII.

Rather too close to the Town Hall—which, however, has an unusually spacious area in front of it, and a park on its north-east side —is the Municipal College, which cost £110,000 to build, covers a total ground space of about 90,000 sq. ft., and has a tower 140ft. high. This building also was built by Messrs. Armitage and Hodgson, of Leeds, the architect being Mr. G. E. Smith, of Southsea. It has a steel-framed roof, floors of steel joists and concrete, and granolithic staircases. It was opened in 1908. There are, of course, many other buildings of interest. There is the usual Carnegie library, and there are some others; and the town is naturally rich in banks and barracks, each after its own kind providing the sinews of war. Passing mention may be made to the sturdy old parish church (Transitional), the Roman Catholic Cathedral with its fine rose window; the George Hotel, which was the last house on English soil in which Nelson slept; the house where, in 1628, the Duke of Buckingham was slain by Felton; and the unpretentious dwelling whose red-tiled roof sheltered the infant head of Charles Dickens, who was born there, as some blatant lettering tells, on February 7th, 1812.

The Council meeting of the Federation, held on Tuesday, July 20th, at 2.30 p.m., was attended by about 34 members, Mr. Ernest J. Brown, President of the National Federation, in the chair. The proceedings, of course, cannot be here published.

The half-yearly general meeting was held in the same room on Wednesday, July 21st, at 10.30 a.m., Mr. Ernest Brown again presiding. In honour of the expected presence of the Mayor, the President wore his chain of office. The Mayor, however, did not arrive in time to give his address of welcome before the business began.

The notice calling the meeting, and the minutes of the last annual meeting, held at the Trocadero, Piccadilly, London, on January 27th, 1909, having been taken as read, the latter, on the motion of Mr. James Wright (Nottingham), honorary treasurer, seconded by Mr. W. Wistance (Walsall), being confirmed, and its circulation authorised.

The next item on the agenda referred to the welcome that the Federation was prepared to offer to Mr. W. R. Poynton, hon. life President of the National Federation of Building Trade Employers in South Africa, who, however, being in this country for the benefit of his health, was forbidden by his medical adviser to undertake the journey from London to Portsmouth. The secretary read a letter to that effect from Mr. Poynton, who, it appeared, had been led to suggest the formation of the South African Federation through having attended one of the congresses of the National [British] Federation held five years ago. The secretary stated that he had had an interview with Mr. Poynton, who had expressed a cordial desire for some form of affiliation, or some bond of union between the two Federations.

He said that in conversation with Mr. Poynton the latter had suggested to make subscription to the official journal a passport to affiliation.

The President said that he was sure the meeting would have extended a most hearty welcome to Mr. Poynton, the cause of whose absence all present greatly regretted; they would all wish him a speedy return to health. It was very gratifying to find that the South African Federation had thought us worthy of imitation. He (the President) saw no objection to the suggestion. In giving it effect, the details might be left to the Administrative Committee.

Mr. Davidson thought that there was a possibility of forming a dangerous precedent.

The President, however, said that the action bound the Federation to nothing beyond a reciprocation of the sympathy and goodwill that had been expressed towards us. It was simply a matter of "hands across the sea."

It was agreed to refer the matter to the Administrative Committee with power to act.

At this point the Mayor of Portsmouth (Councillar J. Biggs, J.P.) arrived. He apologised for being late, explaining that he had mistaken the time of the meeting. In offering the National Federation a very hearty welcome to Portsmouth, he said that this town, like most others, ought to be very grateful to the much-abused speculative builder, to whose courage and enterprise a vast amount of building improvement was due. To this influence he attributed much of the rapid and enormous expansion of Portsmouth, where, within thirty years, remarkable improvements had been accomplished, and there had been an immense increase in the population, which now numbers about 210,000. The Town Hall, and most of the more important buildings, had been put up within the past seventeen years. Since builders had played so important a part in the expansion of Portsmouth, he was glad to offer their acredited representatives a hearty welcome to the town, and to receive them in the Town Hall, a building of which, as builders could readily understand, the people of Portsmouth were very proud.

The President replied in a graceful and humorous speech, in which he made a sly allusion to a stormy scene that had occurred on the previous day at a meeting over which the Mayor had presided, but offered his worship a solemn assurance that the builders, although by no means deficient in the fighting spirit in which Portsmouth seemed to abound, always conducted their deliberations with the utmost seemliness and decorum.

The Mayor having retired, the sixty-second half-yearly report was, on the motion of Mr. James Wright and Mr. Wistance, taken as read. The chief points are here given:—

State of Trade.—No general improvement of the building trade can yet be reported. In some parts is it worse than a year ago.

Conciliation Boards.—The National Board has held two meetings during the past half-year. The cases considered were:—Appeal of carpenters and joiners of Swansea: decision given, "That the wages of Swansea carpenters and joiners remain as at present, and that the hours of labour be those proposed by the operatives' notice." Appeal of the employers of stonemasons of Manchester: No decision on the question at issue, viz., a reduction of wages and alteration of hours, was given by the Board, but the parties were recommended to refer the matter to a Board of Trade arbitrator.

The following amendments to the rules having been duly notified were passed at the annual meeting of the National Board on May 25th, 1909, and are now operative. Rule 2—Lines 20 to 24:—To add the portion underlined to provide for dealing with employers from another town:—"If, however, the principal place of business of the contractor is not situate within the district covered by the local conciliation board, or should a dispute arise on a job of an employer outside his own town or district, then it shall be competent for him to demand, etc., etc. Period for which a decision shall endure: That it shall be the duty of every Board of Conciliation when giving a decision to take into consideration the desirability of stating a minimum period for which such a decision is to endure. Private consultation at board meetings: That should either side desire to retire for private consultation during the sitting of any of the Boards after hearing the evidence, they shall be allowed to do so.

THE TOWN HALL, PORTSMOUTH, WHERE THE NATIONAL FEDERATION MEETING WAS HELD.

Application of builders' labourers for admission to conciliation scheme: The resolutions of the National Federation in regard to the admission of builders' labourers to partial participation in the scheme were considered at the annual meeting of the Board on May 25th, 1909, and accepted, and an intimation has been sent to the builders' labourers that they may participate on these conditions. The resolutions referred to are:—"That this Federation recommend that the application of the builders' labourers for admission as parties to the National Scheme of Conciliation be not acceded to, but that builders' labourers be allowed to join Local Conciliation Boards where the employers and skilled operatives are in favour of such a course, provided that the agreement under which they are so admitted shall clearly state that their admission is purely optional and not of right, and shall further provide that no labourer representatives shall sit on the Centre or National Boards to adjudicate on cases from towns where the labourers' union or unions do not receive recognition, and shall only sit on local boards when matters affecting their interests are concerned." "That where a labourers' union is admitted into the Local Conciliation Board of any district and a dispute arises which the local board cannot settle, a joint application by the parties concerned for their case to be heard by the Centre and National Boards shall be granted, provided both applicants agree to accept the decision of either of these Boards, and to pay all expenses of the hearing or hearings." Suggestions for further amending the rule as to quorum and for a new rule as to notice of alteration of local rules where a case is sub-judice by the Conciliation Boards were approved, and are recommended to the parties to the scheme for further consideration.

The recommendation of the Board to the parties at Southampton to refer the dispute to an arbitrator has been acted upon, and the dispute has been referred to the decision of Mr. A. A. Hudson, of the Board of Trade.

Satisfactory reports as to the working of these Boards have been received from the Midland Centre which says: "The past year has not been quite so free from disputes in the Midland Centre area as in the previous 12 months. Fortunately the difficulties have not been serious, and their settlement had proved conclusively the value of the various Conciliation Boards."

The National reserve fund continues to make satisfactory progress, a considerable amount of arrears have been received, and a further £500 has been invested in India 3½ per cent. stock of the value of £502 19s. 5d.

Third Annual Return of Membership: With a view of collecting statistical information likely to be useful to the Federation generally, the Adminstrative Committee again issued forms requesting a return of the number of members in the respective associations, and also the number of men and apprentices employed in the various trades for a week in June, 1909. The forms have been simplified and so arranged that members may make their returns under a reference number without appending any signature. It is hoped that the greater privacy so secured will induce all members to assist in making these returns as complete as possible.

Fair Wages Clauses in Contracts: Two typical clauses have been drafted to serve as models, and having been approved by the Administrative Committtee, are now available for the use of the membership.

The N.A.O.P. Agreement: The Joint Committee, under the above-named agreement, after careful consideration, has drafted a revised agreement of a more comprehensive character, especially in regard to clause 5, which has been redrafted. A new clause has been added authorising the adoption of regulations governing procedure on similar lines to those adopted by the Conciliation Board. The revised agreement and regulations have been formally approved, and recommended to the parties to the agreement for ratification.

Smithies v. N.A.O.P.: It is reported that the costs in this action are now being taxed, but as yet it is not possible to ascertain what the financial outcome will be.

Prevention of Accidents in the Building Trade: The Building and Engineering Works Bill, a Government measure to amend the Factory Acts, by extending certain provisions thereof to enable scaffolding, etc., regulations to be applied to the building trade, has been re-introduced this session.

Form of Contract: An agreement has been arrived at between the R.I.B.A. and the Builders' Institute as to the terms of the proposed amendment to clause 30, and the consent of this Federation is now desired thereto.

Conditions of Contract and Conditions in Quantities: The attention of the R.I.B.A. and of the Quantity Surveyors' Association has been drawn to what appears to be a growing practice of stating at the beginning of bills of quantities that the conditions of contract will be those agreed between the R.I.B.A. and the Builders' Institute, the while subsequent conditions are inserted in the quantities which vary the said agreed conditions of contract. As those subsequent conditions are probably repeated in the specification, there is danger that a confusion will arise which would make it extremely difficult to say what are the exact terms of the contract between the parties. The Quantity Surveyors' Association in reply say they cannot understand how the inconsistency of which complaint is made can possibly arise when the quantities are prepared by a reliable surveyor. They express themselves quite in accord with us in deprecating such a practice, and will use their influence wherever practicable with a view to effecting its discontinuance. The R.I.B.A. has published the communication in its journal for the information of members.

Checkweighing Bill: The attention of the County Federation has been called to the above Bill, which may affect quarry owners, with a request for any observations they may desire to make thereon.

Comparative Statement of Wages and Hours: Particulars of wages and hours in the federated towns have been collected and published in the "Builders' Journal." It is hoped the new arrangement of the towns by Federations and in groups of over and under 100,000 inhabitants will be found useful to members in negotiating wages agreements, and lead to something like a uniform level of wages in the respective classes for given areas.

Finance Bill: The attention of the County Federations was called to this Bill. The response was very small, and on the matter being brought before the Administrative Committee it was decided not to take any action.

Home Office Departmental Committee on Lead Poisoning: On May 17th a communication was received from the Home Office saying that it was proposed to appoint a Departmental Committee to consider the question of lead poisoning in the painting and plumbing trades. The Federation was requested to communicate with the bodies concerned, and the London Association appointed their President, Mr. F. G. Rice, the National Painters' Association their secretary, Mr. W. G. Sutherland, of Manchester, and after consideration of the names suggested by our County Federations, the President selected Mr. J. W. Bellamy, of Birmingham to represent this Federation. These names with addresses have been duly forwarded to the Home Office. As the operatives concerned will bring forward evidence tending to show the necessity for restrictions and regulations relating to the use of poisonous paints, the employers will have to be prepared with rebutting evidence or their case may suffer, it would be well, therefore, for the County Federations and local associations to be inquiring as to suitable witnesses in readiness.

Government Departments and Tendering Without Quantities: Particulars having been supplied of two cases in which the War Office and the Post Office had called for tenders for jobs of considerable size without supplying quantities, a letter was sent to the heads of those departments calling attention to the cases and requesting that in future quantities should be supplied for works of, say, £500 and upwards. A reply has been received from both departments saying that in future as far as practicable they will supply quantities for works likely to exceed £500.

[References to the action taken with respect to the Trade Disputes Bill, the Trade Boards Bill, and to the Housing and Town Planning Bill, are made in the report, but, having been already dealt with in the journal, are not here repeated.]

Official Journal: Various circulars have been issued by the Journal Committee with the object of eliciting increased support from the membership. Several associations have arranged for every member to receive the journal, and amended the subscription rate to cover it, with entirely satisfactory results, and others are promising to follow suite. This is the true way to make a big success of our official journal, and should be largely imitated.

Annual Conference of Secretaries: Reports of the 1908 Conference have been distributed. The 1909 Conference will be held at Leeds on or about October 20th. The committee is very desirous that every local secretary should be sent by his association to take part in these conferences, which are of great educational value, and have led to very satisfactory developments of organisation in certain localities in consequence of the suggestions and encouragement which those attending have received. It is understood that considerations of expense keep back many from attending, and it is therefore very desirable that the local association councils should take steps to remove any hindrance of this kind.

Protection of Members: The case from York, referred to in last report, has resulted in a withdrawal of claim against our member, and the York Association has thanked the Federation for the assistance rendered.

Court of Arbitration. As a result of the communication sent to the President of the Board of Trade through the Employers' Parliamentary Council, as mentioned in last report, the following reply has been elicited:—"The Board of Trade have endeavoured to obtain the services of well-known and representative employers, and at present not those of representatives of particular industries. The Board considers that these representative employers would fully appreciate the interests of the employers' side in any dispute, and in cases in which they are not familiar with the technical details of the industry affected, they have power to appoint technical advisers to advise them. Should, however, the parties to a dispute request the Board to appoint a court including employers and workpeople from their own industry, the Board would give the request their most favourable consideration."

Priced Schedules with Tenders: As a result of inquiries addressed to the various branches of the Federation as to the extent of the practice of demanding priced schedules with tenders, it appears to be generally confined to engineers or other officials representing certain railway companies and public bodies; there appears, however, to be a tendency for architects to imitate them in some places, and it seems desirable that some general policy should be decided upon and adopted by the Federation in regard to this question.

The Proposed International Federation for the Building Trade: In accordance with instructions of the Committee, the secretary attended a meeting in Brussels of the Committee charged with drawing up a constitution for the proposed Federation. Delegates also attended from Belgium, Holland, Italy, Hungary, and France. The secretary secured the assent of the Committee on two points which appear to be of primary importance for the success of the contemplated Federation; one, that the annual subscription should be fixed for the present at 10 centimes (or approximately 1d.) per member, the second, that in future International Congresses other languages than French should also be recognised and interpreters provided so that delegates might address the congress in one of the four principal European languages. For the Executive Council, however, French would still be used.

Belgian Builders' League: On April 24th and 25th, the above League celebrated the 25th anniversary of its foundation, and as the event coincided with the meeting of the Committee just referred to, its members were invited to assist at the celebration.

The employers at Colwyn Bay are endeavouring to form an association, and every assistance will be offered them. Several other Lancashire towns have received attention by the organisers, including St. Helens and Wallasey, but there is nothing further of a definite nature to report at present. The Committee regret to state, however, that owing to the state of trade, and no doubt other reasons, great apathy is shown in the smaller towns with regard to organisation, and the difficulties in the way of extending the membership are very great indeed. A conference of secretaries of the district was held on January 22nd last, with satisfactory results; it has been decided to hold such meetings half-yearly in future.

With regard to the paragraphs in the report dealing with the application of labourers for admission to the conciliation scheme, a remark by Mr. Davidson as to the attitude of the Yorkshire associations on this question gave rise to a short conversation, which the secretary summed up with a remark to the effect that it is advisable for local associations to accord this privilege only where rules exist and have been agreed upon between themselves and the labourers.

National Form of Contract.

On the motion of Mr. F. L. Dove, L.C.C. (London), seconded by Mr. F. Higgs (London), it was agreed to assent to the following amendment of clause 30 of the National Form of Contract:—

PRESENT WORDING.	AMENDED WORDING.
"No certificate of the Architect shall be considered evidence as to the sufficiency of any work or materials to which it relates, nor shall it relieve the Contractor from his liability to make good all defects as provided by this agreement."	"No certificate of the Architect shall of itself be considered conclusive evidence as to the sufficiency of any work or materials to which it relates so as to relieve the Contractor from his liability to execute the works in all respects in accordance with the terms and upon and subject to the conditions of this agreement or from his liability to make good all defects as provided thereby."

In discussing this proposal, to which the legal advisers of the R.I.B.A., and the Builders' Institute had agreed, and to which the assent of the National Federation was sought by the Builders' Institute, Mr. W. H. Hope (Sunderland) said he had no doubt that the amendment had been suggested in consequence of a decision that had been given by Lord Justice Farwell. Mr. Hope thought the alteration superfluous, because the decision on appeal showed that as a matter of fact, there is no item in a contract, or dispute that can arise with respect to it, that cannot be taken to arbitration. On the other hand, the alteration might possibly turn out to be troublesome, as circumstances might conceivably arise in which it might be necessary to go to court in order to determine the meaning of the clause. However, he would make no motion on the subject.

The Official Journal.

Mr. George Macfarlane (Manchester), hon. vice-president, moved the following recommendation of the Administrative Committee:—"That it be a recommendation to local associations that every member be supplied with a copy of the journal, and that the cost thereof be added to his subscription on the lines adopted at Sunderland, viz., 5s. additional subscription payable by each member, and the balance of cost paid out of the funds of the local association." Mr. Macfarlane said there could be no question that the official organ of the Federation ought to be received and read by every member of every association, and he was glad to know that certain associations had already adopted the sensible practice of buying the journal wholesale and distributing the copies among their members. He pointed out that the journal was now giving Federation news in every issue, instead of only once a month as heretofore, and he urged secretaries to avail themselves as freely as possible of the improved facilities.

Mr. A. S. Smith (Birmingham) thought that association secretaries might do much to assist in making the journal useful and interesting to members.

The President urged secretaries to preach the gospel of the "Builders' Journal" as a strong power in the land, the accredited organ of a large and an influential organisation. In particular he advised all associations to adopt the very sensible course that had been already put into practice by many of printing on their stationery and note headings a line announcing that the "Builders' Journal" is the official organ of the National Federation.

Mr. F. W. Amphlet (Birmingham) observed that the suggestion as to mentioning the journal on association note-headings had been willingly adopted in the Midlands.

Mr. Percy Hastings, invited by the President to address the meeting, said that there were a few secretaries who as yet did not seem quite fully aware of the tremendous power that the journal can be to them if they make proper use of it. He had no desire to boast, but he could not help being aware that there were certain respects in which the journal was unequalled by any organ in the trade Press. He concluded by offering some practical advice as to ways in which secretaries could more fully avail themselves of the immense advantages accruing from the support of a powerful and up-to-date trade organ such as the "Builders' Journal."

Mr. Hasting's remarks were very cordially received, and it was unanimously resolved to adopt the report and to recommend it to the careful consideration of County Federations and local associations.

Revised N.A.O.P. Agreement.

This matter was also considered, and will be dealt with in a future issue of the Journal.

Priced Schedules with Quantities.

Mr. James Wright introduced a recommendation by the Administrative Committee that, as amended in the course of the debate, reads as follows: "That each Federation and local association should, as a matter of principle, instruct their members to refrain from sending in priced schedules with tenders, but if not able to avoid doing so should endeavour to arrange locally with engineers, surveyors, and architects, who at present insist upon having priced schedules with tenders, that such schedules should be delivered under seal, and that the schedule of the accepted tender only should be opened, and the others returned to the unsuccessful contractors." Mr. Wright stated that inquiries by the secretary as to the extent to which the practice prevailed of insisting on priced schedules showed that railways, corporations, and architects, acting under education committees, appeared to be increasingly addicted to it; and he hoped that, since most builders found it objectionable, every effort would be made to break it down.

Mr. Stirling, in supporting the resolution, said that although the matter had been before the Federation for a good many years, the bad practice was apparently increasing. He suggested that better progress might be made if the Institute of Civil Engineers and the R.I.B.A. were approached on the subject.

Mr. Easten thought that each Federation and local association should, as a matter of principle, request members to refrain from tendering under such conditions.

Mr. Davidson thought that it should be emphatically recorded that the Federation wishes to abolish this bad custom.

The resolution was recommended to the county Federations and local associations for consideration and adoption as far as practicable.

Proposed Builders' Bureau.

A proposal to appoint a provisional advisory committee of builders to co-operate with certain Bureau officials with a view to the organisation of a builders' bureau was introduced by Mr. Smethurst. In the ensuing discussion, in whch Mr. J. W. White, Mr. Stirling, and Mr. Blackburn took part, the prevailing opinion was expressed that any such organisations (of which the utility was doubted) should be entirely in the hands of the builders themselves, and the resolution was lost.

Next Annual Meeting.

It was decided that the next half-yearly meeting should be held in London.

Festivities.

At the conclusion of the business, the members of the Federation were entertained at luncheon by the Portsmouth and District Master Builders' and Building Trades Association (President, Mr. G. J. Davis; vice-presidents, Messrs. J. Harding, and A. E. Porter, T.C.; treasurer, Mr. James Cockerell; secretary, Mr. Frank B. Roskell). The toast-list was as follows:—"The King and Royal Family," proposed by the President (Mr. G. J. Davis); "The Mayor and Corporation," proposed by Mr. S. Smethurst, senior, vice-president of the National Federation, response by the Mayor (Councillor J. Baggs, J.P.); "The National Federation of Building Trade Employers," proposed by Mr. J. W. Perkins, T.C., response by Mr. Ernest J. Brown; "Portsmouth and District Master Builders' and Building Trades' Association," proposed by Mr. E. J. Brown, response by Mr. G. J. Davis.

After the luncheon, members were conveyed to the Dockyard, where (by special permission of the Commander-in-Chief), they were shown over the Vernon Torpedo Depot.

The weather throughout the meeting remained consistently fine, and all the conditions (except perhaps the firing of ordnance in the dead of night), combined to render the Federation's Portsmouth visit very pleasantly memorable.

General Federation News.

OLDHAM AND DISTRICT ASSOCIATION.
Secretaries: Cowper and Dean.

The half-yearly general meeting of Oldham and District Master Builders' Association was held at the Cafe Monico, Union Street, Oldham, on Friday evening, July 9th, Mr. S. Smethurst (president) in the chair.

The report for the half-year ending June 30th, 1909, was approved and adopted.

Arising out of the report, Mr. Heywood asked the amount of fine imposed in the case of the breach of inter-trading rule particularly referred to in the report, and on being informed that the amount was £3 3s., suggested that the expression "heavily fined" was misleading, and in proportion to the amount of the work involved was very small. It was pointed out that the expression was used because the fine was heavier than had been previously enforced in any case.

The secretary having explained that rule 6 provided for only four vice-presidents, while at present there were five, it was resolved that the rule be altered so as to provide for the election of six vice-presidents.

The question of there being no arbitration clause in the fair contracts clause adopted by the Oldham Corporation was fully discussed, and it was resolved that a letter be sent to the town clerk stating that the members in general meeting consider that at least a provision should be made that in the event of the Corporation deciding to impose a penalty or cancel a contract under the clause, the contractor should have the right to appeal against the decision to an independent arbitrator. It was further decided to leave the matter in the hands of the Executive Committee.

The question of arbitrary conditions which had been inserted in bills of quantities and contracts during the six months was then considered. The secretary reported that several complaints as to these arbitrary conditions had come to hand from members, and more particularly with regard to prolonged maintenance clauses. After discussion, it was resolved that the Executive Committee be asked to deal further with the matter, and call the attention of architects to the growing practice of inserting these arbitrary conditions in bills of quantities as well as in contracts.

The question of the long delay in squaring up and closing jobs by architects was brought forward by Mr. Butterworth, and after a long discussion the President pointed out that the best way of dealing with these matters was to make it compulsory upon members to sign only the form of contract approved by the R.I.B.A., Institute of Builders, and National Federation, and it was a question of altering the present rule 16a, making the use of the forms referred to compulsory instead of voluntary. Mr. Rose promised to give notice of motion for alteration of rule 16a at the annual general meeting, and in the meantime it was resolved that the Executive Committee take up this question with the architects.

The question of direct tendering was also brought forward by Mr. Horrobin; but as the President stated that the hour was late to commence discussing this big question, it was decided to bring same forward at the next general meeting, and also in committee.

The question of fixing a probationary period during which firms or individuals should be in business as employers before becoming full members of the association was then brought forward by Mr. Rose and Mr. Brooks, and after some discussion it was pointed out that notice of motion for alteration of rule 3 should be given before this could be dealt with, so as to give all members a full opportunity of considering the

matter before dealing with same. The president promised that it should have the consideration of the Executive Committee in the meantime.

Oldham and District Association's Half-Yearly Report.

In the report for the half-year ending June 30th, it is stated that six new members have been secured during the half-year, and none have been struck off the books. The number of members now on the books is 187. The association is, therefore, one of the largest connected with the L.C. and N.W. Federation. Financially, everything is in a satisfactory condition, and the local reserve fund has been increased. The entrance fee is now increased to £2 2s. Members who have paid their subscriptions to date are supplied with a Federation Year Book, containing list of members and local employers' and operatives' rules, together with the Federation report, and other valuable information.

During the half-year the employers' representatives in the joiners' branch have dealt with the question of reduction in wages of the operative joiners from 9½d. per hour to 9d. The demand was refused by the operatives, and the matter has been dealt with at two sittings of the Local Conciliation Board, but on being voted on by ballot resulted in equal voting, and the case was then referred to the Northern Centre Conciliation Board. The representatives attended with the case before the Board at Leeds, and, after going fully into the evidence, the voting resulted again in a tie, and no decision could be given. The employers are now considering the question of appealing to the National Conciliation Board, to be held in London. All immediately surrounding districts are paying less wages than in Oldham. In dealing with this case numerous meetings referred to below were held, and the ramifications of the Builders' Associations and Federations have been realized by the operatives, and appreciated by the employers, and the Local and Centre Conciliation Boards have served a useful purpose in such dispute.

The Executive Committee have dealt with several architects and proprietors regarding inviting tenders from members in competition without supplying quantities in contravention of the rule on the subject. A special circular has just been sent out to all members, requesting unqualified adherence to the rule. The matter will be brought before the members for discussion.

A sub-committee was appointed some time ago to deal with the suggested new Fair Contracts' Clause and the proposed new Improvement Bill, and deputations have appeared on two occasions before the Finance Committee of the Oldham Corporation regarding the matter. Much correspondence has ensued, and the committee have endeavoured to carry out the instructions of the members to resist the new clauses to the full extent. The result has been the removal of objectionable features in two or three clauses, but the maximum penalty of £500 remains, and without arbitration clause, the Corporation having sole right to fix a penalty for an alleged breach of the clauses. The committee have decided to ask the Corporation to consider the question of providing for an appeal against an adverse decision.

The intertrading rule has attained the desired object of increasing the membership to such an extent that the effect is not felt to be any hardship, and firms, who, in the event of a strike or lock-out through being outside the Association, might have proved a stumbling block to an effective settlement, now appreciate and obtain the advantage of the intertrading rule, and are prepared to work harmoniously along with old members. As all the principal firms in the building trade are now members of this association, intertrading can be carried on without difficulty. The National Federation recommend all associations to adopt this rule, and full reasons for its adoption can be supplied on application.

It has already been reported that the National Federation are endeavouring to raise £10,000 as a reserve fund by voluntary contributions, and have allocated the collection of certain amounts to the various centres and County Federations. The L.C. and N.W. Federation have decided to raise a reserve fund of £3,000 of their own first, and have also decided to contribute £1,600 in four yearly instalments towards the "National Fund" out of same, if possible. Your committee some three years ago decided to ask for support from members towards the L.C. and N.W. Fund by raising a minimum sum of £300 in Oldham, subject to a proportion being handed over to the "National Fund." The subscriptions by local members to date amount to £286, and there are further promises of £4 11s. 6d. still outstanding, but only a small proportion of members have yet subscribed. Only £14 is now wanted to make up the amount required, and Oldham will then have contributed liberally to the fund, in proportion to its strength and position.

Attention is called to the growing popularity of THE BUILDERS' JOURNAL as the official organ of the National Federation, and to the fact that it contains every week reports of the most important transactions of the various Federations and Associations.

The attention of members is again called to the fact that next year the Association attains its majority.

Midland Centre.

The half-yearly meetings of the Midland Centre were held at the Dartmouth Hotel, West Bromwich, on Thursday, July 15th. The Executive Council met in the morning, and were subsequently entertained at lunch by the president and members of the West Bromwich M.B.A.

At the meeting of members in the afternoon, the President (Councillor H. Smith) took the chair, and there was a fair and representative attendance.

The secretary was instructed to attend the half-yearly meeting of the National Federation at Portsmouth the following week.

The Secretary reported that, as a result of inquiries, it did not appear that the practice of asking for priced quantities with tenders existed to any large extent in the Midlands. The exceptions were the Derby County Education Committee, H.M. Office of Works, and the railway companies. The meeting approved the resolution on this matter to be submitted at the National Federation meeting.

The half-yearly report stated that the building industry still remains in a depressed condition. There had been no serious labour troubles in the centre during the past six months. Two disputes (at Birmingham and West Bromwich) had been settled by the Midland Conciliation Board. Cash in hand on account of Midland Centre Reserve Fund, £55 13s.; National Reserve Fund, £26 11s. Mr. F. H. Fish had been appointed on the National Council, in place of Mr. J. Wright, who was now an *ex-officio* member. Reference was made to the third conference of the Midland Centre secretaries, and to the annual meeting of the Midland Centre Conciliation Board. The Council believed that the successful working of the Board had been largely due to the ability and interest which the retiring chairman (Mr. J. B. Whitehouse) had devoted to the office. The Collective Insurance Scheme with the Law, Car and General Insurance Corporation, Ltd., had been renewed for another twelve months on the same terms and conditions as last year. Reference was made to the comparative statement of hours and wages in THE BUILDERS' JOURNAL, and the local secretaries were requested to cooperate in making the statement as full and accurate as possible. All arrears of subscription for last year were now paid, with the exception of one item. Although few subscriptions had been paid for this year, the balance in hand was £48 9s. 2d.

The report and financial statement were approved and adopted.

The revised agreement with the N.A.O.P. was approved.

A letter was read from the Mayor of West Bromwich (Councillor Joseph Lawley) ex-

pressing his regret that he had been unable to meet the Executive Council at lunch or the members at the tea which was provided at the close of the meeting.—F. W. Amphlet, Secretary.

BURTON-ON-TRENT ASSOCIATION.

Secretary: A. W. Chamberlain.

A general meeting of the Burton-on-Trent and District Building Trade Employers' Association was held at the Station Hotel, on Wednesday, July 14th, Alderman J. E. Lowe, J.P., in the chair.

The secretary was instructed to attend the half-yearly meeting of the Midland Centre at West Bromwich, and the National Conference of Secretaries at Leeds in October. The Secretary reported that there was still a considerable number of members who had not sent in their employment returns, and it was resolved that a further appeal be made to them to do so.

The fair wages clauses, as submitted by the National Federation, were considered, and the Secretary was instructed to bring same up for further discussion.

The draft agreement of the N.A.O.P. was considered, and it was resolved that the Secretary bring same before the local master plasterers and report.

Burton-on-Trent Conciliation Board.

The annual meeting of the Burton-on-Trent Building Trades' Conciliation Board was held at the Station Hotel on Wednesday, July 14th, 1909. There were present on behalf of the employers: Alderman T. E. Lowe, J.P., in the chair; Councillor Kennard; and Messrs. H. B. E. Edwards, I. M. Harlow, Wm. Wood, G. Cavigan, and A. W. Chamberlain, secretary. On behalf of the operatives, Mr. Jos. Dent, and G. Brimley. The following gentlemen were appointed officers for the ensuing year: Chairman, Alderman T. E. Lowe, J.P.; vice-chairman, Mr. Joseph Dent; employers' secretary, Mr. A. W. Chamberlain; operatives' secretary, Mr. Geo. Brimley.

Alderman Lowe (chairman) remarked that the Board were exceedingly sorry to hear that the late operatives' secretary, Mr. Fred Jones, was retiring from the Board. He (the chairman) had known Mr. Jones from his own first experience of conciliation work, and had always found him to be very just in all his dealings. Alderman Lowe took this opportunity of proposing that a very hearty vote of thanks be accorded to Mr. Jones for the very useful work he has done in connection with this Board. The resolution was seconded by Mr. Chamberlain (joint secretary), supported by Mr. Dent, the vice-chairman, and on being put to the meeting was carried with acclammation.

The usual yearly balance-sheet was passed as read.—A. W. Chamberlain, employers' secretary.

BRISTOL ASSOCIATION.

Secretary: A. J. Pitt.

A meeting was held recently between representatives of the Bristol Association and of the operative societies, for the purpose of forming a local conciliation board under the national conciliation rules, and supplementary to the conciliation rule contained in the local working rules.

Mr. Frank N. Cowlin (President of the Association), was elected chairman of the board, and in taking the chair said it was very gratifying, not only to himself, but to the members of the association generally, to look back upon the amicable relationship which had existed for so many years past between masters and men. He trusted that that record would continue unbroken for many years to come.

Ald. J. Curle, J.P., was elected vice-chairman, and Mr. A. J. Pitt and Mr. G. H. Voisey were elected joint secretaries, representing the employers and the operatives respectively.

The question of stating a time when tendering for work in competition has lately occupied the attention of the Association, and received consideration at the recent monthly meeting.

The Bristol Association have a rule that, except under special circumstances, members shall not state a time when tendering for work in competition, and considerable discussion has taken place as to the advisability of abandoning the rule. Enquiries proved that Bristol apparently stands alone as regards this rule, but several members contended that it was quite enough to meet in competition in respect to price, without an additional competition on time, and this view was supported by a majority of the meeting, and it was decided to allow the rule to stand as at present. It was pointed out that the obvious way out of the difficulty would be for the architect, when calling for tenders, to state the time in which the work must be completed, and a suggestion was made that it would be well to arrange, if possible, a conference with the architects at which this, and other points of interest, might be advantageously discussed. The matter was left in the hands of the President to deal with as he considered best.

The President submitted to the meeting a schedule received from the Bristol Chamber of Commerce in reference to the possibility of increased traffic in building materials between Bristol and the Midlands, in the event of increased facilities being obtained in the canal system between those districts, and upon which question a Royal Commission was now engaged. He pointed out the very great advantages to Bristol trade which would result from direct and rapid water communication to the Midlands, and also showed that such facilities would undoubtedly effect a considerable saving in carriage on tiles, sanitary ware, ironwork, and other building materials which came from that district; and upon his proposition it was decided to fill in the return as to the probable amount of traffic which members would bring over the route, and to support the efforts of the Chamber of Commerce in the compilation and submission to the Royal Commission of a complete and satisfactory statement of the existing traffic, and an estimate of the possible prospective increase which would be likely to arise out of improved conditions and facilities.

Mr. E. J. Neale desired that members not already subscribers to the "Builders' Journal" should be circularised, drawing their attention to the publication and the desirability of giving it hearty support.

Mr. Neale also gave a very interesting resumé of the business transacted at the recent meeting of the Federation in London, dealing particularly with those matters which had received consideration by the local association from time to time.

It was resolved that the annual summer excursion of the Association should this year be still another trip to the river Thames, visiting Henley and Cookham, thus joining up the two portions of the river already visited. Details were left in the hands of a sub-committee.

LEEDS ASSOCIATION.

Secretary: J. Davidson.

The monthly meeting of the Leeds Association was held on July 13th, Mr. Irwin (president) in the chair. It was decided to send to the press a copy of the letter forwarded to the town clerk of Leeds with respect to back-to-back houses.

In regard to the request which has been made to the Leeds Education Committee to inspect the tenders for school repairs which were recently accepted, a letter was read from the secretary to the committee stating that the tenders were confidential communications, and the committee could not see their way to grant facilities for inspection.

Messrs. J. H. Tomlinson and G. W. Wilson were appointed to represent the association at the National half-yearly meetings at Portsmouth.

The draft sub-contract form referred to the associations for consideration by the Yorkshire Federation was carefully considered. Attention was drawn to several features which it was thought needed amendment, and it was decided to leave the further consideration of the form until the next meeting.

"We have an excellent opening which I should like to offer you as one of our own men. The only question is: Do you possess the necessary technical training?"

What answer could YOU make if you were approached by your employer as shown in the picture above?

A man cannot fairly complain of not securing advancement if he fails to prepare himself to take advantage of his opportunities.

Determine *to-day* to get the training which will enable you to embrace every opportunity—to succeed in a high grade position—to command a good salary.

You can readily get this training—without interfering with your present work, without the inconvenience of attending classes, and without embarrassing yourself financially, through the International Correspondence Schools, which exist for the one purpose of preparing ambitious men, by home correspondence study, for better posts.

Leading employers recommend our courses as of definite money value, and our students are continually reporting how their studies have marked them out for promotion. Here is just one instance:—

> "Barrow-in-Furness.
>
> Referring to my progress, I may say that my employer seemed to take a great interest in the Schools and often came to enquire how I was proceeding with my studies, and when you wrote to him of my progress in your School of Mechanical Engineering he came straight to me and congratulated me. Of course, that made me try all the harder, and it certainly has done a great deal towards my getting transferred to a higher standard of work; it is considered a great honour here to be put where I am before five years are up. The report that you sent Mr. .... was instrumental in securing me the better position. (Signed) Wilfred J. Holman."

"OUR STUDENTS' AID DEPARTMENT"

which is in close touch with employers in every district, devotes its entire attention to assisting I.C.S. students in the matter of employment by recommendations to present employers (when desired), information as to vacancies, introductions, etc.

Don't condemn yourself to poor pay all your life. Mark the coupon, or write us about any special career, and ask about our "Students' Aid Department"—NOW.

Practical Notes for Architectural Draughtsmen.

By ALFRED W. S. CROSS, M.A., F.R.I.B.A.,
and ALAN E. MUNBY, M.A., A.R.I.B.A.

Complete Set (27 Large Plates in a Portfolio), 12s.

POST FREE, 12s. 6d.

Prof. C. H. REILLY, of Liverpool University, says: "I think it is a very valuable book, and I hope it will find its way into most architectural offices."

THE "PRACTICAL NOTES" gives in most convenient form for use on the drawing board examples with concise rules, explanations and dimensions for preparing Designs, Perspectives and Working Drawings for Classical Architecture with rapidity and precision.

STUDENTS preparing for the examinations of the R.I.B.A. can learn how to draw The Orders correctly with the smallest possible amount of study and work by utilising the invaluable drawings and data given in this publication.

We shall be pleased to forward a copy of this work on approval to any of our subscribers.

London as it never will be. The concluding number of "London Town—Past and Present" (a publication that has been ably and entertainingly written by Mr. W. W. Hutchings, and has been published in fortnightly parts during the past twelve months), contains an imaginative and speculative contribution on the future of London, by Mr. Ford Madox Hueffer. The article consists of nine chapters and extends over seventeen pages, in which are propounded many interesting theories that the man who knows London, either from force of circumstances or from choice, may profitably peruse. Mr. Hueffer realises that between probabilities and ideals there is a wide difference, and therefore he bases his potentialities upon present-day actualities. He traces from their source the many developments that have all contributed to make London what it is to-day. He passes in review the many catastrophies that have overtaken London, and he marvels that it still survives. He contemplates the Great Fire, and calls it "one of its crowning mercies." In fact London has endured innumerable hardships; has suffered under the ravages of plague; has known what it is to nurse a holocaust in its bosom—and yet it emerges triumphant, and stands to-day as one of the most wonderful triumphs of the resourceful and unfailing ingenuity of man. Mr. Hueffer passes on to the present day and advances some curious explanations of the eccentricities of the London cabman. To him it has always been a matter for some speculation and thought why the cabby invariably pursues a beaten track of bewildering by-ways, in preference to driving by the more spacious and direct routes. One theory, communicated to him by the son of an old cabman, was that "it was along of they sedan-chairs that they cabbies took the roads they did." Another ingenious explanation was that the roads ran where a river had once run; and horses went better where watercourses had been. Later Mr. Hueffer allows full play to his imagination, and gives us an extraordinary picture of his Utopia. He contends that "the problems of a city's life depend on means of communication." He would therefore build four or five railroads radiating from Trafalgar Square, and would equip them with the speediest possible trains. "Along the railways I would set motor-ways, and, between hedges, moving platforms for pedestrians and those who needed exercise. I would clean out the Thames and set upon it huge, swift and fine express launches." Further, Mr. Hueffer believes that the organisation of expeditious railroads that could whisk one from Alresford to London in the same time that it now takes to get from Hammersmith, would have the inevitable effect of making London less a residential city and more a place chiefly for the transaction of business and for amusement. He would abolish all steam and horse-drawn vehicles, and all noxious petrol-driven engines in favour of noiseless and odourless electricity. He fully believes that the Londoner has only to realise the important advantages to be gained by his suggested course and the transformation will be accomplished. Mr. Hueffer takes a "Bakerloo" map of London and traces its sinuous and eccentric movements. It starts from the Elephant and Castle because this is the point where a number of old roads meet. The line hopes eventually to get to Harrow. Does it go straight there? Glance at the map and see, "From the Elephant and Castle it deflects to meet a road coming from an old bridge—the tyranny of a remote Past. It deflects again to come up near an old railway terminus—tyranny of a later Past. It waves round again to hit another railway terminus, again to meet another road centre" and so on. Mr. Hueffer rightly characterises these extraordinary turns and twists as directly the result of tyrannies of the Past. A little later Mr. Hueffer makes surely an unwise statement, which at once classes him with a recent lecturer whose taste in architecture is beyond question, Gothic. "I shall hate to think of the City's knocking down the Mansion House or the Church's pulling down St. Paul's Cathedral. Yet my reason and my tastes alike tell me that the Mansion House is an ugly, clumsy and grimy block, and St. Paul's Cathedral an ostentatious, vulgar and unnational as well as an un-christian imitation." Mr. Hueffer redeems to some extent this somewhat harsh criticism a little later by adding, "But still, figuratively speaking, I would lay down my life before a grimy stone of one or the other was touched," although it is rather disappointing to learn that Mr. Hueffer's momentary burst of patriotism is due only to the fact that "the one is 'characteristic' and the other was built by Wren, has stood for a quarter of a thousand years and contains the bones of Nelson." Mr. Hueffer would make many drastic alterations in his London of the future. He would spare St. Paul's and the Mansion House, but he would pull down all the houses between Westminster Abbey and the Bank of England, "And there along Thames side would rise up the Abbey, the Houses of Parliament, Whitehall Banqueting Chamber (and none of the Government offices, the Scotland Yards, the stucco clubs, hotels, railway stations, and other tawdrinesses of the Victorian era). But there would be the great plain, with, on the north side the National Gallery, St. Martin's Church—and nothing till the eye lit on the Savoy Chapel, Somerset House, the two churches at the bottom of Kingsway, the better parts of the Temple, possibly the Law Courts; Temple Bar brought back, all the Strand and Fleet Street gone, a rise crowned by St. Paul's, the old city churches, the Guildhall, and then the Mansion House. Would it not be a vision of pinnacles and grey buildings? I like to revel in the dream and to dwell upon it whilst my fingers itch to begin some of the pulling down." All these and a great many more alterations of a like character Mr. Hueffer would make in order to transform London into an ideal city. Mr. Hueffer holds up Germany as an example worthy of imitation from the point of view of town-planning; and he is no great admirer of our own garden cities. He would like to stick, as it were, the point of a gigantic compass with a radius of sixty miles into the heart of London, and with it to describe a great circle. All the towns, villages, and hamlets included in this space he would call London. All the pseudo-rustic retreats, all the week-end cottages, all the garden cities and suburban villas should be razed; and in their place should be reared a city of "tall, white buildings. . . . for the transaction of business; there would be huge open spaces flagged with stone, from which would rise the memorial buildings—pinnacled, domed and august—" and this should be called London. It is a wonderful dream; but it represents, nevertheless, a picture of London as it never will be.

Whitgift Hospital Again. Mr. Ford Madox Hueffer is not the only person whose "fingers itch to begin some of the pulling down" of existing buildings; but, there is this difference between him and the others, that they would probably pull down what he would leave up, and vice-versa. The Croydon Councillors want to pull down the Whitgift Hospital; and one would not embark on the wearisome business of opposing the demolition of one of the very few buildings of any artistic value in the whole borough were it not that the Whitgift Hospital is a unique building, and justly famed for architectural, artistic and sentimental reasons. This is not the first or the second time that the building has been threatened, but the tocsin must be sounded to all the opposing bodies and to all who have any claim to artistic feeling to marshal forces for the defence of the old buildings. The reasons for destruction previously advanced have always been utilitarian: the narrowness of the streets, the delay to traffic; the number of accidents occurring, the congestion of the tramways and so on. These were weighty reasons and demanded remedies which the opponents of destruction were not slow to point out. But the philistinism which always lurked behind the ostensible reasons is no longer to be hidden. Indeed the "Croydon Chronicle" of July 24th gives full cry to it, and the utterance is so remarkable that we take leave to reproduce it. "But, perhaps, one of the chief arguments in favour of the removal of the hospital is that based upon architectural grounds. Comparing it with some of the fine stately buildings erected close by in High-street, George-street, and North End, no one with the most elementary ideas of architecture, could possibly say that the Whitgift Hospital is an imposing structure. Its style is altogether out of harmony with the surroundings. Looked at from the outside it is certainly not ornamental, and, contrasting the whole corner with that opposite, it is more or less an eyesore, for it is somewhat deadening and depressing. Only the removal of the hospital, the widening of the roadway, and the erection of a building of more pretentious design could give that corner the imposing appearance that it ought to possess." That the Whitgift Hospital should be made the scapegoat for the bad building around it is a wholly new line of argument. It suffices that as an example of dignity and proportion it so puts its surroundings to shame that its existence as a silent monitor can no longer be tolerated. We will join issue with our contemporary. "No one with the most elementary ideas of architecture," it says, "could say that the Whitgift Hospital is an imposing structure." Well, we do; and we claim to have more than elementary ideas of architecture; and to know the minds of those whose right to speak upon architecture is unquestionable. If the Borough of Croydon chooses to destroy one of the few—the very few—works of art that it possesses, it must do so, though fortunately the proposal must pass the scrutiny of Parliament. We defend the Whitgift Hospital on no ground of archæological or sentimental interest. It is a fine piece of architecture, and a work of art. And those who value our fast diminishing stock of fine old buildings would do well to press upon Parliament the urgency for drawing up a list of our remaining national monuments that the country may not be bankrupted of its architectural treasures at the hands of those who never know nor care for them. Meanwhile the destroyers at Croydon would do well to keep to their utilitarian reasons. It is safer.

Architectural Education. The illustrations on following pages, which give some indication of the work at the Liverpool University School of Architecture, are one more proof that the present forward movement in architectural education is not only a very sound one, but is already productive of good results. For not merely is the work meritorious; but it indicates that our professors and masters are returning to the pot-hooks of architecture, or in other words are inculcating a sound knowledge of the Orders as the basis of the architectural curriculum. It has been the fashion of recent years to sneer at the orders, to view them in much the same light as the study of dead languages is regarded by a certain section of our militant educationists. We are inclined to grant that the study of Greek or Latin is not necessarily essential to the man whose future career will be devoted to commercial pursuits; that in the multitude of things that may be learnt it is necessary and desirable to sacrifice the old tongues for the modern languages. But this merely emphasises the essential differences that divide art and commerce in the matter of education. The basis of commerce change and vary with the expansion of the world's trade and the world's progress. The basis of architecture are fundamental and never alter. One may give new expression to them but one cannot change their character It is the somewhat restless activity of the moderns to find a new expression that has led to the passing fashion of decrying the Orders as so much unnecessary baggage that hampers the student in his progress. The passion for short cuts to knowledge chafes at the delay which the study of the Orders imposes. It desires to be up and doing; it believes that to attempt something, and to keep on attempting something, is a better way of learning than to laboriously study first how the thing should be done before setting about it. The result is that the student, without a proper grasp of the principles that govern his work, starts to design without the most essential qualification. He will be dragooned into some semblance of respectability so far as the common run of buildings is concerned, but he will do things not because he has reasoned them out; but because it is the usual way of doing them or because he has been told to do them in that way. His knowledge will be that of the parrot, not the thinker. And directly he is faced with an original problem he will go to pieces because there is no precedent for him to fall back on, and his brain has never been trained to devise a solution. The same fate has befallen the short cuts to knowledge in other branches of education. The new improved methods for spelling and arithmetic used in our elementary schools only results in the children being worse spellers and calculators than their fathers, and the grotesque mistakes made are standing evidences of the futility of the methods followed. There is no royal road to learning, no backdoor to the inner recesses of the temple of knowledge. The great value of the Orders has ever been to inculcate a sense of proportion, the absence of which is the most conspicuous defect in the architecture of to-day.

OUR ROYAL ACADEMY ELECTION.

Result of First Ballot.

The result of the first ballot to select the twenty architects who will be eligible in the second ballot is declared by the scrutineers, Messrs. A. W. S. Cross, V.P.R.I.B.A., and E. A. Rickards, F.R.I.B.A., as follows:—

1. Edwin L. Lutyens, F.R.I.B.A., London.
2. Ernest George, P.R.I.B.A., London.
3. Henry T. Hare, F.R.I.B.A., London.
4. Ernest Newton, F.R.I.B.A., London.
5. Leonard Stokes, F.R.I.B.A., London.

HALF INCH DETAIL OF MAIN FACADE.

LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. MEASURED WORK BY H. J. ROWSE, TRAVELLING SCHOLAR.

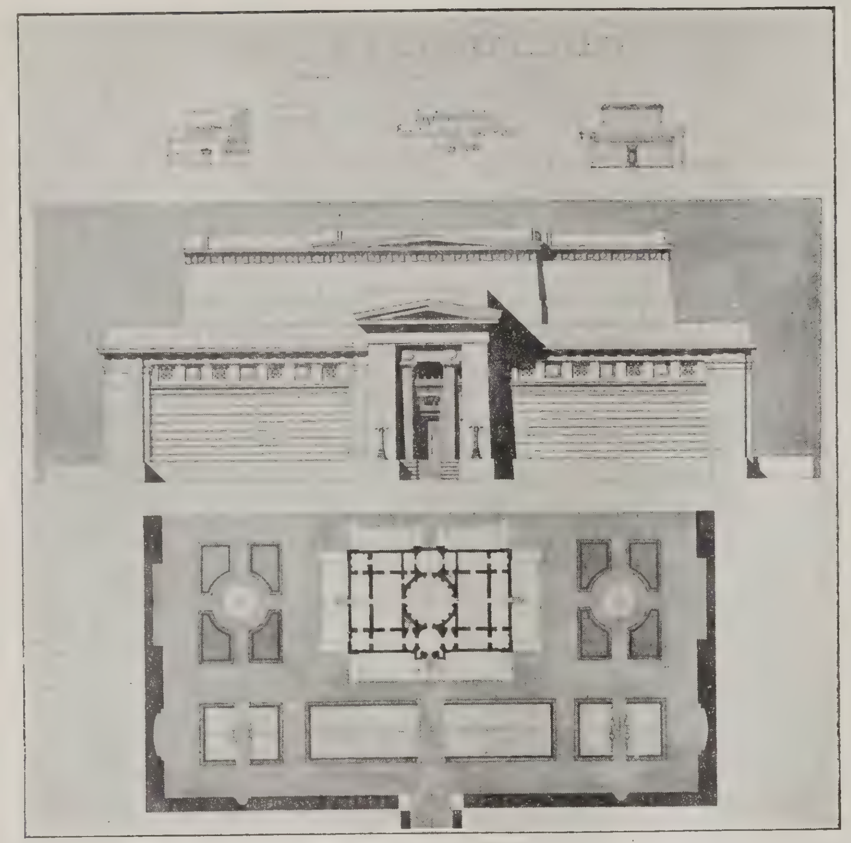
UNIVERSITY OF LIVERPOOL SCHOOL OF ARCHITECTURE.

The annual exhibition of students' work, held in the Tate Library of the University, this year furnishes striking evidence of the extent to which the modern appreciation of the best in classic has advanced within the last five years.

With a sanity of perception, for which we too often vainly seek in other quarters, Prof. Reilly has trained his students in the only tradition relevant to our present-day civilisation, and has imbued them, as our inspection of their work convinced us, with a breadth of view and sincerity of purpose to which we in England have become strangely unaccustomed. The designs exhibited betray none of that triviality of conception and crudity of execution which we fear the Americans have come to associate so justly with architecture in this country. A comparison of the students' designs, moreover, shows that this competent maturity has not been attained by a rigidly stereotyped system of training tending to produce mere facility within definite limitations. Rather there is a refreshing individuality of manner, a distinctly personal note in their productions which is yet far removed from cheap eccentricity in detail. The work exhibited is divided into two classes—that submitted for the final certificate examination, and that for the final examination for the degree of B.A., with honours in architecture. Candidates in both classes were eligible for the various travelling scholarships offered.

Of the work of the certificate students, that of Mr. E. T. Forster appeared to us to be on the whole the most advanced. His designs for a Campo Santo and an Art Gallery show a definite Greek tendency, and an appreciation of Fifth Century Hellenic detail which is no doubt mainly due to his careful measured studies of some of the monuments of the Greek revival in the district. Another certificate student, Mr. E. C. Lemon, whilst apparently not so far advanced, still gives considerable promise. He appears to have taken Sanmichele as his model in academic design, and has attained something approaching facility in the latter's technique.

As might naturally be expected, the designs of the final degree students are altogether more advanced, and display a greater knowledge than those of the certificate men. Where both classes have been given the same problem, the solution of the former is invariably more elaborate and competent, and there is evident a more cautious striving after development along individual lines. As an illustration of this, we reproduce a sketch design for a terrace and pavilion to a promenade in a public park, submitted by Mr. Lionel B. Budden, a study which appears to combine the composition of Alexander Thompson with the refinement of



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. DESIGN FOR AN ART GALLERY BY LIONEL B. BUDDEN, B.A. HONS. STUDENT. FINAL.

Burton. In this student's later work a more American tendency is evident, and his design for an art gallery, though in its main lines again reminiscent of Thompson, is obviously, in so far as the detail is concerned, influenced by trans-Atlantic models.

The same subject of an art gallery is treated by another degree student, Mr. H. A. Dod, in an entirely different fashion, and is admirably worked out in rendered drawings of very agreeable colour. In fact, these two designs, considered with that of an intermediate degree student, Mr. E. Prestwich, who also presents a solution of the art gallery problem that is a happy combination of scholarship and originality, constitute in themselves convincing proof of the really big scope which Prof. Reilly gives to his students whilst yet insisting on constant restraint and absolute freedom from affected eccentricity.

A genuinely appropriate design for a country inn is the work of Mr. Sydney H. Colton. In this, as in his other domestic work, he is distinct from the rest of the degree students by his choice of a purely Georgian technique, due, as his measured plottings would appear to show, to early contact with the examples of that style in which the City of Liverpool is so rich. The careful working drawings (⅛in. scale and ½in. scale) of the design are, however, typical of all the domestic work produced in the school, in that they are well figured and written to, and their construction very fully considered.

The final design examination, conducted as in the Ecole des Beaux Arts, with separate rooms for the candidates, lasted, we were informed, one calendar month, during which time each student was required to complete an adequate number of explanatory-rendered drawings of a design for a villa and garden, "intended for a wealthy man of artistic and literary tastes." One of the designs, that by Mr. Dod, the author of the art gallery to which we have referred above, is a thoroughly ingenious adaptation of the Petit Trianon, and with its garden makes an exceedingly pleasant composition. In Mr. Budden's conception of the subject, approached from another point of view, we see what we regard as a consistent application of his manner of expression to lighter needs.

Among the optional subjects for the final degree students, is included modelling. We reproduce two examples of work cast, which may be taken as fairly typical of the character and quality of the bulk of that exhibited—the one a faithful rendering by Mr. Dod of the famous Lysiciates scroll, the other a design for a herm-head, by Mr. Budden, being a detail of an accessory in a scheme for an Italian garden.

From a mass of work exhibited by first year certificate and degree students, we have selected for reproduction a design for a mausoleum, by Mr. W. A. Allen. Particularly notable in the first year work is the composition in "the orders" which has been recently introduced. Instead of the mere dry copying from plates, Prof. Reilly has made each student compose a sort of frontispiece with the order and its details in the foreground, whilst the building, from which it is taken, and an imaginary landscape, form the background. Some of these have been elaborately coloured, and make very effective drawings, besides introducing into what has hitherto been a rather dull subject, the element of fancy and design.

An interesting feature in the exhibition is the extraordinarily careful measured drawings made in Italy by a former travelling scholar, Mr. H. J. Rowse, of which we reproduce two examples.

Mr. J. J. Shannon, A.R.A., was at a general assembly of Academicians and Associates last Wednesday elected a Royal Academician. Mr. Shannon, who was born in New York State in 1862, came to England in 1878, and was elected A.R.A., in 1897. His work has been mainly in portraiture.

* * *

The Lambeth Borough Council has been awarded £81,342 by the arbitrator for their portion of the Lambeth foreshore required by the London County Council for the site of the New County Hall. The amount claimed was £179,138.

Buildings in Progress and Completed.

BISHOP AUCKLAND.—The foundation stone of the new Hippodrome was laid recently. The building, which is expected to be opened in December, is to be of brick with stone dressings, with seating accommodation for 1,800 persons, and will cost over £10,000. The architects are Messrs. J. J. Taylor and Minor, A.R.I.B.A., and the contractors are Messrs. Nicholds and Reynolds, Limited, Westminster.

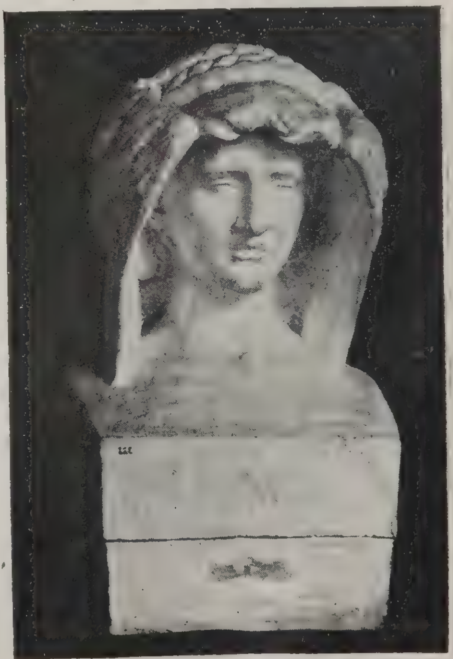
BLACKBURN.—A new church, St. Jude's, is shortly to be erected here, from the design of Messrs. A. R. Gradwell and Son, architects. Seating accommodation will be provided for 603 worshippers.

BOCKING.—Memorial stones of a new extension to the Wesleyan Schools have been laid. The cost of the extension will be about £500. The plans have been prepared by Mr. Albert Thompson, Cross Roads, and the work is to be completed by Mr. James Greenwood, builder; Mr. Ineson Taylor, joiner; Mr. W. H. Greenwood, plumber; Mr. A. Sunderland, slater; and Mr. J. Brearley, plasterer.

CREWE.—A new intermediate school—to accommodate 350 scholars—has been built in Ruskin Road. It is intended for the youth of both sexes who have won scholarships. The cost has been about £20,000. Mr. Beswick, of Chester, is the architect.

DRAX.—The new buildings at the Grammar School have been erected to plans prepared by Mr. H. B. Thorpe, of Goole, and the contractor was Mr. Walker, of Goole. The teaching premises have cost £3,800, and the boarding part about £4.500.

DUBLIN.—The new office building, No. 9, College Green, for the Sun Insurance office, is now completed. The building is designed in the Italian Renaissance style. The basement and ground floor are faced with Ballynockin granite. The first, second, and third storeys are faced with Mount Charles stone, worked in Dublin. Two wrought iron and granite balconies of elaborate design front the first storey windows. Above this storey appear Ionic columns with carved capitals. The cornice has carved medallions. The fourth floor windows are in the slope of the roof, and are concealed by a balustrade parapet. All the floors are of fireproof construction. Passing through a panelled vestibule, the visitor



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECT URE. "HYPNOS." MODELLING FROM THE CAST LIONEL B. BUDDEN, B.A. HONS. STUDENT. FINAL

LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. LYSICRATES SCROLL. MODELLED FROM THE CAST BY H. A. DOD, B.A. HONS. STUDENT. FINAL.

finds the space appropriated to the reception of the public paved with alternate squares of green Tinos marble and white Pentelikon. The rest of the general office is floored with wainscot oak, and the walls are panelled to a height of nine feet with Cuban mahogany, and above that are lined with pale pink Skyros marble set in frames of Pentelikon. The chimney-pieces are adorned with wreaths, shields, and flowers carved in limewood. The hearths and grates are in green Cipollino and Verde Antico marbles. Two electroliers present an adaptation of an eighteenth century chandelier. An Otis passenger lift serves from the public space to all the floors. The desks and other fittings and the counter are of mahogany. A marble staircase, with a wrought iron balustrade and moulded brass handrail, leads from the committee office to the upper floors. The first floor is devoted to the managerial department, board-room, and waiting-room, which are all panelled with Cuban mahogany and floored with wainscot oak. The board-room has carved limewood ornament to the chimney-piece. The second and third floors are fitted as offices for the companies. The fourth floor contains caretaker's apartments. The building is lit with electric light throughout on the most up-to-date lines. This, together with an elaborate telephone system, has been installed by Messrs. Curtis and Son, of Dublin. The heating throughout is by open fires. Mr. Horace Porter, of Russell Square, London, architect to the Sun Insurance Co., was the designer, and the builder was J. R. Thompson, of Fairview, Dublin.

EDINBURGH.—The Town Council have had under consideration plans, prepared by Mr. R. S. Lorimer, A.R.S.A., for the new chapel for the Order of the Thistle, to be added to St. Giles's Cathedral. The plans, which show a chapel 33ft. long, 17ft. wide, and 35ft. high to the apex of the vaulting, have already been approved by the Lord Provost's Committee.

EAST COWTON.—The foundation stone of a new established church has been laid. The cost will be about £1,850. To Mr. Eccles, of Messrs. Woolfall and Eccles, Liverpool, was entrusted the preparing of plans for the new church. It is early English in style. The church will be about 60ft. by 30ft., and the seating accommodation will be for 150. It will be built of Northallerton brick, with stone facings from the Darleydale Quarry, Derbyshire. The contractor is Mr. T. Boyd, of Darlington.

FENNY STRATFORD.—A new Wesleyan Church, to cost about £2,500, is in course of erection. Messrs. Ewen Harper and Bros., of Birmingham, are the architects, and Mr. A. P. Hawten, of Northampton, the builder.

FROSTERLEY (WEARDALE).—The new church hall which was opened here recently provides accommodation for 260 persons. Built to the designs of Mr. W. Bedlington, the hall is constructed of stone taken from the local quarries, and has cost £1,000.

GREENFIELD, near Holywell.—The Flintshire County Council have accepted the tender of Messrs. E. Blane and Son, Connah's Quay, at £4,100, for the erection of a new council school here.

HASLINGTON.—The church is to be rebuilt, the portion in hand comprising the chancel, vestry, heating chamber and organ chamber, at a cost of £1,400. Mr. Reginald T. Longden, Burslem and Leek, is the architect, and Mr. Matthews, Nantwich, the builder.

LEEDS.—The Hunslet Moor Council School has been erected consequent upon the condemnation of the Hunslet St. Peter's Council schools by the Board of Education. The school consists of two blocks, one of which provides accommodation for 360 girls on the ground floor, 360 boys on the upper floor, the other providing for 388 infants on the ground floor and containing handicraft, cookery, laundry, and house-wifery centres on the upper floor. A central hall has been provided for each department, and the classrooms are mostly arranged to accommodate sixty children. The buildings are lighted throughout by electricity, and the drainage and sanitary appliances are of the most modern type. The school has been built with local bricks and stone, under the supervision of the committee's architect, Mr. Fred. Broadbent. The total cost of the site, buildings, and fittings will be about £20,000.

LONDON (BARNSBURY, N.).—The Bishop of London recently opened a new mission hall, which, including the site, has cost £4,100. The architect was Mr. J. S. Alder, and the builders were Messrs. Dove Brothers, Islington.

LONDON.—The London County Council have approved of the plans of a new concert hall which is to be erected in John Street and Durham Street, Adelphi. The building, which has been designed by Messrs. Hayward and Maynard, architects, of John Street, is to be adapted from a portion of the old Coutt's Bank, and will accommodate about 400 people.

LONDON.—Many important alterations have been made at the Hippodrome since it was closed some months ago. The arena is covered with seats, which can be removed when occasion demands, and the orchestra, which formerly occupied a position in the circle, has been shifted to the usual place in front of the stage. The boxes have been so aligned that a clear view of every part of the stage can be obtained. The circle has been enlarged and supplied with balustrades; and, on either side of a new cinematograph box which occupies a space formerly known as the crush room, there are now spacious entrances to the stalls. The proscenium, however, has undergone the most important alterations. It has been brought forward about 20ft., thus giving the stage a depth of 40ft. and a width of 74ft. from wall to wall, with a width of 44ft. at the opening. The stage has been divided into three sections, which allow of an entirely novel manner of working.

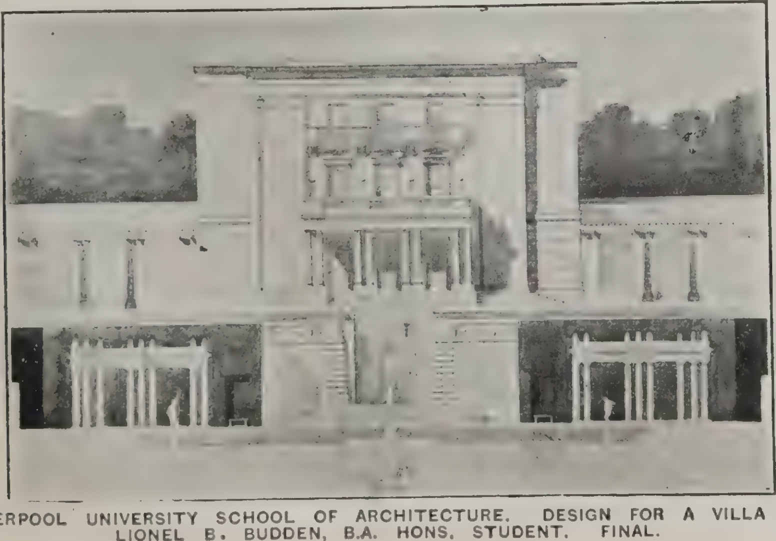
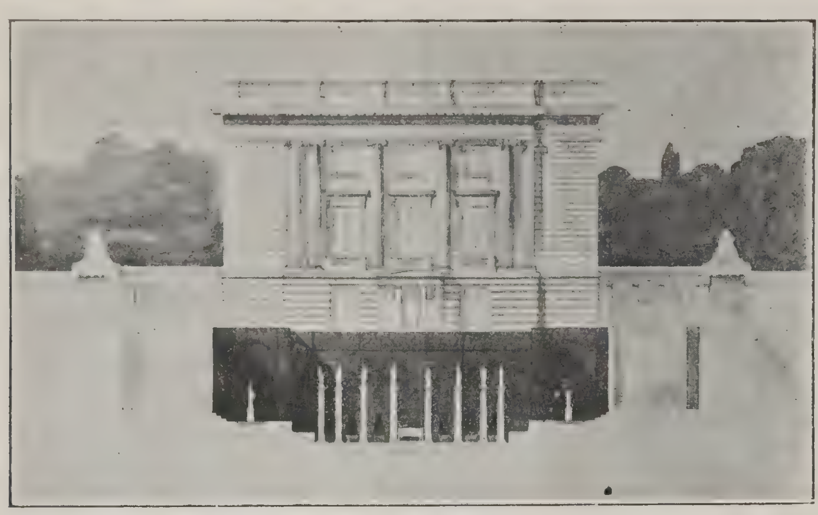
LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. LIONEL B. BUDDEN, B.A. HONS. STUDENT. FINAL.



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. DESIGN FOR A VILLA BY LIONEL B. BUDDEN, B.A. HONS. STUDENT. FINAL.

NORTHAMPTON.—The new Holy Trinity Church, which was consecrated recently, is a further notable example of modern perpendicular Gothic. The church consists of a nave, with chancel of equal width, north and south aisles with porches, a baptistery at



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. DESIGN FOR A VILLA BY H. A. DOD, B.A. HONS. STUDENT. FINAL.

the west end, and a Lady chapel on the south side of the chancel; and the cost, including furnishing, will be about £10,000. Mr. M. H. Holding, A.R.I.B.A., and his son were the associated architects, and the general contractor was Mr. R. Cosford; all three gentlemen being of Northmapton.

OBAN.—A sanatorium for Argyllshire has been opened here, accommodation being provided for 40 patients. Mr. Neil Gillies, of London, is the architect.

ONLLWYN.—A new Welsh Congregational Church is being erected here from the designs of Mr. W. Beddoe Rees, Cardiff. The church, which will seat 620, has a school adjoining it for about 300, and will cost about £3,000. Messrs. E. Turner and Sons, Cardiff, are the builders.

QUILTY (IRELAND).—The cost of a new church, which is in course of erection here, is estimated at about £1,900. Messrs. O'Malley and O'Rourke, of Limerick, are the architects, and Mr. John Ronan, of Kilrush, is the builder.

SUTTON-IN-ASHFIELD.—The foundation stone of St. Michael's Church was laid recently. The chancel and vestry were built about 24 years ago, and a temporary corrugated iron nave was added some time later. Mr. Louis Ambler, F.R.I.B.A., prepared plans in 1905 for the completion of the church, and the work is now being carried out. The church is in the early English style, and provides sitting accommodation for 600 persons. Messrs. John Thompson and Co., of Peterborough, are the builders.

THORNTON HEATH.—The foundation stone of a new Baptist Church, which is to replace the existing temporary building, has been laid. The new building, which is to take the form of a memorial to the late C. H. Spurgeon, has been designed by Messrs. George Baines and Son, of 5, Clement's Inn, Strand, in the Gothic style. The church, when completed, will seat 830 persons—530 of which will be accommodated on the ground floor—and it is estimated to cost £4,000.

WICK.—At a cost of about £8,000 a new higher grade school is being built from the designs of Messrs. D. and J. R. McMillan. The contractors for the work are:—Mason work, D. H. Harper, Wick; carpenter work, Hendry and Keith, Aberdeen; slater work, George Farquhar, Aberdeen; plasterer work, James Smith, Wick; plumber work, John Blaikie and Son, Aberdeen; painter work, John Mason and Son, Aberdeen; glazier work, Robert Shearer, Wick; iron beam work, Redpath, Brown, and Company, Edinburgh; gates and railings, Wares and Company, Wick; heating engineer, Robert Tindall, Aberdeen.

WIMBLEDON.—The consecration of the eastern portion of the new church of St. Matthew, the foundation stone of which was laid about a year ago, was performed recently. The completed church has been designed by Mr. E. C. Shearman, A.R.I.B.A.

WINDSOR.—Plans have been passed by the Town Council for the re-erection of the theatre, which was partially destroyed in February last. The new building, which is to be in the Renaissance style, will have three frontages—Thames Street, Thames Avenue, and River Street—and the purchase of site and adjoining properties, the erection of the building and the furnishing will involve a capital expenditure of £20,000. The combined accommodation of pit, stalls, private boxes, and a spacious gallery, will be 1,150 persons. The architect is Mr. Henry Percival, who has designed a number of other theatres.

RIO DE JANEIRO.—The Municipal Theatre, just completed here from the designs of Senhor F. de Oliveira Passos, is, with the exception of the Paris Opera House, the most expensive entertainment building in the world, having cost, exclusive of the site, £678,500. Of this some £60,687 has been sunk in machinery and electrical plant, mostly of English make, and £57,437 on marble and bronze. The principal facade is in Italian marble and Rio granite, surmounted by a copper dome over the centre of the building crowned by an eagle of gilt bronze, whose outstretched wings measure nearly 20ft. across. The building is spoilt by the stage portion finished in a slate-colour stucco. The proscenium opening is 38ft. high and 43ft. wide, and the stage is enormous and equipped with the latest electrical machinery. The grand staircase is carried out in marble, onyx, and gold.

Proposed New Works.

BATLEY.—While undergoing cleaning operations recently, the roof of the Parish Church was discovered to be in an alarming condition of decay. For some time past it has been the intention of the Vicar to do away with the plaster underdrawing, and to restore the roof to its original condition; but this serious discovery now renders imperative a complete overhauling of the whole fabric, and it is certain that an entirely new roof will have to be made.

BIRKENHEAD.—The Education Committee have recommended the acceptance of Mr. Peter Rotherwell's tender of £17,306 for the erection of a new school. The sanction of the L.G.B. for a loan of £18,723 is to be asked.

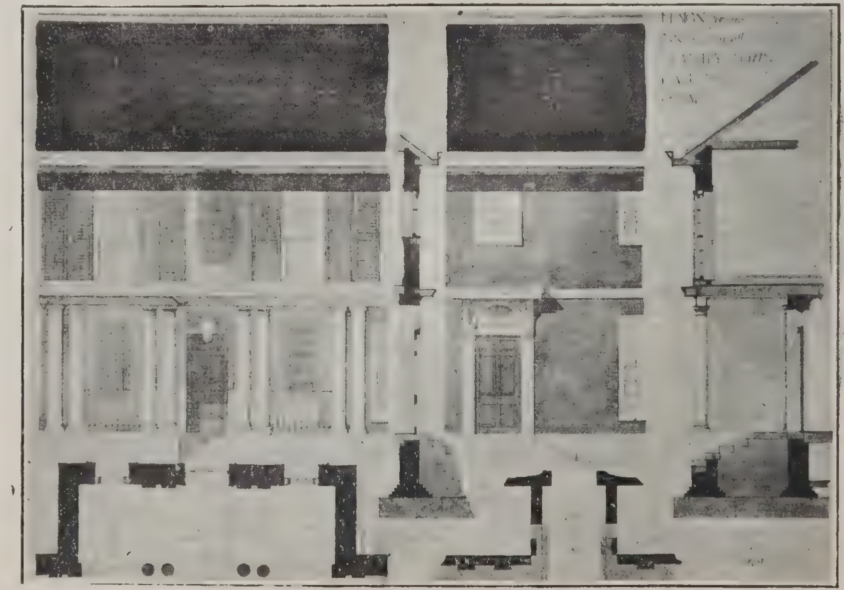
BOURNEMOUTH.—An anonymous gift of something over £3,500 has been received, to defray the entire cost of a new children's ward at the Royal Boscombe and West Hants Hospital.

CROYDON.—A scheme has been under discussion for the widening of North End at a cost of £130,000. This involves the demolition of the Whitgift Hospital which was erected in 1596.

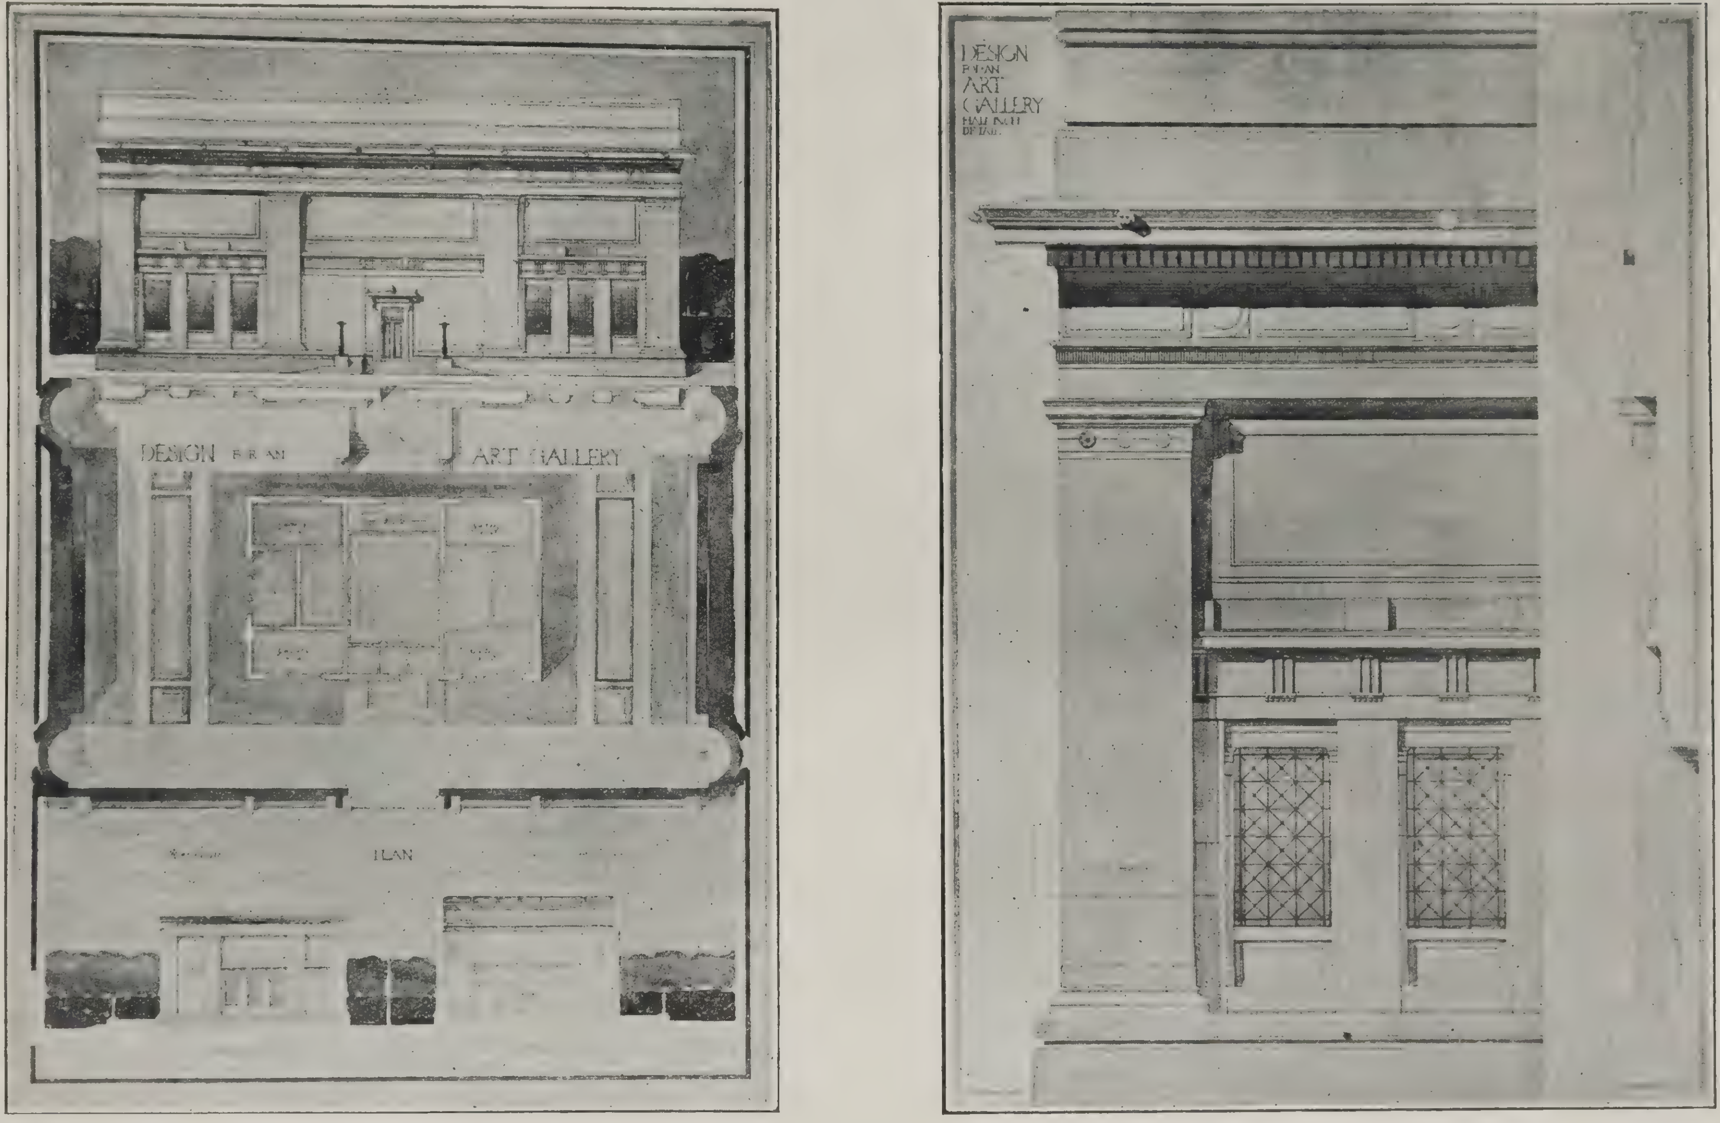
DURHAM.—The following plans have been passed by the Council, with the exception of those sent in by the Aged Miners' Homes Committee, G. Innes, and M. Meehan:—Dwelling-house at High Pittington for Thos. Simpson; alterations to Black Bull Inn, Cassop Colliery, for North-Eastern Breweries, Ltd.; addition to buildings, Sherburn Hospital, for the Governors of Sherburn Hospital; 20 cottages at Ushaw Moor, for the Aged Miners' Homes Committee; 6 dwelling-houses at Auton Stile, for Gabriel Innes; 5 dwelling-houses at Auton Stile, for M. Meehan; 1 dwelling-house at Lowes Barn, for Miss Waite; 2 dwelling-houses at Framwellgate Moor, for B. Binney and R. Davison.

FULWOOD.—A new Wesleyan Church is in contemplation here, to cost about £3,500. The complete scheme, which includes a Sunday school, is estimated to involve a sum of about £6,000. The designs, prepared by Mr. Fred Howorth, of Leyland, were selected recently in competition.

GREENOCK.—The Dean of Guild Court has passed plans for the erection of a new church in Dempster Street. Warrant has also been granted to the School Board to convert the Allan Ker School in Ann Street into an engineering school and laboratory. Permission to erect two tenement buildings in Belville Street has been granted to Messrs. R. Aitkenhead and Sons.



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. DESIGN FOR AN INN IN A COUNTRY TOWN, BY SYDNEY H. COLTON. B.A. HONS. STUDENT. FINAL.



DESIGN FOR AN ART GALLERY
PLAN
DESIGN FOR AN ART GALLERY HALF INCH DETAIL.

LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE.

DESIGN FOR AN ART GALLERY BY H. A. DOD, B.A. HONS. STUDENT. FINAL.

HEATHFIELD (ESSEX).—A proposal has been made by the Finance Committee that the sanction of the L.G. Board be obtained for borrowing the sum of £2,752, which is estimated to cover the cost of erection and equipping of new school buildings, and the erection of a master's house.

HIGHFIELD.—The Keighley Education Committee are considering the erection of a new mixed school here.

HUNTINGDON.—The L.G. Board has held an inquiry into the proposal of the Hunts County Council to borrow £2,000 for the purchase of a portion of the Cromwell House Estate as a site for county buildings.

LIVERPOOL.—Mr. Andrew Carnegie has promised £19,000 for the erection of two libraries and three reading-rooms upon the Corporation undertaking to find the sites and the cost of maintenance.

LONDON.—The County Council contemplates the erection of 1,081 cottages on the Old Oak Common Lane Estate, Hammersmith, and two schools. Also a further 438 cottages and a school on the Totterdown, Tooting, Estate. 100 cottages are to be built on the Council's Tottenham Estate.

LONDON.—The site for a new fire station at Bow has been purchased, and work will commence in the autumn.

LONDON.—It is proposed to enlarge the Clerkenwell fire station at an estimated cost of between £12,000 and £13,000.

LONDON.—The Southwark Board of Guardians propose to raise a loan of £50,000 to acquire the Bow Infirmary, pressure on their establishments having resulted in overcrowding.

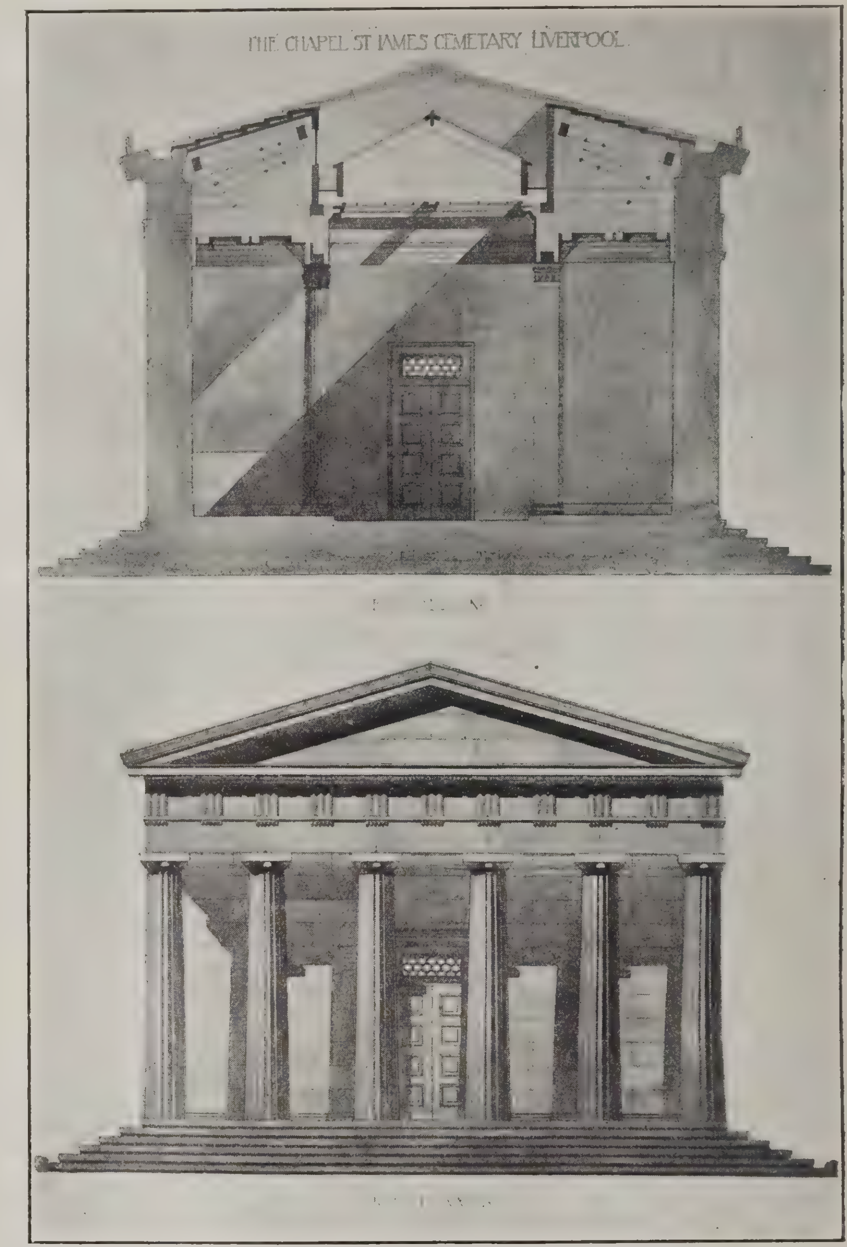
LONDON.—At a meeting of the Middlesex County Council, held at the Guildhall, Westminster, it was agreed to appoint a special committee for the purpose of considering the desirability of altering and improving the present Guildhall, in preference to the erection of an entirely new building, which, including the clearing of the site, was estimated to cost £90,000.

LONDON.—The authorities of Bedford College have applied to the London County Council for a building grant of £20,000 to assist the college in the erection and equipment of new buildings in Regent's Park, at an estimated cost of £100,000. The Education Committee have suggested that the Council should consider the question of making provision for a sum of £5,000 a year for four years, provided that certain conditions are complied with, and that the buildings to be erected in Regent's Park are maintained in perpetuity as a college for the education of women.

LONDON. — The Hackney Borough Council have recommended the passing of plans for building five double-tenement dwelling-houses on the north-east side of Holmbury View, westward from Big Hill, Clapton, on the application of Mr. F. Collins; seventeen dwelling-houses on the western side of Castlewood Road, seventeen dwelling-houses on the eastern side of Moundfield Road, and thirteen dwelling-houses on the western side of Moundfield Road, northward from Ravensdale Road, on the application of Mr. Percy Roche; also one bank, with dwelling-house over same, and twelve shops with residential flats over same, on the eastern side of Stamford Hill, southward from Upper Clapton Road, on the application of Messrs. Edmondson, Ltd.

NEWPORT (MON.).—Objection having been raised to the appointment of an architect to prepare plans for workhouse accommodation, Mr. R. H. Williams, a L.G. Board inspector, urged that Newport should not hesitate when the L.G. Board had given its consent—since the publication of the Poor Law Commissions' report—to the erection of buildings which would cost £60,000 or more. After some discussion, it was resolved to advertise for an architect.

NORWICH.—Towards the extension of the Norfolk and Norwich Hospital, the King has given 250 guineas.



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE.
MEASURED WORK BY E. D. FORSTER FOR FINAL CERTIFICATE.

OBAN.—A warrant has been granted by the Dean of Guild Court, for the execution of alterations and additions at the police station buildings.

PORTSLADE.—The U.D. Council are considering the question of erecting a Town Hall, and of finding a site for it.

TWICKENHAM.—The County Council have decided to recommend that the suggested scheme for the rebuilding of the Guildhall be not adopted; and that the present building be improved and adapted to the requirements of the Council.

TUNSTALL.—The U.D. Council contemplate the erection of a tea pavilion and shelter in the park at a cost of £1,750.

WORTHING.—The West Sussex Education Committee are considering the question of a new secondary school to be erected here.

WEYMOUTH.—The Education Committee of the Town Council are considering sites for a new school for 250 boys.

YARMOUTH.—The Town Council is considering a scheme prepared by the Borough Surveyor for Public Baths. The plans provide for a first-class swimming bath, 100ft. by 34ft., a second-class bath, 75ft. by 26ft., cleansing baths, slipper baths, also Turkish and Russian baths and necessary offices.

At the last meeting of the London County Council it was recommended by the Main Drainage Committee that the tender of Messrs. G. Shellabear and Son, of Plymouth, for the construction of the Southern low-level sewer No. 2, from Deptford to Battersea, at a cost of £473,416, be accepted. Mr. E. G. Easton, the chairman of the committee, however, stated that he had that afternoon received an intimation from the contractors that their tender would be withdrawn, as they were unable to place the order for cast-iron at the price anticipated. He therefore suggested that the Council should adopt the estimate of expenditure on capital account of £487,000 submitted by the Finance Committee, and that fresh tenders be invited immediately after the recess, in order to provide work during the winter. Captain Hemphill said that they were going to commit the Council to giving a contract of nearly half a million to a ring of contractors. They should consider whether the time had not come when they should be masters of the contractors, instead of the latter being the masters of the Council. It was decided by 61 votes to 35 to refer the whole matter back to the committee.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himself of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable: and it must be understood that both question and reply will, as a rule, be published in these columns

Buildings to Sketch near Bournemouth.

LEYTONSTONE.—H. L. B. writes: "Could you kindly give me particulars of any old buildings (not later than Perpendicular period) worth visiting and sketching, within, say, six miles of Bournemouth?"

Within the rather limited radius prescribed Christchurch Priory is the only mediæval building of real importance, but this is one of the most interesting in the kingdom and worthy of careful study both as a whole and in detail. Special attention should be given to the exterior of the north transept with its fine Norman turret and arcading, the very large thirteenth-century south porch extensively restored, but still lovely—the original Norman exterior of the eastern chapel of the south transept (best seen from the roof of the choir aisle, where the fine flying buttresses of the choir vault may also be studied), and the bluff Perpendicular east end of the Lady chapel. Internally, the Norman nave, charming 13th century work in the Montacute chantry, late 14th-century choir screen, exceedingly interesting stalls and misereres, fine choir vault and reredos, and the several interesting chapels and chantries afford an abundance of material for study. An excellent guide is published by Messrs. George Bell and Sons, price 1s. 6d. Just outside the limit are Wimborne Minster (sadly restored), Beaulieu Abbey (considerable remains embodied in residence of Lord Montague, and 13th-century refectory now serving as parish church), and further afield are the several interesting village churches in Dorset, around Bere Regis.

G.

Cleaning Cement and Oil off Tiled Floors.

J. M. L. (HARROW) writes: "Can you give me any information as to the best way of cleaning red tile floors from Portland cement particles and also from oil and grease?"

Oil stains may be removed by covering the spots with Fuller's earth ¼in. thick, and putting a hot iron upon the top; an ordinary domestic flat iron heated as if for ironing would be suitable. Heat is necessary, but if excessive it will crack the tiles. Any projecting portions of Portland cement should be carefully chipped off with a sharp cold chisel, then with a little fine sand, water, and red ochre the whole surface may be rubbed over with a piece of red tile about 4 to 6 inches square, dwelling a little longer on the cement stains than on the other parts.

HENRY ADAMS.

Encroachment.

MILFORD HAVEN.—L writes: "The outline sketch (not reproduced) shows the end elevation of a house built on a plot of land leased from an estate company. The walls of the house on this side are built in a direct line with the garden wall and form the boundary of the site. The plans for the house were submitted to the surveyor to the estate, who approved of same. Now the house is built he complains that the fascia board and gutter are fixed overhanging the wall, although fixed tight to it; and threatens either to charge extra ground rent for the strip of ground covered by the gutter, or to take a strip of land 6ins. wide off our boundary on the other side. Is this legal? Can we be forced to alter same? Ought we not to have been notified at the time the plans were approved?

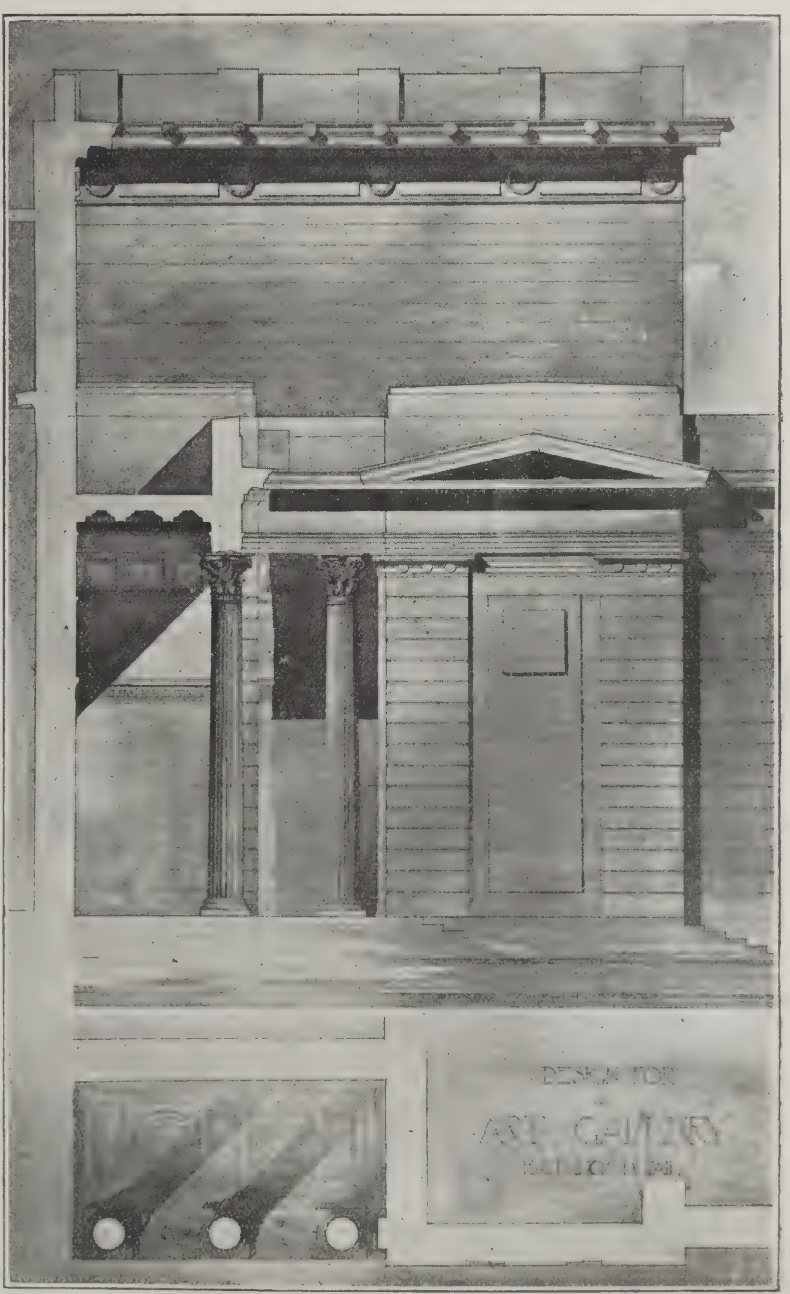
The projection of your fascia board and gutter is of course an encroachment upon the neighbouring property, and the owner of that land possesses the right to call for its removal, or, in default, may remove it himself, or enter an action against you in respect of the damage sustained by reason of the trespass. I advise you to come to terms with the surveyor to the building estate at once, either taking a narrow strip of land to cover your encroachment, or paying a small acknowledgement rental for it. The fact that the plans were submitted and approved has nothing to do with the matter. It was no doubt presumed that you only intended to build on your own land.

F.S.I.

Timber Roof Trusses.

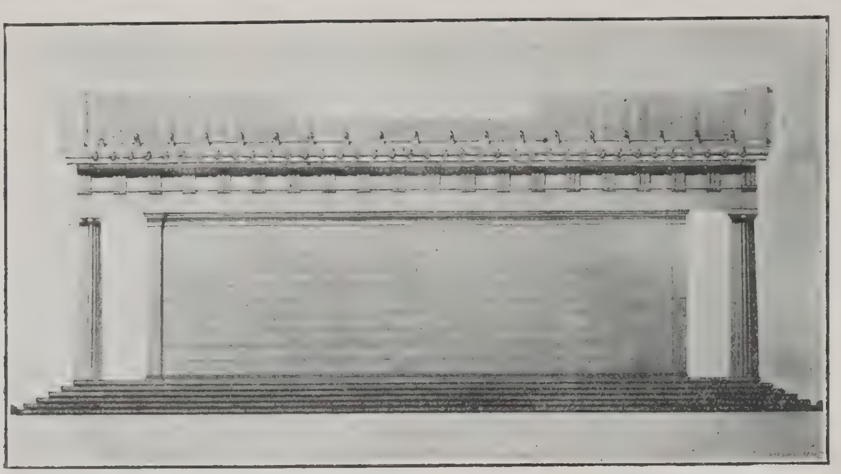
LONDON (DULWICH, S.E.).—F. S. writes:—"With reference to the reply to 'Glasgow—J.W.S.' (see our issue July 7th, p. 9.), I think a very interesting question was asked by the enquirier when he said, 'What is the easiest way to get sizes of the various timbers in the roof truss?' I rather wish that your expert had given a fuller reply to this question as I think the subject is of general interest."

Tables are given in many text-books of the sizes of the timbers of ordinary trusses such as king post, queen post, etc., which with the exercise of a little preliminary knowledge and common sense can be utilised for ascertaining the scantlings of simple trusses of intermediate spans, or of varying distances apart, but the introduction of any irregularity of loading or other special feature at once renders calculation necessary if an economical design of sufficient strength is required. Certainly much constructional work has been done without calculations, and sometimes failure occurs; but frequently the difficulty is overcome by unnecessarily large scantlings being adopted, in which case, although he is probably not aware of the fact,



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE.

E. PRESTWICH. B.A. HONS. STUDENT. INTERMEDIATE.



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE.
MEASURED WORK: MORTUARY CHAPEL, ST. JAMES CEMETERY, LIVERPOOL.
E. D. FORSTER. FINAL CERTIFICATE STUDENT.

the client is paying an increased price for his work for the privilege of employing a man who either cannot or will not make the calculations necessary to arrive at the maximum of efficiency and economy, and for which "professional" services the same commission is paid as though the work were properly designed; or in the alternative the information is sought for (generally under an assumed name and misleading address) in the enquiry columns of the technical papers by the payment of a few pence to cover postage expenses. Happily these form only a small proportion of the querists.

There are general rules observed in settling scantlings, such as that all timbers should be of one thickness if possible, but they would relate more to the appearance than the strength of the truss, and experience forms a good guide, but a very considerable majority of the replies to questions relating to trusses demand the preparation of stress diagrams and calculations in detail; many of them are most complicated and the preparation of the answer may take from a few hours to several days, and obviously this amount of labour would not be incurred if the problems were readily solvable by rough and ready means. Even when the scantlings are correctly ascertained the whole value of the labour may be lost by defective formation of the joints and the greatest care is necessary to ensure safe and sound construction.

HENRY ADAMS.

Bird's-eye View: Duresco.

KINGSTON-ON-THAMES.—NEMO writes: "(1) The enclosed sketch [not reproduced] shows a building estate which has elegant slopes. A 'bird's-eye' view is required which will exhibit these natural slopes to the best advantage. Apart from shading, how is it possible to do this? (2) When using 'Duresco,' or any washable distemper, is it necessary to stipple the surface in order to obliterate brush marks?"

(1) A bird's-eye view gives the least possible chance of clearly indicating slopes in the ground, unless there are horizontal lines, such as eaves of buildings, walls, fences, etc., which can be made by contrast to afford evidence of the sloping nature of the surfaces. If the view in question is taken from the south-west, however, there appears to be no reason why a fairly low horizontal line should not be taken, as the direction of the fall will help to display the extent of the estate. To accurately show the levels, the bird's-eye view should be properly set up in perspective with certain points (probably the corners of the roads) truly plotted as to position in plan and vertical level. If a sufficient number of points are so found, they may be joined up and will give the effect correctly.

(2) It is not usual to stipple the surface of washable distempers to obliterate brush marks, but if the material is properly applied in accordance with the various maker's directions (which differ considerably), these are very inconspicuous.

G.

Length and Thickness of Walls.

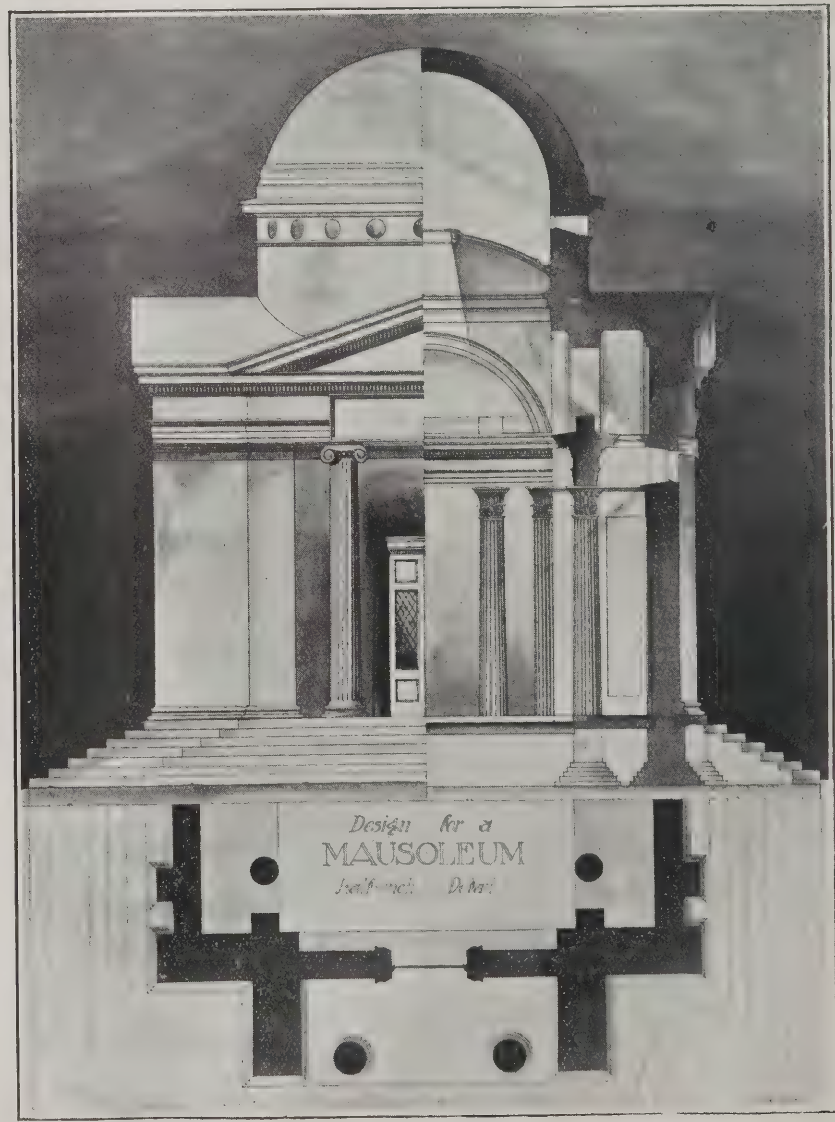
SURBITON.—E. T. writes: "I am about to erect a house, and a question has arisen with the district surveyor as to the definition of lengths of 9in. walls with relation to cross walls. I contend that the entire length of wall is divided into three distinct lengths by the chimney breasts. The surveyor, however, contends that the whole length is one wall only, and that the 4½in. wall must be made 9ins. to comply with the by-law, which prohibits any 9in. wall over 30ft. long without a 9in. cross wall. Your opinion in the matter would be esteemed."

There is no doubt whatever that the surveyor is right in contending that this is a wall of more than 30ft. in length, and that the 4½in. cross wall must be thickened to 9ins. before the building complies with the by-laws. Chimney breasts are not cross walls within the meaning of the Public Health Acts. The only definition of a cross wall of which I am aware is contained in "The London Building Act" of 1894, and I quote it here as being to a certain extent germain to the case:—"The expression 'cross wall' means a wall used or constructed to be used in any part of its height as an inner wall of a building for separation of one part from another part of the building, that building being wholly in, or being constructed or adapted to be wholly in one occupation."

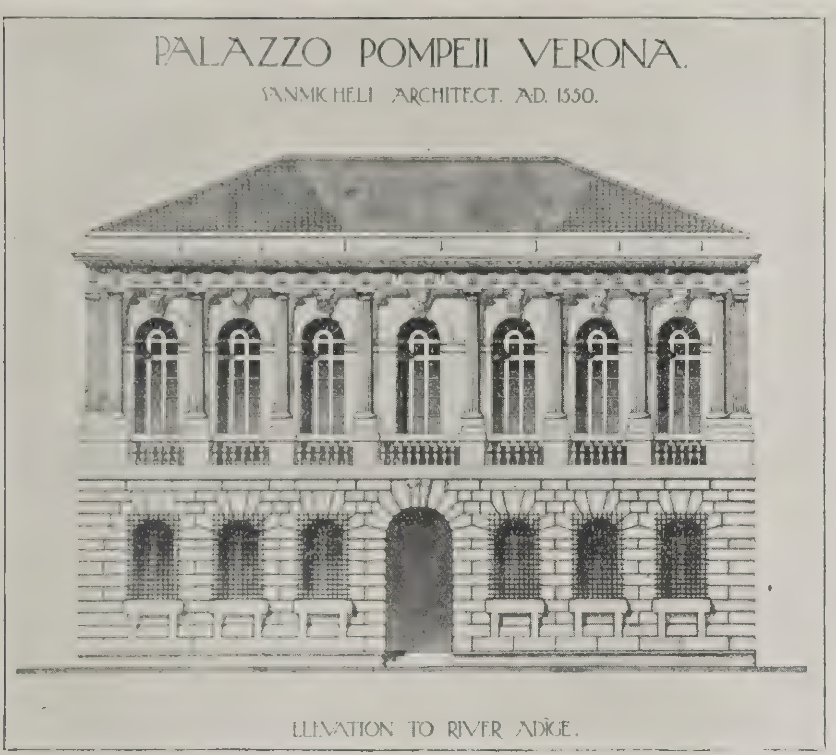
F.S.I.

Drainage of Old Houses.

YORKS.—J. S. R. writes: "A block of property erected about 1870. The local inspector of nuisances has now sent notice to the owner demanding that the undermentioned



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE.
W. A. ALLEN. 1ST. YEAR CERTIFICATE STUDENT.



LIVERPOOL UNIVERSITY SCHOOL OF ARCHITECTURE. MEASURED WORK BY H. J. ROWSE, TRAVELLING SCHOLAR.

alterations should be made at once. (1) All the rain water pipes in the yards, which are now connected direct to drain, should be disconnected and made to discharge over a trapped gulley; (2) all the rain water pipes on the front of the houses which are now connected direct to the drain are to be disconnected from the drain, and are to be connected to pipes or channels fixed in the adjoining footpath and made to discharge in the gutter of the public roadway. Have the Council the right to demand any of these alterations? None of the tenants have complained of any foul stench arising from any of the fall pipes and they are thus not a nuisance. Should the owner be forced to alter then, would not a gulley trap at the front of the house be preferable, instead of closing up the drain and laying 20ft. of pipes or channels in each case to the edge of the footpath? Should the front R.W.P. ever be taken up, and they are found not connected to a drain, but only taken 3 or 4ft. below the ground, or to a very thick bed of gravel and sand upon which these houses are built, then there will be ample drainage for the rain water without causing the site to be damp and unhealthy, and there will not be the stench complained of by the inspector. In these circumstances, can the Council compel the R.W.P.'s to be taken across the footpath to gutter of roadway? Where can I obtain a copy of the "Public Health Act," 1875, and what is the price of same? Have there been any alterations or amendments to it during the last 30 years?"

Were these houses now in course of erection there is no doubt whatever that the sanitary authority could compel the owner to disconnect his rain water pipes from the foul water sewer, but as they are old houses I have grave doubts as to whether it is reasonable upon their inspector's part to call upon the owner now to do so. I am of opinion that the sanitary authority have no power whatever to enforce this alteration of existing drains, unless they can first prove that a nuisance exists (see Section 91 of 1875 Act), and I should advise the owner to resist such a demand, or to leave the whole thing alone and abide the issue. The principal Act is that of 1875, and is a very long one—it may be obtained at any booksellers or from Messrs. Eyre and Spottiswoode, East Harding-street, London, E.C., the price being, I believe, about 7s. 6d. There are several "Amendment Acts" of later date. I know of no cheap text book on this subject.

F.S.I.

Pressure in Water Company's Main.

BRISTOL.—S. writes: "Is it correct that by an Act of Parliament (Public Health Acts, I believe), the pressure in a water company's main, must not exceed 100lbs. per sq. in.? Should a company's pressure considerably exceed this, what is the course to adopt to make them bring it down to the legal limit?"

The Public Health Acts only deal with the regulations for the supply of water within their districts by the local sanitary authority (and not by a company), and provide (by Section 55 of the Public Health Act, 1875), that "the water may be constantly laid on at such pressure as will carry the same to the top storey of the highest dwelling house within the district or part of the district supplied." Water companies are usually constituted each under a special Act of Parliament, and that Act of course constitutes their authority for all their works—besides this, water companies must also conform to the general Acts of Parliament known as "the Waterworks Clauses" Acts. I am not aware of any such direct provision as that mentioned in the enquiry.

F.S.I.

Wall or Fence?

BRISTOL.—H. H. J. writes: "I am about to build in the suburbs a small cottage of the value of about £200. The boundary walls, being about 300ft. in circumference promise to be rather an expensive item if of a permanent character, so I thought of erecting an open timber fence filled in with wire mesh and training a hedge up same. I should be glad if you would kindly get one of your experts to explain the usual method of doing this, or any other effective method, and price of same."

The brick wall, though its first cost may be greater, will, in the end, probably turn out much cheaper than any substitute. Do the "building regulations" of your purchase allow such a fence as you suggest? A wire fence may be constructed as follows:—Strain a 7 ply galvanized fencing wire along the top and bottom by means of posts at the ends and intermediate supporting stumps. Cost of 7 ply 4 gauge wire (containing about 305yds. run per cwt.) is about 16s. 6d. per cwt. Then attach your galvanized iron netting to this by means of thin lacing wire, cost 3d. per lb., threaded round and round at every mesh, and bury into the ground about 6 inches of the netting at the bottom. The cost of the netting will vary widely according to the mesh you employ; sheep netting of 14 gauge 4in. mesh and 42in. width being about 12s. 10d. per roll of 50yds., whilst rabbit netting of the same width, but with 1¼in. mesh and 17 gauge is 18s. 6d. per roll. "Lock woven" steel wire fencing may be employed (without the straining wire), but it is of course more expensive.

F.S.I.

Graphic Solution of Semi-circular Domes.

"Glasgow" will find in the R.I.B.A. Journal of 21st May, 1904, and in Vol. 23 (1908) of the Architectural Review two excellent papers by Mr. Dunn, which will afford him considerable information on the graphic solution of dome stresses.

PERCY J. WALDRAM.

Plague of Snails and Slugs.

HALIFAX.—PUZZLED writes: "Can any cure be recommended for a pest of snails and slugs inside a dwelling-house? Great care has been used in examining walls and having holes pointed, but still they infest the house, both cellars and ground floor. The house is an end one in a block of five, and the gable abuts upon a field, but without opening on that side."

Having dealt with a similar difficulty, we should imagine that the soil under the house is perpetually damp. In the case in question the house, a small, speculative built one, was one in a terrace, and situated half-way up a slight slope, and without cellars. Very little trouble had been taken in levelling the ground at the front and back of the house, with the result that the soil was above the dampcourse in places, and at the back the tar-paved yard was above the level of the back sitting-room floor, and out of level, so that pools collected in rainy weather. It was in this room and in the kitchen that slugs were especially troublesome. They also appeared in a cupboard under the stairs, which cupboard opened into the kitchen. A close examination of the floor and skirtings in the back sitting-room failed to reveal any cracks through which the slugs could penetrate. The first thing done was to lower the level of the ground back and front, to put in a land drain to take any ground water from under the yard round the end of the back addition and down the slope. While this was being done local gossip reported that a small pond or dyke had formerly occupied part of the site of these houses, and that it had been filled in when the houses were built. Accordingly, the back sitting-room floor was pulled up, and the soil under was found to be quite moist. A considerable number of large slugs were found. These appeared to have made their exit into the yard, through an airbrick which was below the yard level, and up a crack between the tar paving and the wall. Their entrance into the back sitting-room was up a small crevice by the grate. The land drain was accordingly continued under the back sitting-room. The soil under this room was then covered with 4ins. of concrete graded to an outlet through the wall into the yard. The yard was then relaid in Portland cement concrete, graded to fall away from the house, a gutter was formed along the fence to take the water which during rain usually poured in from the next yard above, and a gulley put in to take the yard water. A cement plinth was also put up round the back addition, and under the back sitting-room window. It is needless to say that these radical measures were only taken after all other means had failed, and they have proved quite effectual. We fear if the soil under or round the house is perpetually damp, nothing short of eliminating the dampness will be satisfactory. Perhaps this experience may suggest something to our correspondent; or, if readers have any other remedies we shall be pleased to give publicity to them.

Our Plate.

Suggestion for the Development of the George's Dock Site, Liverpool.

The drawing shows an endeavour to provide a worthy architectural group of buildings and a satisfactory setting for these by so arranging the approaches to the landing-stage, etc., that a harmonious composition may be the result. The main part of the scheme shows a large building between the new offices of the Mersey Dock and Harbour Board and those of the Royal Liver Friendly Society, at present being erected, and the chief difficulty in designing this centre block was to harmonize and in no way detract from both these fine buildings.

This has been done by having a lower building in the front, forming a link between the two higher blocks, all grouping together and leading up to the highest building in the rear, which would be over 300ft. in height, dominating the whole group without in any way dwarfing them, and forming a magnificent landmark at this unique position. The lower building has been planned for a large public company, shipping offices, or exchange, and the great depth of the old dock has been utilised by arranging for a complete bathing establishment arranged on the most modern and luxurious lines, with large swimming bath lined with marble, and Turkish, electric, and other baths. The higher building in the rear is planned as a modern hotel, completely provided with all the modern requirements for a great caravanserai to meet the wants of the Transatlantic and other passenger continually arriving at the adjacent landing stage. On the roof, commanding a magnificent view over an open air café chantant, salle de fêtes, restaurant, etc., are arranged, with express lifts from the basement. Moving stairways and luggage lifts are arranged from the landing stage, the luggage to the hotel running directly through tubes from the stage to the hotel basement. Along the river front, above the great floating landing stage, a colonnaded promenade is designed to form a magnificent standpoint from which to see the great shipping activity of the city, and the unbroken line of the parapets and colonnade forming a fine base to the buildings in the rear when seen from the river.

Underneath this promenade would be found ample space for parcel offices, waiting- rooms, restaurants, etc. At the near or northern end an arch is thrown over the floating gangway, under which would pass the enormous traffic through this artery of Liverpool. The space in front of the building is planned with ornamental grounds, groups of statuary, etc. The designers of this scheme are Messrs. J. M. Porter and Elcock, of Colwyn Bay, and their idea seems well worthy of the consideration of the Liverpool authorities.

House at Thames Ditton.

This house is being built at Thames Ditton for A. Jacob, Esq., and is now nearing completion. It stands on a beautiful site overlooking the River Thames and Home Park, and forms part of the old pleasure garden to the historical house of Boyle Farm. It is entirely built of local red sand-faced bricks, and is roofed with dark, hand-made tiles of varying colour. Leaded lights and iron casements are used throughout in heavy wood frames. The billiard-room and music-room are two large rooms, which can be thrown into one by means of sliding doors, and a feature is made of the hall and staircase, which is in oak and heavily beamed, the ingle fireplace here being in small dutch bricks and tiles, surmounted by an oak beam and a deeply-carved panel, with figures in full relief. The principal rooms overlook the river, and the dining-room and hall open on to a verandah. A motor-house is attached, designed in harmony with the house. The architect is Mr. A. Jessop Hardwick, F.R.I.B.A., of Eagle Chambers, Kingston-on-Thames, and the contractor, Mr. E. Potterton, of East Molesey. Casements and leaded lights are by Messrs. Geo. Wragge, Ltd., of London and Salford, and internal fittings are by Messrs. Thos. Brawn, and Co.

In Parliament.

By our Gallery Representative.

Ancient Monuments in Ireland.

Mr. Ginnell asked the Chief Secretary for Ireland if he would ask the Estates Commissioners to instruct their inspectors not to wantonly lay down any line of fence or road so as to mutilate or destroy any rath or any other ancient monument, historic or prehistoric, whether registered or not.

The Attorney-General for Ireland (Mr. Cherry) said the Estates Commissioners and their inspectors were fully alive to the importance of preserving ancient monuments. The Commissioners did not consider that there was any necessity for the issue of instructions such as were suggested in the question.

Duke of York's School.

Mr. Haldane, the Secretary of State for War, has informed Mr. Hart-Davies that no decision has yet been come to as to the future of the Chelsea site of the Duke of York's School.

Victoria and Albert Museum.

Mr. Harcourt stated in answer to another question by Mr. George Gibbs that the total cost of the erection of the Victoria and Albert Museum, the funds for which were provided by the Public Buildings Expenses Act amounted up to 31st March last to £512,228, of which £194,488 represented the payments during the past three financial years. On furniture and equipment the sum spent in the same period was £2,533. Considerable sums were yet due to the contractors especially in connection with furnishing.

Societies and Institutions.

The Concrete Institute.

The Concrete Institute, of which the Earl of Plymouth, C.B., is President, and which has now over 750 members, celebrated its first anniversary on Thursday, July 22nd, by a visit to one of the largest Portland cement works in Europe, i.e., the Swanscombe branch of the Associated Portland Cement Manufacturers, Ltd., near Gravesend, better known as the J. B. White Bros' branch. About 100 members of the Institute attended this visit, and among the party were Mr. Edwin O. Sachs, F.R.S.Ed. (chairman), Mr. E. P. Wells, J.P. (hon. treasurer), Mr. C. H. Colson, M.Inst.C.E. (Admiralty), Mr. W T. Hatch, M.Inst.C.E. (Met. Asylums Board), Mr. W. G. Kirkcaldy, Assoc.M.Inst.C.E., and Mr. George Corderoy, F.S.I. The visitors were met at Cannon Street Station at 10.30 a.m. by the Chairman of the Associated Portland Cement Manufacturers, Ltd. (Mr. F. A. White), and by Mr. H. H. D. Anderson, Mr. Herbert Brooks, J.P., Mr. H. K. G. Bamber, F.C.S., Mr. Alfred Stevens and other directors, and were taken in saloon carriages to Northfleet, where they were entertained to luncheon at the Factory Club. They were then driven by special trams to the Swanscombe Works, which contain the largest installation of rotary kilns in this hemisphere. The output by this plant alone

exceeds 600,000 tons per annum. The visitors went over the works in eight groups, each group being under a technical guide and a director of the company, and so a most thorough and instructive inspection was insured. Afterwards the visitors were entertained to tea, and they reached London again by 7 p.m. Mr. White, in welcoming the party, dwelt on the rapid development of the Concrete Institute into one of the most important institutions. Mr. Sachs in his reply commented on the broadminded policy of the company in including in their invitation such members of the Institute as happen to be directors or chemists to competing cement works. This policy, he pointed out, made for a greater efficiency in the whole of the nation's Portland cement output, a factor of importance in such a great industry as that of the Portland cement trade. He also remarked on the danger resultant from the keen competition in the selling price of Portland cement, as the building owner really buys the material almost at cost price (few indeed of the cement makers paying anything more than an interest on their preference capital, if as much as that). The rivalry of cheapness allows large manufacturers to keep up their quality, but makes it extremely difficult for the small manufacturer to follow suit. As a matter of fact, he considered the price of Portland cement unnecessarily cheap. There was no reason why the price should not be a little higher, for one shilling per ton made but an infinitesimal difference in the cost of a £25,000 building. Among others who spoke on the occasion to thank the hosts for their reception were Mr. C. H. Colson, M.Inst.C.E. (Admiralty), and Mr. Munro (Stuart's Granolithic Co.), and among those who replied for the directors were Mr. Bamber, F.C.S.

Royal Sanitary Institute.

The Royal Sanitary Institute have appointed Prof. Henry Adams, M.Inst.C.E., F.S.I., Dr. Louis C. Parkes, M.D., D.P.H., Prof. W. Napier Shaw, D.Sc., M.A., F.R.S., and Mr. A. Saxon Snell, F.R.I.B.A., as the adjudicators for the next "Henry Saxon Snell Prize" Competition, the subject set being: "The Principles of Heating and Ventilating Public Buildings." The essays have to be delivered at the Institute, 90, Buckingham Palace Road, by the 31st August.

R.I.B.A.

The results of the summer examinations have now been declared. The preliminary examination for probationers resulted in 156 candidates being admitted of whom 52 were exempted candidates. For the intermediate examination qualifying for registration as student, 144 candidates were examined and 65 passed, three others being exempted from this examination. For the final and special, qualifying for candidature as A.R.I.B.A., 132 candidates were examined and the following passed: P. T. Adams, London, W.C.; H. C. Anderson, Heywood, Lancs.; Wm. C. Autcliffe, Fulham; B. V. Bartholomew, Walthamstow; W. Bell, Dundee; A. Binning, Blackheath; H. Boddington, jun., London, S.W.; A. H. Boss, Victoria Park; F. H. Brazier, Hale; C. Bristow, West Norwood; W. J. Brough, Finsbury Park; P. Caminesky, Maidenhead; H. Carnelley, Hampstead; C. D. Carus-Wilson, Sevenoaks; W. D. Cathcart, London, W.; G. S. Cockrill, Gorleston; H. C. Constantine, London, W.C.; V. C. Cook, Wolverhampton; C. R. Corfield, Edgbaston; J. L. P. Dahl, South Hampstead; W. F. Dickinson, London, S.W.; E. J. Dod, Liverpool; A. L. Edwards, Wimbledon; A. N. Edwards, Leicester; J. S. Ferrier, Edinburgh; G. E. Fitzgerald, Bedford Park; H. S. Fleming, Erith; *C. A. Geen, Lewisham; R. F. Gutteridge, Southampton; F. W. Hagell, Whitehall Park; D. Harvey, Hull; A. G. Henderson, Glasgow; R. Hotz, Wandsworth Common; J. W. Jarvis, Harrow; J. M. Jenkinson, Sheffield; W. Kanla, Earls Court; *H. Kenchington, London, W.C.; W. H. Ludlow, Clapham Common; *T. Y. Lusk, London, N.; A. J. C. McLean, Brighton; C. S. Madeley, Birmingham; *J. T. Mair, Wellington, N.Z.; F. J. M. Maxwell, Bedford Park; W. L. Mellor, Manchester; C. B. Metcalf, Bradford; *G. A. Mitchell, Acton; H. W. Mole, Newcastle-on-Tyne; E. E. Morgan, Crouch End; *H. S. Morris, London, S.W.; *R. H. Nicholson, Sunderland; R. Orr, Poole; E. S. Petch, Scarborough; H. M. Pett, Brighton; R. Pett, London, W.; W. S. Purchon, Sheffield; S. H. Rainforth, Ravenscourt Park; C. H. Rose, Wimbledon; H. A. Ross, Shepherd's Bush; H. S. Sawyer, Bromley, Kent; H. E. Seccombe, Weybridge; J. Seddon, London, W.C.; H. P. Shapland, Canonbury; C. H. Simpson, Putney; *F. R. Smith, Acton; D. W. Stewart, Tottenham; W. W. Tasker, Jesmond; A. Turnbull, Sunderland; H. Unwin, Wigan; G. Vey, jun., Chiswick; *H. Waler, London, W.C.; H. G. Warlow, Sheffield; J. D. D. Watt, Falkirk; G. H. Williams, Windsor; J. B. Wills, Highbury; G. C. Wingrove, Newcastle-on-Tyne; J. G. Young, Alloa.

(* Special Examination.)

The Institution of Municipal Engineers.—Annual General Meeting.

The first annual general meeting of the institution, of which Mr. John T. Pegge, city engineer and surveyor of Durham, is president, will be held at the Town Hall, Durham, on Saturday, August 7, 1909. The official programme is as follows:—At 11 a.m., the members will be received at the Town Hall by His Worship the Mayor of Durham (J. T. Boyd, Esq.). Presentation of annual report of the Council. 12 a.m.: Discussion of paper, "The Design and Requirements of Electric Power Works," by Horace Boot, M.I.E.E., A.M.I.Mech.E., which was presented at the general meeting held at Olympia on April 24th last. 1 p.m.: Lunch. 2 p.m.: Paper, "Municipal History and Works of a Small City," by the President of the Institution, followed by discussion. 3 p.m.: Paper, "The Durham Main Sewerage Works," by Harry W. Taylor, Assoc. M.Inst.C.E., of Messrs. Taylor, Wallin and Taylor, consulting engineers to the scheme. 4.30 p.m.: Visit to Durham Castle and Cathedral. At the conclusion of the meeting the result of the ballot for election of the Council for the year 1909-10 will be announced.

At a meeting of the Bolton Board of Guardians on the 21st ultimo, it was stated that letters had been received regarding the fair wages clause, and firms whose tenders had been accepted by the Board for work at the workhouse. The clerk explained that the letters were from the Bolton branches of the National Amalgamated Furnishing Trades' Association, and the National Amalgamated Society of Operative House and Ship Painters and Decorators. Both letters stated that the fair wages clause had been violated by certain firms. The second-named society complained that the firm they wrote about were not on the recognised "fair list," and the majority of the men employed were brought from other towns. That debarred local painters from getting a share of work, which in the society's opinion should be done by local men. They requested the tenders to be reconsidered.—Ald. Haslam said the question was not as to what the societies recognised, but whether the firms were paying the standard rate of wages.—The clerk pointed out that the attention of the two firms was drawn to the clause, and both agreed to it before signing.—After further discussion the clerk said he had drafted two letters which, with the permission of the board, he read. These stated that the firms entered into the contract making it a "condition that they pay all workpeople in their employ the regular standard rate of wages as recognised by the various trade unions and employers' associations." The letters asked, in conclusion, that the two complaining societies state in what particulars, and how, the fair wages clause had been violated. It was resolved that the letters be sent to each of the societies.

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Aug. 30	FOREST HALL, Elementary school for 250 scholars. County of Northumberland Education Committee invite designs from architects practising in the County and in the City and County of Newcastle-on-Tyne. Particulars, conditions and plan of site from C. Williams, Secretary to the Education Committee, The Moot-hall, Newcastle-on-Tyne.
Aug. 31	HUDDERSFIELD NEW CHURCH. Plans are invited for a church to seat 400, to cost about £2,000, not to exceed £2,500, with all fittings, furnishings, lighting and heating apparatus. Plans to be forwarded to the Rev. D. Macræ Tod, B.D., St. James' Manse, Huddersfield, by Aug. 31.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.
Sept. 20	HULL TRAINING COLLEGE for teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.

An important work on cement, its manufacture, testing and uses, by A. C. Davis, F.C.S., Assoc.Inst.C.E., managing-director of the Saxon Portland Cement Co., Ltd., has just been published by Messrs. Woodford Fawcett and Co., 36, 38, Southampton Street, Strand, W.C.

* * *

We have received the "Annuary of the American Institute of Architects for 1909," which gives the lists of officers, committees, Fellows, Associates, etc., of that society.

* * *

Concern has been caused in Enfield by a report of a Local Government Board inspector (Dr. S. W. Wheater), who held an inquiry into matters affecting the health of the district and the administration of the District Council. He states that the condition of a large proportion of the older houses illustrates the evil results of uncontrolled speculative building. Hundreds of houses are composed of sandy bricks, which are crumbling away, and absorb and hold the damp and moisture. Damp-courses are either absent altogether or too low to prevent dampness of the walls. Roofs are improperly laid, and air space and lighting are inefficient and defective. The report contains many other severe criticisms concerning sanitary and hygenic conditions.

BRITISH FIRE PREVENTION COMMITTEE.

The British Fire Prevention Committee concluded its summer session with two series of testing operations, one relating to the all-important subject of the possibility of making flannelette permanently non-inflammable, and the other relating to types of chemical fire extinguishers in which the necessary force is obtainable by the external application of small chemical charges easily open to inspection. The tests were conducted in accordance with the usual procedure of the British Fire Prevention Committee and the members were received by Mr. Edwin O. Sachs, F.R.S.Ed., (chairman), Sir James Williamson, C.B., Mr. W. T. Hatch, M.Inst.C.E., and other members of Council, and there were present among others Lord Londesborough (president of the Firemen's Widows' and Orphans' Fund); Sir Horatio H. Shephard, M.A., LL.D.; Mr. J. F. Moylan (Home Office); Mr. Ollis (Chief Officer Public Control Department of the L.C.C.); Mr. S. Gamble, F.S.I., Lieutenant Sladen, R.N., Mr. Dyer, of the London Fire Brigade, and a number of officials from the various Government and Municipal Departments concerned. The tests with the extinguishers were conducted by a sub-committee, of which Mr. Percy Collins, J.P., was the directing member. The flannelette tests were conducted by a sub-committee, of which Mr. Ellis Marsland (district Surveyor) was the directing member. Among the members of the sub-committee assisting were Mr. J. Herbert Dyer and Mr. Horace Folker (vice-presidents of the National Fire Brigades' Union), Mr. E. J. A. Fulkes and Mr. Bertram Chatterton (insurance surveyors). The flannelette tests were a series dealing with 150 different specimens of material of different makes, treated and untreated, and washed and ironed for a varying number of times up to 20 times. The usual official illustrated reports will be issued shortly by the committee dealing with the results of the tests.

Fire Prevention Notes.

Tests of Fireproof Doors. The tests held on February 24th last by the British Fire Prevention Committee have been officially reported upon as follows:—The object of the test was to record the effect of a fire of four hours' duration at a temperature gradually increasing to about 2,000 F.° (1093.3 C.°), followed by the application of water for five minutes on the fire side with a view of being classified as affording "full protection" (Class B.). Note.—The door openings were to be approximately 3ft. 3ins. wide and 6ft. 9ins. high (.990m. by 2.057m.). The fire was to be applied from one side and the doors were to open inwards on to the fire side. In the case of the "armoured door," the essential requirements of the Fire Offices Committee were to be complied with.

The Armoured Door.

In 34 minutes flame appeared at the top corner of the door on the south side, which gradually increased, until at the end of the test it had spread along the top and down the north side. The door was away from the brickowrk along the top at the conclusion of the test about 1in. (0.25m.). The maximum reading of the hanging thermometer in front of the door was 58° Fahr. (14.4 C.) at 120 minutes and 130° Fahr. (54.4 C.°) at 240 minutes. The paper attached to the post in front of the lower part of the door did not take fire. The effect of the application of water to the inside face of the door was to destroy the external tinned plates on the inside face, and to wash out the wood interior which was carbonised. The outer plates of the door remained in position. Both fire and water passed through the door. Classification was not obtained.

The Iron Door.

In five minutes the door was too hot to hold the hand over. The radiated heat increased so that in 80 minutes the paper on the post in front of the lower part of the door took fire. The maximum reading of the hanging thermometer in front of the door was 220° Fahr. (104.4 C.) at 120 minutes, and 180° Fahr. (103.3 C.) at 240 minutes. In 152 minutes the door was at a dull red heat all over. At the conclusion of the test it was at a bright red heat in all but the lower 18ins. (.457m.). The door bulged inwards during the test about 1in. (.025m.), and on the application of water the bulging increased. Flame did not pass through the door, or between the door and frame. Some water passed through the space between the door and frame where buckled. Classification was not obtained.

"Checkfire" Doors.

The objects of the test were here the same, but the door openings were to be approximately 2ft. 9ins. wide and 6ft. 5ins. high (.838m. by 1.956m.).

Door A.

In 80 minutes the top north corner of door commenced to buckle inwards and continued to do so till the end of the test, when a maximum of 1½ins. (.038m.) was recorded. Buckling also occurred down the north and south sides during the test. In 164 minutes flame appeared over top of door at north corner. In 215 minutes flame appeared through edge of door on south side between lock and sill. The maximum reading of the hanging thermometer in front of the door did not exceed 80° Fahr. (26.6C.). The paper attached to the post in front of the lower part of the door did not take fire. Water passed between door and frame. Classification was not obtained.

Door B.

In 110 minutes the bottom and top corners of the door on the north side buckled outwards, the maximum at the top after 215 minutes being 1⅛ins. (.28m.). In 210 minutes flame came over the top corner of door on the north side, and in 234 minutes flame appeared below the lock between the edge of door and brickwork. The maximum reading of the hanging thermometer in front of the door did not exceed 72° Fahr. (22.2C.), The paper attached to the post in front of the lower part of door did not take fire. On water being applied to the inner face of the door, the door contracted almost to its original position in the rebate, and buckling mentioned above was not visible. Water passed freely over top and under bottom of door. Classification was not obtained.

The "Checkfire" Door Co. point out that it is seen from this report that their doors have thus established a record for fire resistance, the weaker of the two being fourteen minutes better than the previous best recorded time.

Fireproof Construction Needed. In a recent issue "The North American Review" published a strong plea for fireproof construction in an able article by Mr. Louis Windmuller. The author points out the almost criminal disregard by Americans of the precautions adopted in other countries, a carelessness resulting in an annual loss of a quarter of a million dollars through fire. "Dangers Lurking in Woodpiles," is the title of the article, and that many of our structures are merely woodpiles is shown by the conflagrations that occur. On the subject of fireproofing construction, Mr. Windmuller comments in part as follows:—"When we turn to large buildings in large cities we find many skyscrapers from fifteen to twenty-five stories high, which consist of steel frames filled with concrete, and covered by an outside curtain of stone; they are erected in the most approved manner within twelve months from the laying of their corner-stones. This celerity is accomplished by means of three shifts of skilful workmen, who constantly labour with the utmost zeal and the best implements—during the night by artificial light—to make the timely surrender feasible. Contractors who complete the work earlier than agreed upon receive a premium; while those who remain in arrears are fined for every day's delay. Although the erection of these structures is pushed on with a rapidity repugnant to the mind of the old-school of architects, they have successfully withstood every attack of the fiery elements; in cases where their contents have been cremated their presence became a bar to the progress of a conflagration. A building of this class, which was constructed under such conditions as I have described, survived the Baltimore ordeal of February, 1904. When older structures had to succumb, at least two of these structures bore the test of both flames and earthquake in San Francisco in 1906. It is confidently expected that if not all, almost all, will be found equally staunch during any future conflagration, even though a proper inspection during their construction may be impossible. In reconstructing Messina in Sicily, which was recently destroyed by an earthquake, several large buildings of steel construction are being erected." In hardness and durability concrete equals if it does not surpass the best stone. When timber became scarce it was used as a substitute by the ancient Greeks and Romans. The continued existence of the ruins of their concrete temples erected several thousand years ago proves the strength of the substance. The supply of good cement and of concrete is inexhaustible. Large buildings have been erected of it in many cities and in some suburbs at a lower cost than that of other material which could have been obtained for them. This is especially true of the Pacific coast. Some of the finest villas were built of concrete in Buenos Ayres in Argentina. Concrete is supposed to be proof against moderate earthquakes. A great part of San Francisco has been rebuilt of reinforced concrete. Pretentious but combustible bungalows should be replaced by comfortable dwellings which will be as impervious to fire as to water, and which will not be, like the old frame houses, in need of constant repairs.

REINFORCED CONCRETE AS A FIREPROOF BUILDING MATERIAL.

In the last few years reinforced concrete has come into such prominence as a building material that it is attracting the attention of all who are in any way interested in building, both the owner, architect, engineer, and insurance companies. They are asking many questions, and it is the endeavour of this paper to answer a few of them, although in so doing some points will probably be covered which are already pretty well known to the insurance interests, but it is necessary to mention them in connection with a more careful study of other features which are of such recent development as to be less known at present. The writer will first endeavour to explain some of the recent developments in building construction in this material, but as "recent" is a relative term, it is first necessary to explain what are now considered obsolete methods.

From the earliest use of this material, reinforcement, chiefly in the form of bars of various sections, were embedded in the concrete to take up direct tension only, concrete being required to take care of compressive stress as well as shearing stresses, both vertical and diagonal. The arrangement of beams, girders, and panel has changed but little, and has followed closely the arrangement common in wood and steel construction, the essential difference being in the present use of the reinforcement. Fifteen years and more ago a beam or girder was reinforced with straight bars embedded near the bottom of the member and extending but a short distance over the supports. There were no bent-up bars and no stirrups and no steel in the top of the member over the support. Such beams carried very heavy loads and are still doing good service. Some few which were overloaded showed cracks, and these, together with the cracks which have developed in a similar way in test specimens, have furnished the data for the more recent arrangement of the reinforcing metal. The next step in advance was the use of stirrups, set either vertically or at an angle, embedded in the beams, and their ends projecting a short distance into the panel. These were embedded near the ends of the beams or girders. A little later, in addition to these stirrups, some of the main bars were bent diagonally upwards at an angle of about 45 degrees from about the quarter point of the span, and then were carried across the top of the beam at the support and for some little distance into the adjoining span. These tied the beams together across the support and formed continuous beams, thus increasing their strength for a given weight of metal as compared with the same weight of straight bars at the bottom only, besides tieing the building more thoroughly together.

The latest development which has not as yet come into general use, but which ought to be encouraged, is of tieing all the reinforcement rigidly together that goes into a beam or girder and so fastening it into place in the forms that it cannot possibly be moved while the concrete is being placed. When bars were placed loosely it was an easy matter to displace them by an inch in height, which makes quite a difference in the strength of the resulting combination, and the ordinary workman or even the foreman does not appreciate how important it is to set the bars exactly right. It adds a little to the expense of the steel reinforcement in place to make up the units and place them rigidly in the forms, but on the other hand it saves somewhat in the placing of concrete so that the resultant extra cost is comparatively small and is entirely justified. Years ago claims were made of the advantage of one type of reinforcing bar over another, and also of certain types of mesh reinforcement in the panel were claimed to be much better than others, with the result that when interested parties made their designs, the amount of metal used was not based so much upon engineering principles as upon the commercial point of selling, and it was not uncommon to have the reinforcement stressed to nearly its elastic limit, and the structure therefore had a very small factor of safety. To-day it is well recognised that a sufficient area of cross section of metal must be used to keep the working stress within reasonable limits irrespective of the particular type of reinforcement used, and while deformed bars give a better bond than plain bars either squares or rounds, and are therefore to be desired, nevertheless the results obtained with the plain bars are so good that the owner is not justified in price between deformed and plain bars.

The latest development in floor construction, and one which has come to the front very quickly, is the so-called mushroom system of flat floors. These are flat panels without any beams whatsoever supporting them, bearing on enlarged heads on the columns, the reinforcement running directly between columns and also diagonally across the panels. The expense of these floors is no greater than in beam construction in any case, and in many cases it is a little cheaper. The advantage is that head-room can be saved, which reduces the height of columns and walls, making a saving in the building in this way. A flat ceiling is obtained without the expense of a false flat ceiling, and from a fire protection standpoint it is desirable because it is so much easier to throw a stream of water to any part of a large room without danger of its hitting a beam or girder and being deflected to the floor before reaching the farthest limit a horizontal stream can be thrown. Also in this ceiling there are no pockets to hold heated air which cannot circulate and therefore transmit heat through to the floor above, as exists in exposed panel construction with ordinary beam and girder floors. This type of floor can be used on spans as great as are ordinarily used in beam construction. The writer has built floors for 125lbs. live load per square foot on spans 20ft. by 23ft. to centres of columns, using a slab 7ins. in thickness. He has also used a slab 10ins. thick on spans 24ft. each way, with a live loads of 250lbs. per square foot. The panel should be approximately square. If one dimension is more than 20 per cent. greater than the other, economy ceases in this type of construction, and it is then preferable to use beams with a panel between reinforced in one direction only.

Numerous fire tests have been made to determine both the resistance of concrete to actual test, and also the depth to which the reinforcement must be imbedded to prevent its being damaged. The maximum depth of pitting observed by the writer in actual fire tests where a temperature of 1,700 degrees F. or more has been maintained for a period of five hours, has been in either walls or ceilings one inch to one and one-half inches. Also, by the examination of actual conflagrations, such as that at Baltimore, and elsewhere, it has been apparent that the prearranged fire tests are more severe in the results shown by the structure than actual conflagrations. Therefore, if we can protect the materials against damage in a prearranged test, they will stand any actual service. The consensus of opinion of engineers is that there should be at least one inch of concrete between the nearest point of a bar to the ceiling in panels, at least two inches below the ceiling in beams and girders, and also two inches of concrete outside the vertical bars in columns. In designing columns it is common to figure only that area of column inside the vertical bars when hooped as carrying the load, or if hoops are omitted and but light reinforcement is used to prevent bending stresses, to add an extra inch beyond that needed to carry the load all round the outside, which might be burned away without endangering the load-carrying capacity of the balance of the column within. If this is burned off it can be plastered back, giving the column the same fire-resisting qualities as before.

Fire underwriters are always interested in knowing whether a particular structure is properly built or not. There is very little difference in outward appearance between one of perfect construction, that is, in regard to size and placing of steel, size of members, etc., and one which is imperfect, and the only positively sure way to know is either by inspection or by test. There is no type of construction where more painstaking care in providing for every detail is necessary than in reinforced concrete. Concrete is either good or bad. There is no half-way about it, and if bad effects are manifested before the builder is clear of his work, he is usually the one to suffer. When possible, limit the competition to reputable builders of experience, who have demonstrated their ability to erect the work in hand and who are known to do always good work. If this is not practicable then the work should be inspected as it goes along. A precaution to assist inspection as previously stated is the setting of the steel rigidly in place before pouring the concrete. The quality of the sand and stone used must be as carefully inspected as the cement, and a sufficiently rich mixture required to allow for inequalities of mixing and placing. With well graded materials, and first-class workmanship a floor can safely be built with a mixture of one cement, three sand, and six stone, and as insurance against uneven or poor workmanship to-day it is quite common to specify a mixture of one, two, four, which, with thoroughly first-class workmanship, gives a stronger result than is necessary, and with ordinary or careless workmanship ought to give a job which is still strong enough. Incidental to the process of construction, while the concrete is still green and much weaker than it will be with age, it is loaded frequently as heavily as it ever will be in actual service, and always it is loaded sufficiently to give a fair idea of its strength. Where there is any doubt of its strength, load tests can be applied. With these safeguards, in addition to those provided by the engineer, architect, or building department, the underwriters need have no fear that a building they are asked to insure is structurally weak.

The question is sometimes asked, what proportion of builders now engaged in reinforced concrete work are competent? It is impossible for one who has no wide acquaintance with builders in all parts of the country to answer such a question. He can simply say that in all large cities there are a few builders whose ability has been proved beyond a doubt, and the selection of any one of them is insurance that good work will be done, and by the competition between them reasonable prices can be obtained.

The other types of fireproof construction which are coming into competition with reinforced concrete are structural steel encased in concrete, and this, when thoroughly encased from a fireproof standpoint is similar to an all-concrete building; structural steel frame encased in terra cotta, and to a small extent plaster of paris and brick have been used in fireproofing steel, but not to a sufficient extent to be worthy of much comment. Thoroughly well-laid brickwork is a good protection to columns, but when cast as arches between beams it leaves the bottom flange exposed, which is a serious defect. Actual conflagrations have conclusively shown that terra cotta is not so perfect a fire protection as concrete. This is largely, in the writer's opinion, due to the fact that its coefficiency of expansion is high, so that it expands to such an extent that when confined between the beams it is crushed, the lower member falling, and thus weakening the floor. It is also more susceptible to a combination of fire and water, being to some extent brittle and cracking when a cold stream strikes a hot surface.

Before concrete will disintegrate when exposed to fire, the large amount of moisture chemically combined in the setting of the cement, being 20 per cent. or 25 per cent. of its weight, has to be driven off by heat, and then the vapour thus driven off has to be evaporated from the pores of the concrete before it becomes sufficiently hot to crumble. The slowness of evaporating this vapour is probably the cause of concrete resisting extremely high temperatures for the brief period of a few hours, while a much lower temperature, if long continued, would ultimately disintegrate it. Cement will resist 500 degrees F. for an indefinite period, while a continuous temperature of over 700 degress F. is disastrous. The cement coating of the stones of the concrete will resist the attack of fire so long that it is of less consequence whether the stone can be damaged by the fire or not. Thus pure limestone is a most excellent aggregate, and will not decompose until after the cement has, and after the cement has gone it is immaterial what aggregate is used, as the work has then failed anyway.

Regarding the cost of this type of construction as compared with others, the large use has proved conclusively that it will compete, because the item of cost is considered paramount in 99 out of every 100 structures. For large buildings the structural frame is almost always cheaper than the steel. Thin curtain walls cannot be built as cheaply on account of form work, which is constant for a thin wall as well as for a thick one, but if the wall must be sixteen inches or more in thickness, concrete is cheaper than brick. In small structures, such as dwelling-houses, concrete is materially more expensive than brick or wood, because the form work is more irregular, cannot be used over, and because of the greater expense of supervision. This is why it is not commonly used in small dwellings, and probably will never be much used. It has been used and can be economically used for large dwelling-houses, especially those of simple design, where the form work is nearly as easy of execution as in an office building or mill.

It has been decided to rebuild the Bradford Infirmary on a central site, which is now under consideration.

PREVENTION OF STEAM IN DYE WORKS.

A correspondent having raised a point about superfluous steam in a vat-room it may be assumed that the steam of which he complains is caused and made a nuisance by the cold air that is let into the shed "to blow the steam away," and by the coldness of the walls and roof chilling the vapour to a temperature near the dew point. The only ways to prevent this are to keep the room or shed warm, and to warm the air as it enters. This is best done by a fan blowing in hot air from the engine or boiler house, or from an air heater in the chimney flue, this last being the cheapest method. To enable the steam to get away from the vats and pans, and to prevent its spreading all over the shed—and the latter is the chief trouble—a hood is needed to each vessel, with a chimney or two, according to size. These chimneys are best made of wood, plumb all the way up, and with boards inside as well as out to keep the steam above the condensing point in winter. When these chimneys or towers are open at the top, or fitted with a lid as shown in Fig. 1, or else pivoted at the centre, the net area of the tower should be not less than one-sixth that of the surface from which the steam comes; with a closed top or partly-closed top and louvred sides, as shown in Fig. 2, the area should be not less than one-fourth that of the surface from which the steam comes. It is likely that our correspondent will have to use tops and louvres, as the uneven height of the buildings around will cause eddies and down-blast when the wind is from a direction different from that shown. Canvas curtains or light, wooden shutters, with cords and balance weights, may be needed by some machines at the hoods, and if light on to the beck or vat is needed, the slope of the hood can be of glass. The towers for loose steam are not boarded below the roof, while those for the becks are, of course, boarded down to the hoods. Towers from the becks mean that the roof details cannot be settled till the position of the becks are known, which is as it should be, for a dye-house is a huge machine, and no one part can be skilfully decided on without consideration of the others. Open slates are all right on the roof in summer, but of great harm in winter; for a warm roof is needed to prevent drip and the chill of winter winds blowing between the slates at once takes out any warmth they may get from steam. It is the drip on to finished cloth that spoils it, and enquirers will have found that dyers will endure steam, but will not have drip. Can the fans of the adjoining mill not blow into the dye-house? They may not supply enough warmth and air, but they can clear steam from their own region. If the vats can be raised high enough to allow the spent liquid from them to go through 4in. hot-water pipes along the house to the drains, a good deal of warmth will be given to the house every time a vat is run off, and at no cost in fuel, and with a saving in steaminess compared with the style of emptying the vats on to the cement floor. A warm dye-house is a clear one, and a cold house a steamy one. Exhaust steam may be available, and can be used in pipes slung overhead, and if used to warm the entering air it can be condensed quickly in winter, thus saving water. Superheated steam in pipes overhead will give warmth at no extra cost above that for ordinary steam to boil only. A tubular air-heater for steam or to burn coke could be fixed on the north-western wall, and whenever the prevailing wind blows, volumes of warmed air will get into the dye-house without help from a fan, and the house would be warmer and drier. The cost of this heater, fixed, may be £100. With a steam chimney direct to each vat, much smaller outlets are needed at the ridge, and the writer has never yet come across a louvred ridge that was satisfactory and could be relied on. Pivoted louvres are always an aid, and will probably cost less than the wind-screen our querist suggests. There is no need to use a steam pipe in the chimney to make draught; the vat sides warm enough air to make a current, and the space between the double boards keep in the heat. To our best knowledge, pitch-pine straight from the saw, unplaned and unpainted, is good timber for the main rafters. Elm will be good for the lining boards of the steam chimneys. The wind screen described by the enquirer will not help the ventilator, and the timber it needs would be better used to cover the lower portion of the louvres, thus raising them higher above the roof, and obtaining a chimney-like action on the steam and air. It is the way to get air and warmth into the shed that is more trouble than getting the steam out. The greater steaminess in summer will be due to eddies and draughts on the roof, making a balance of air pressure, and preventing movement being given by the wind to the air in the shed.

THE LONDON FIRE BRIGADE

The London County Council has in contemplation or in hand sundry alterations and improvements to fire stations:—

Clerkenwell Fire Station.

This station is to be altered and enlarged, at a cost estimated at about £11,000 to £13,000. Room for the extensions will be obtained by the acquisition of No. 42, Rosebery Avenue, at a cost of £1,350. By this rearrangement it will be possible for the horses to be stalled behind the appliances, for all the single firemen to be accommodated together on the first floor, with sliding poles to the ground floor, for up-to-date quarters for married men to be provided on the upper floors of the extension, better accommodation for the long ladder, a covered run-in for the appliances, a separate entrance controlled from the watch-room, and a drill tower.

Woolwich Fire Station.

Tenders are to be invited from selected firms during the present recess for the alteration and enlargement of this station.

New Station, Bromley-by-Bow.

A new fire-station is to be built in Brunswick Road on a piece of vacant land acquired by the Council, and quantities are to be taken out and lithographed with a view to inviting tenders for the erection of the building.

Inspection Work.

The work performed by the inspection branch of the fire brigade, and consisting principally of the inspection of theatres, music halls and other places of public entertainment, common lodging houses, and Government buildings, and of work arising out of applications under the London Building Acts, has during the past few years greatly increased, the increase being most marked in the number of inspections made of buildings in which cinematograph entertainments are given, and in the number of reports on applications for consent to the erection of buildings of large cubical extent. The number of these applications has grown substantially since the clauses in the Council's General Powers Act of 1908 on the subject became law, and a recent decision of the Building Act Committee that those buildings of large cubical extent in which fire-appliances are required to be provided as a condition of the Council's consent should in future be annually inspected by the brigade also increases the work of the inspection branch. The brigade inspection staff consists at present, apart from technical and clerical assistants, etc., of a superintendent, two district officers, and six station officers, a total of nine men, and it has stood at this number since 1904. In May, 1906, however, the number of station officers engaged on the inspection of theatres, etc., and common lodging houses was reduced by one, and in place of this station officer a district officer was appointed for work in connection with the inspection of Government buildings and the preparation of reports on Building Act applications. The reduction in the number of men required for the inspection of theatres etc., and common lodging houses was made possible by the fact that the first inspections of all common lodging houses in London were completed in 1906, and that since then annual inspections only have been necessary. The amount of work in connection with these annual inspections of common lodging houses has been fairly constant since 1906, and there is no likelihood of its decreasing. The number of inspections of places of public entertainment has, however, increased by about 7 per cent., and of those at which performances are regularly given and scenery is used by about 9 per cent. Moreover the provisions of the Children Act, 1908, with regard to performances for children, or at which the majority of the persons attending are children, and the number of children exceeds 100, involve additional inspection work.

New Divisional Officer.

Mr. A. R. Dyer, assistant divisional officer has been appointed to the position of divisional officer (North), vacant through the appointment of Lieut. Sladen to the position of chief officer of the brigade.

PRECAUTIONS AGAINST FIRE IN UNDERGROUND ELECTRIC RAILWAYS.

At the last meeting of the London County Council the observations of the Board of trade on the precautions against fire in tube railways, drawn up by the Council, were reported by the Fire Brigade Committee. The resolutions of the Council were as follows:—

(i.) The fire-appliances on all tube railways, whether constructed before or since 1904, should be periodically inspected by the chief officer of the fire brigade with a view to seeing that they are efficiently maintained, and in making such inspection the chief officer should deal with any points which may occur to him affecting the general question of protection from fire, and should communicate direct to the Board of Trade any suggestions which he may desire to make.

(ii.) There should be provided on all tube railways, whether constructed before or since 1904, automatic signal lights, or preferably an illuminated sign, which would show on the platforms of stations concerned and also on the street level when the current to the live rail is cut off in either direction.

(iii.) The owners of all tube railways constructed before 1904 should be called upon to comply, with as little delay as possible, with the requirements made in that year, or if this is considered impracticable, such railways should at least be provided with—(*a*) fire-appliances as far as possible in conformity with the minimum requirements made in 1904; (*b*) a hydrant, with sufficient hose, fitted 100 yards down each tunnel from each end of each platform; and (*c*) an incombustible platform between and at the sides of the rails for persons to walk upon.

(iv.) The minimum requirements, etc., as regards fire-appliances made in November, 1904, should be varied by the omission of the observation (*d*) as to the fire brigade being practically of no avail in the event of a fire obtaining a hold in a tube railway, and the substitution therefore of the following observation—"In the event of a fire in a tube railway not being readily extinguished by the railway employees, notification should be immediately given to the fire brigade by telephone and by the nearest fire-alarm."

The Board of Trade reply on the various points raised is as follows:—

As regards (i.) the Board states that the proposal has been communicated to the companies owning all the tube railways in London, and that these companies acquiesce generally in a periodic inspection of the fire-appliances on their respective lines by a person nominated by the Board of Trade. The Board accordingly asks that the chief officer of the fire brigade may be allowed to make such periodic inspections on their behalf, and the Board suggests that the inspections should, at any rate for the present, be made annually. The Board further suggests that it should be informed by the chief officer when he proposes to inspect the appliances on a railway, and that the Board should then notify the company concerned, leaving the actual date of the inspection to be arranged between the chief officer and the company. Any recommendations or observations which the chief officer may find it necessary to make would be forwarded by him to the Board, and communicated by the Board to the company concerned. There are seven tube railways in London, with about 80 stations, and the inspection would consequently occupy some considerable time, but we are advised that the work could be undertaken by the inspection staff if the Council sanctions the appointment of the additional station officer recommended in the previous paragraph of this report. The order of reference to General Purposes Committee provides that they shall consider and report upon all questions relating to the duties of heads of departments, and we have therefore informed them of the proposal that the chief officer should undertake the periodic inspection of tube railways. The General Purposes Committee concur in the proposal and are submitting the necessary recommendation to the Council accordingly.

With regard to (ii.) the Board states that it is advised that there are objections to the proposal on the grounds both of difficulty and expense. The Board understands that at present there are switches in every signal box or stationmaster's office, whereby the current between any two stations can be cut off, and that firemen could therefore always ascertain by inquiry, or, if necessary, by looking at the switch, whether the current was on or off. In these circumstances the Board did not think it necessary to bring the suggestion to the notice of the railway companies. We pointed out to the Board that the positions of the signal boxes and stationmaster's offices were not exactly known to the fire brigade, and, owing to the small number of officials available at a station, could not always be quickly ascertained; and, further, that in the event of a fire occurring, and the stations becoming heated and filled with smoke, as was the case at the fire which occurred at the Moorgate Street Station of the City and South London Railway on July 16th, 1908, and at other fires, there would probably be considerable difficulty in obtaining access to the boxes or offices in question; and we urged the Board to reconsider the matter and adopt the Council's suggestion. The Board, however, adheres to its opinion that the arrangement proposed by the Council is not reasonably practicable, and in view of this we do not see that the Council can take any further action in the matter.

Suggestion (iii.) deals with tube railways constructed before 1904, when regulations were laid down by the Board, one of which was that efficient hydrants, hose, and fire-appliances should be provided to the satisfaction of the chief officer of the fire brigade. The Board intimates that it brought the Council's recommendation before the owners of lines constructed before 1904, although, as the Board points out, it has no power to impose the regulations of 1904 on the owners of such lines. In reply the owners of the railways affected, viz., the Central London Railway Company and the City and South London Railway Company, have assured the Board that they are desirous of complying as far as possible with the requirements, and the Board understands that work is now in progress on both lines with this object. The inspection to be made by the chief officer will, of course, reveal the progress made with this work, and the chief officer will be able to call the Board's attention to any matters which he considers necessary.

As regards (iv.) the Board states that it sees no objection to the substitution of the words proposed by the Council, and that the railway companies have been communicated with accordingly.

In conjunction with a leading firm of Manchester architects, Messrs. Fryers and Penman, architects, Largs, have secured the work of designing a large and important block of property in Manchester, which is to be utilised for, among other things, an exchange and central agency for the Calico Printers Combine. It is understood that the building may cost from £150,000 to £200,000 before it is completely finished.

* * *

At Edinburgh Dean of Guild Court yesterday, warrants have been granted to the Royal Infirmary of Edinburgh for a new operating theatre; to the Edinburgh Marine Gardens (Limited) for a tea-room; and to John Hay for a tenement at Seafield Road.

Federation News.

The Northern Centre.

The half-yearly meeting of the Northern Centre Executive was held at the Queen's Hotel, Southsea, on Tuesday, July 20th, when Councillor S. Easten, Newcastle-on-Tyne, presided. The chief matter before the meeting was to receive Mr. J. B. Johnson's report regarding the amended N.A.O.P. agreement. Mr. Johnson gave his report, which was considered satisfactory. It was thought that the report would be of interest to all the members, and the secretary was instructed to have the same published in the official journal, and arrangements are being made for it to appear in a later issue. Several matters appearing on the agenda for the National half-yearly meeting were also considered at some length.—JAMES DENVER, secretary.

The Northern Centre Conciliation Board.

A special meeting of the Northern Centre Board was held in Leeds on July 5th, when an appeal was considered from the Rochdale Board re joiners' wages and working rules. The notice was received from the Operatives' Society for an advance in wages of ½d. per hour—9d. to 9½d. Witnesses were heard from both sides, and evidence taken, after which the Board gave the following decision:—"That subject to all present notices for alterations to rules being withdrawn, the wages of the Rochdale joiners be increased ¼d. per hour, such advance to come into operation on July 1st, 1910, and to remain in force for two years from that date." Several alterations were proposed to the remaining rules and adopted. The Rochdale employers agred to withdraw their notice, which had not yet expired; therefore the decision of the Board carries. An appeal from the Blackpool joiners was before the meeting, but owing to the lateness of the hour it was agreed to postpone the hearing of same until the 28th ult.—JAMES DENVER, Employers' Secretary.

Yorkshire Federation.

The monthly meeting of the Executive Council of Yorkshire Federation was held at the Albemarle Hotel, Westborough, Scarborough, on Friday, July 16th. Mr. W. R. Thompson (president) was in the chair, and 31 delegates were present from affiliated associations. The receipt of £32 13s. 4d. from various sources during the month was duly reported. It was reported that quotations had been received for the insurance of horses belonging to the members for either trade or private purposes. On the motion of Councillor W. G. England, J.P., seconded by Alderman J. Birch, J.P., the quotations were referred to the Emergency Committee for consideration and report.

The observations of the Grimsby, Leeds, Sheffield and Wakefield associations were reported on the draft sub-contract form submitted for consideration. On the motion of Councillor W. G. England, J.P., seconded by Mr. T. Lindley, it was resolved to afford local associations a further opportunity of giving the draft agreement their careful consideration, with a request for observations to be submitted in writing not later than September 1st.

Mr. T. Lindley, the president of the N.A.M.P., explained the draft proposed revised agreement with the N.A.O.P. The Federation, on the motion of Mr. T. Lindley, seconded by Councillor J. Dawson, approved of the revised agreement between the National Federation, the National Association of Master Plasterers, and the National Association of Operative Plasterers.

The President reported that the other Federations had now paid the apportionments due from them on the National Reserve Fund Account. On the motion of Mr. A. J. Forsdike, seconded by Mr. Sinclair, it was resolved to send a special circular to the local associations requesting that this matter be given urgent attention not later than September 30th, with a view to the amount allotted to the Federation being honoured by the end of the year.

The recommendation of the National Administrative Committee with respect to the journal being supplied to local association members at a reduced charge and the balance of cost being paid out of the funds of the local association was considered. On the motion of Councillor J. Dawson, seconded by Mr. T. E. Taylor, the Federation expressed their sympathy with the efforts to extend the influence of the Journal, but were strongly of opinion that the resolution of the Administrative Committee should be altered to read in the form of a recommendation only, and not of a resolution binding upon all local associations.

A letter was read from the Wakefield Association recommending the Council to have the report of Mr. Sinclair presented at the last meeting of the Council (on his recent visit to the Continent to inspect housing and town planning) printed and circulated amongst the members of local associations. It was pointed out that an official and exhaustive report had been issued by the Housing Reform Council at a cost of 3d. per copy.

A letter was read from the Nottingham Association asking whether charges were made for water supplied to baths having no direct connection, but being filled by a tap from the copper, and emptied by a waste pipe which forms the swivel. It was stated that similar letters had been sent direct to local associations, and that suitable replies had already been forwarded.

Mr. E. Quibell, president of the Hull branch, called the attention of the Federation to what they considered to be an injustice to one of their members.

As more is likely to be heard of the case, the particulars are for the present withheld. In discussing the case strong emphasis was again placed on the absolute necessity of contractors continuing their agitation for the insertion of an arbitration clause in all contracts.

A letter was read from the Sheffield Association stating that the association had agreed with the bricklayers for one hour's notice being given on leaving, provided that there be no cessation of work during the said notice. Mr. Forsdike stated that the Sheffield Association were desirous of obtaining the Federation's consent to notices being given to the bricklayers and joiners with respect to walking time. On the motion of Mr. Sinclair, seconded by Councillor G. Mansfield, J.P., the Sheffield Association were empowered to give notice accordingly, if such step is deemed necessary or expedient. On the motion of Mr. J. Biggin, seconded by Alderman J. Birch, J.P., it was resolved, in view of the prevalence of holidays and the visit of the Belgian builders to Sheffield, that the Federation do not meet during August, and that the president and secretary be empowered to make the necessary arrangements for the September meeting.

The president and members of the Scarborough Association afterwards entertained the members to tea, and a hearty vote of thanks was accorded to them for their generous hospitality.—J. DAVIDSON.

BRADFORD ASSOCIATION.

Joint Secretaries: J. Davidson and J. H. Hopkinson.

The monthly meeting of the Bradford Association was held at the Builders' Exchange, Bradford, on Tuesday, July 27th. The president (Mr. T. E. Taylor) and several members were present. The treasurer presented his report, and the President expressed the great pleasure he had experienced at the last Federation meeting, when it was reported that the Bradford Association had paid its subscription and reserve fund contribution for the current year. The minutes of the Yorkshire Federation were read and considered, and a very interesting discussion took place on the case of the Hull joiner and Hull city architect. The form of subcontract remitted by the Federation for the observations of the local Associations was considered clause by clause, and several suggestions were agreed upon for recommendation to the Federation. Mr. R. Raper reported on the proceedings of the National Federation meetings at Portsmouth.

LEEDS ASSOCIATION.

Secretary: J. Davidson.

The Leeds Association has recently lost one of its oldest and most respected members by the sudden and sad decease of the late Mr. Charles Myers. His death took place while returning from Canada, after visiting a daughter and other relatives. During his career he had taken an active interest in public affairs, and was for many years a members of the Leeds Council. He was in frequent request in connection with arbitration proceedings, and his wide experience and expert knowledge eminently fitted him to act either as arbitrator or witness. A resolution of profound sympathy has been forwarded by the Association, and the President (Mr. W. Irwin) and several members were present at the funeral service and interment, which was largely attended. Messrs. W. T. Ledgard and J. H. Tomlinson were also present as representatives of the Yorkshire Federation.

REDDITCH ASSOCIATION.

Secretary: F. Turner.

The annual outing of the Redditch Master Builders' Association took place on Saturday, the 10th inst., when the members of the Association, their clerks and secretary, to the number of 20, had an enjoyable drive in a char-a-banc supplied by Messrs M. Huntley and Son. A start was made from Redditch at 8.30 a.m., and Evesham was reached about ten o'clock. After wandering about the town, a well-served dinner, over which the President of the Association (Mr. H. J. Surman) presided, was partaken of at the "Rose and Crown" Hotel, High Street, after which the President proposed the usual loyal toast. The party then proceeded to Broadway, when an hour was well spent in viewing the ancient village, and then to Bidford, where tea, provided by Mr. Holland, was served. A steamer was then chartered, and a trip taken to Cleve Mill. On the return to Bidford a cricket match was held, two teams being picked, of which Mr. Surman and Mr. Newbould were the respective captains, Mr. Surman's team being victorious. The arrangements for the outing were made by Messrs. Newbould and Edkins, and were admirably carried out. The President proposed that a hearty vote of thanks be accorded to these gentlemen for the trouble they had taken. Mr. F. C. Huins seconded. The proposition was carried unanimously, and Messrs. Newbould and Edkins responded. Redditch was reached about 10.30 p.m., and all present agreed that they had had an enjoyable time.

BARNSLEY ASSOCIATION.

Secretary: J. Denton.

The monthly meeting was held on the 14th ult., Councillor G. Haigh in the chair. An important discussion on the proposed amended form of sub-letting agreement was initiated by Mr. T. Lindley, drawing attention to the provision in the clause on the insurance of the building in progress, that each trade should bear its share of the cost of insuring. The builder had usually a clause in his quantities to that effect, but the other trades had no such clause. Mr. F. Goodyer replied that the builder would naturally fill in the item for the whole of the trades. The President also confirmed this as the usual course. Mr. Lindley submitted that as the sub-contract agreement contained a clause making the sub-contractor liable for his share of the insurance, the sub-contractors' quantities should also have an item to the same effect. The Vice-President, Mr. E. Broley, was of opinion that Mr. Lindley had wrongly interpreted the insurance clause, and that the sub-contractor had no liability whatever. Mr. Lindley admitted that he might have done so, but was not sure, and he suggested that the Barnsley delegates should raise the question at the next meeting of the Yorkshire Federation:—"Whether, in case of fire or other damage to building still in the hands of the builder, the builder would bear the whole cost of the insurance, or whether the sub-contractors would be expected to share the cost." The builder members generally thought that some of the clauses were too drastic, but on the other hand, the sub-traders thought they were fair and impartial. The arbitration clause in particular was very adversely criticised by the builder members. The President remarked that the agreement was all in favour of the sub-contractor. Ultimately the agreement was unanimously approved on condition that the delegates asked the question concerning the insurance clause at the next Yorkshire Federation meeting. The proposal to build new tea-rooms near the entrance to the Park, and the alleged infringement of the local by-laws in not keeping the proposed new building within the building lines, was next discussed. Several members criticised the action of the Corporation, stress being laid upon an act of injustice done to one of the members over an alleged infringement of the by-laws. It was held that as the Corporation made the by-laws they should certainly be the last body to infringe them. The Hon. Secretary was instructed to draft a letter to the Parks Committee containing a copy of the resolution unanimously approved, viz.: "That the Burial Boards and Parks Committee be asked to rigidly adhere to the by-laws—that is, to observe the building line in connection with the building of the new tea-rooms." Mr. Lindley, as the President of the National Master Plasterers' Association, submitted an abstract of the new rules to be laid before the half-yearly conference of the National Federation at Portsmouth, for their confirmation. The President urged the members to rally around the Sheffield Association and make the visit of the Belgian builders a success.

The annual outing of the Barnsley Federation of Building Trade Employers took place on Thursday, July 8th ult. The party, to the number of fifty, were conveyed in motor char-a-bancs to Wentworth-Woodhouse, the beautiful residence of the Earl of Fitzwilliam. The party, who had a special permit to view the inside of the house, were conducted through the various rooms by the housekeeper, the priceless works of art, historical family relics of Charles the First, being courteously explained to the members by that lady. During the afternoon the annual cricket match was played, "Builders" versus "Rest of Federation," resulting in the usual decisive defeat of the "Builders," the scores reading: "Rest of Federation" 48, "Builders" 18. The ladies of the party were specially catered for in a motor char-a-banc run in and around the beautiful surrounding country. The evening was devoted to singing and the usual excuses by the "Builders" of their defeat. However, all things good and otherwise come to an end, and one of the most enjoyable outings in the history of the Federation terminated amidst the good wishes of all concerned.

LEEDS FIRECLAY CO.'S EXHIBITION FOR THE HEALTH CONGRESS.

Trade and Craft.

The members of the recent Health Congress held at Leeds were invited to visit the works of the Leeds Fireclay Co., Ltd., on the Tuesday, Wednesday, and Thursday afternoons, and large numbers availed themselves of the privilege. At their Royds Works, a special exhibition of which an illustration is given, had been prepared showing the products of the company's various works, including a section of a swimming bath, a park urinal in vitreous terra cotta, closet partitions and workmen's shower baths erected in patent partition bricks, as well as examples of the company's well-known productions in the way of glazed bricks, terra cotta, porcelain baths, lavatories, drainage specialities, etc., etc. Among the visitors were a considerable number of medical officers of health, surveyors, and sanitary inspectors, who were specially interested in the display of novelties in the way of school lavatories and urinals. The company provided tea and other refreshments for the visitors.

A scheme for a gigantic railway goods clearing-house in London is being mooted by Mr. A. W. Gattie, Mr. Guy Lloyd, A.M.Inst.C.E., and Mr. A. G. Seaman, M.Inst.E.E. The object is to facilitate transit, relieve congestion, and render unnecessary some 75 per cent. of the goods vans that at present cumber the streets. The basis of the proposal is the use of the patent electric sorting and handling machinery, invented by Mr. Gattie. The clearing-house would be erected at a centre connecting all the systems of London. Plans for it have been prepared by Mr. R. Stephen Ayling, A.R.I.B.A. There is some idea of applying the invention to the handling of parcels in the post. By merely pressing a button a parcel could be sorted for Manchester or Birmingham, as the case might be; and the machinery will deal with anything from a postcard to a heavy bale.

* * *

The Oldham Corporation have recently adopted a new fair contracts clause after consultation with the master builders and the local Trades Council. It has, however, not given satisfaction to either of the two parties. The Trades Council have condemned portions of the clause, and a letter was read at the Finance Committee's meeting from the Oldham Master Builders' Association complaining of the unfairness of a section of the clause which provides that the corporation can impose a penalty up to £500 for the breach of a contract. The association contended that the penalty should be fixed by an independent person, and they should have the right of appeal to arbitration against the corporation's decision on the question of a breach of contract. They also asked that a deputation should be allowed to appear before them on the question. It was suggested that the clause be allowed to remain as it is, as the section would not be put into operation in one out of five thousand cases. It was ultimately decided to wait and see if any complaint came from the Trades Council.

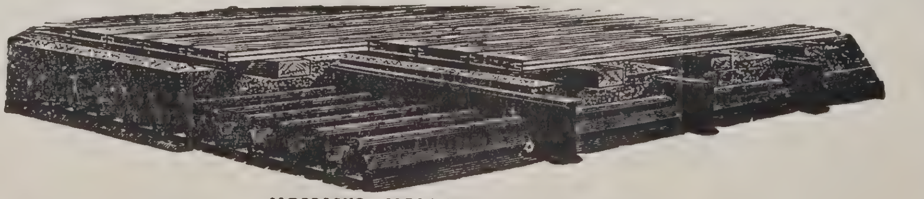
* * *

A Local Government Board inquiry has been held in Bedford regarding the proposal of the Bedford Corporation to borrow £15,000 for a dust destructor, £25,775 for completion of the water supply scheme, and £11,000 for enlarging the mains.

Homan's Fire-Resisting Floors

Have been executed in over 3,000 Buildings, and are the most efficient and economical.

Constructional
Steelwork of all kinds,
Cast Iron Columns,
Concrete Staircases,
Granitic Work,
Asphalte,
on Roofs, etc.



HOMAN'S HOLLOW-BRICK FLOOR.

Advantages of this Construction:—
No centering required,
Rapidity of Construction,
Is practically sound proof,
Qualities:—
Light in weight,
No discoloration of ceilings,
No hacking of ceilings, the grooved bricks giving an excellent key for plaster,
Moderate in price.

Technical Journals, Ltd.,
Caxton House, Westminster, London.

The Largest Educational Institution in the World offers you a thorough

Technical Training
IN YOUR OWN HOME

—in your spare time—and on terms to suit your pocket.

Whatever your circumstances may be, the way to a high-grade position in your chosen occupation is opened, straight and clear, before you—you have an equal opportunity to that of the men who have had the advantage over you through educational or financial position!

The International Correspondence Schools have a brilliantly successful record of 17 years in training ambitious workers for advancement. *You can have an I.C.S. Course arranged to meet your special needs.*

Throughout your Course, your *individual requirements* receive the attention of experts holding the highest qualifications in both the theory and practice of their subjects. However elementary, or however advanced, may be your knowledge, you are coached from your present standard right through to fullest competence for a good position. And you are saved the inconvenience and loss of time which classes entail.

In *every* way, indeed, the I.C.S. system is the *efficient* system.

Residents of the following Countries should address the respective I.C.S. Branches:—
Canada—Toronto.
India—Fort, Bombay.
South Africa—Cape Town.
New Zealand—Wellington.
Australia—Sydney.
Italy—Naples.
China—Shanghai.
P.I.—Manila.
Honolulu—Honolulu.
Panama—Ancon.
Bermuda—Hamilton.
Straits Settlements—Singapore.
Porto Rico—San Juan.
Jamaica—Kingston.
Mexico—Mexico D.F.
Argentine Republic—Buenos Aires

Here is typical testimony:—

"KEARSLEY, near MANCHESTER.

When I enrolled in the I.C.S. I was a joiner. Feeling the need of a technical education to help me master the more difficult problems in connection with my work, I decided to devote my time and energy to the study of Architecture. I first began at the Technical School with building Construction and Mathematics, but I found after two years' study that I was not making much progress owing to the lack of individual instruction. I then decided to take up your Complete Architectural Course, and since doing so I have succeeded beyond my expectations. I have designed several buildings, villas, etc., which have been erected under my supervision, and this I attribute largely to the helpful and instructive manner in which my studies have been conducted. In conclusion, I may add that I have received private instruction in Architecture and Surveying for which I have paid 10/6 per lesson, but I have found your system of instruction to be the best.

(Signed) HERBERT HORSFALL."

An important side of our organisation is **"OUR STUDENTS' AID DEPARTMENT,"** which is in close touch with employers in every district, and devotes its entire attention to assisting I.C.S. students in the matter of employment by recommendations, introductions, etc. Send for full particulars about this valuable service. Mark the Coupon or write us about any special career—NOW.

Basement Houses.

One of the speakers at the Health Congress stated that in an ideal city there would be no houses with basements, which help to spread disease, and especially tuberculosis. The disfavour with which basement houses are at present regarded—a fact which is causing great trouble to the ratepayers and corporations of various districts in and around London—is not due, however, to any fear about the hygienic disadvantage, but to the more mundane reasons that it involves more running up and down stairs, and that the basement is especially disliked by servants. The question of running up and down stairs could be quite easily solved by putting in an ordinary or a service lift, a remedy that is practically the rule in London West-End basement houses, always in certain demand because of their situation. The real reason is that the servants, especially if there are only one or two, do not care to live in the basement, and therefore will not stay in a basement house, and as it is easier to get houses than servants, the basement house is becoming a drug on the market. How to convert a basement house is a very difficult problem. Practically the easiest way would be to lower the ground round the house, or put in much larger areas. To put in a false floor makes the ground floor too high, and yet not sufficiently so to allow of a mezzanine. When one considers the very large districts in the London area which are practically covered with suburban houses, it is more or less certain that this problem of the conversion of basement houses will have to be tackled, and the owners of this class of property might do worse than institute a competition for the best method of doing the work.

Improvements?

If the authorities of Croydon have flattered themselves that their ideas of progress would receive an official blessing from the general Press, they must by this time have been disagreeably surprised. Both the daily and weekly papers of all shades of political opinion unhesitatingly condemn the proposal to pull down the Whitgift Hospital, which, as stated by one daily, "is the only building which gives that town distinction." Evidently the words "Progress" and "Improvements" are not so all-sufficing in an argument as they once were. Another "improvement" is the probable removal of the statue of Charles I. at Charing Cross to improve the approach to the new entrance to the Mall. What at first promised to be a very fine entrance seems likely to turn out poorly in result—not through any fault of the architect, but through the stinginess of Government departments, which could not countenance the erection of a purely decorative feature like the Arc de Triomphe at Paris. The Mall arch has been used to provide additional rooms for the Admiralty, and, in consequence, the whole erection is ruined from the architectural and town-planning points of view. As the "Morning Advertiser" leader says: "The Charles' I. statue ought not to be moved merely in order to improve the unimprovable. It is a remarkable fact that our authorities, whether city or municipal, seem to have the most inadequate idea as to the value of old buildings and memorials. When they sweep them away, they always speak of improving things; whereas nothing new in this country is an improvement on the old. It is generally Americans who estimate England's old buildings at their proper value. Every Town Councillor ought to be compelled to spend at least a year in the States, or in the Colonies, in order to learn how to appreciate what he seems to dispise in this country." We do not think that an architect could put the matter better.

Back-to-back Houses.

The controversy on back-to-back houses in the "Yorkshire Daily Post" has assumed extraordinary proportions. So far as Leeds is concerned, opinion is very sharply divided on the merits and demerits of the back-to-back type of house. Though we ourselves are strenuously opposed to any enactment which would encourage or allow the further erection of such dwellings, it would be idle to contend that the protagonists of this type have not made out certain points in favour of it. The principal advantage is the fact that whatever space of ground is allotted to the house, occurs all in one piece, and the miserable back yard and front garden of the average "through" house, too small separately to be of any value, when put together form a respectable kind of yard or garden. The other point which is advanced by many correspondents is that these houses are not so crowded on the land as is the case with the "through" type of house. The rows of houses are 66ft. apart, and one writer states that though "through" scullery houses (by which we take it he means houses with a kitchen-living room and separate scullery) can be built 48 to the acre, other small "throughs" in other towns are built 82 to the acre, and the modern back-to-back only 44 to the acre. The only point about these figures is the apparent generosity of the owners who are content to have only 44 houses to the acre, instead of the 48 or 82 which they might have. If these figures are to be trusted, the Yorkshire owner must be acclaimed as of more generous disposition than the owners in most parts of the United Kingdom. Very much depends on the width of the streets and the back-to-back houses. It is doubtful if legal enactments can decide how much open ground should be left in front of such houses. As regards cleanliness, it is the people more than the houses which are in fault. The question which would naturally arise in most minds is whether the back-to-back type of house gives more opportunities for dirt and neglect than the "through" type of house.

Cottage Dwellings.

It is a sign of the times that at the annual meeting of the Improved Industrial Dwellings Company the Chairman should have felt it necessary to state that the big block tenement was now a thing of the past, and it would not be wise to build more of them. There is no doubt that the public is being so quickly educated to the advantages of cottages on Garden City principles, that it is not likely to want to live in "layers," as one writer not inappropriately terms it. But it is particularly desirable, if we are going to build horizontally instead of vertically, that we should build on some definite plan. In such case, London will spread out in all directions, and if the question of main roads is not carefully considered in connection, it will be almost impossible to get in and out of it by road under half a day's journey. The authorities at Paris, now engaged on the levelling of the fortifications, have a better idea how to do these things. The destruction of the fortifications marks a great change in the building ideas of Paris. It is well known that Paris is a city of flats and that Parisians have been forced to build upwards because of the natural limitations of space set by the fortifications. Now that these are to disappear, the necessity for building flats outside the line of the fortifications disappears. The Garden City Association of France and the authorities are already working on a scheme to devote a large part of the space, formerly covered by the fortifications, for the purpose of public gardens, thus forming a belt of green and trees all around the city. Something of the same idea should be thought out in connection with the spread of London. We have again and again called attention in these columns to the nature of the property which is being put up all round London, and the recent inspection by a Local Government Board inspector at Enfield only emphasises what has already been said. "Before the present century is half through, all round London will exist a network of slums, infinitely worse than those once found in the centre of the Metropolis. These were often overcrowded, but many had the merit of being well and substantially built. It was only the grasping nature of the landlords and the filthy habits of the people that combined to bring them to their evil state. Within a few years jerry-built houses will be uninhabitable. It is impossible for it to be otherwise. A well-built house can be restored, but you cannot do this when the structure is rotten from top to bottom." This intimation of the "Bradford Daily Telegraph" is followed by an enquiry as to what the Health Committee's By-Law Committee and Inspectors have been doing to allow this kind of thing. Probably some of the property in question was erected before the by-laws were properly administered, but much of the bad building is due not to bad material, over which the authorities can exercise some control, but to the bad methods of putting it together, generally due to the fact that the speculative builder sub-lets the work, and fails to exercise due supervision over the men who carry out the various trades on piece-work. In a number of speculative houses lately brought to our notice, the woodwork is perfectly sound, but it might have been cut with a hatchet. The defects in the joints had been made good with stopping, and painted over, and this kind of work was only typical of the rest of the construction.

Representation in the Lords. The proposal, which Earl Wemyss has embodied in two resolutions to be moved in the House of Lords, by which a certain number of peers are to be delegated to represent each of the National Trading and other Societies and Institutions, is a proposal which may have a certain political object, but on general grounds cannot fail to commend itself to the members of the learned professions and organised trades. It is by the Upper House that all legislative proposals should be subjected to a close and scientific scrutiny before they are passed into law; and in the nature of things cautious deliberation and detached survey of the possibilities of legislation cannot be expected in the House of Commons, which is necessarily swayed by the clash of interests and the requirements of party loyalty, inherent defects in all popularly elected bodies. But the Peers should be in a position to give a more mature consideration to the measures that come before them, and to have at command the views of the "organised brains of the Nation" should be of material value in the conduct of their deliberations. Architecture and architects invariably obtain such a poor hearing from our legislative bodies that it is not surprising to find the Royal Institute of British Architects and the Royal Academy of Arts in the forefront of the societies and institutions that approve of Earl Wemyss' idea; and the National Federation of Building Trades' Employers is among the supporters of the movement.

GERMAN DECORATION.

That the German temperament demands very different surroundings to that of the English is very clearly evidenced by the characted of the decoration and furnishing in modern German houses. Readers who have seen illustrations of German interiors will not need to be told how bad the general level of the work is; so bad in fact that it can only be explained by some trait in the national character which is not clearly understood by English people. A writer in the "Westminster Gazette" gives some interesting particulars of the decoration of modern flats which will probably convey to readers not acquainted with German work some idea of the extremities to which Art Nouveau can go. For instance, it is in decorative details that the Berlin architect shows his uncivilised taste, and lack of knowledge of the fitness of things. The underlying idea is that a dwelling-house is something apocalyptic and awe-inspiring. The statuary—and nearly all houses have statuary or carved stone—is always of this character. Some houses boast artificially pitted gargoyles, which might have come from Notre Dame. Others are adorned with sphinxes. Scraggy or enormously fat nude females project from over every second window. Even angels blowing trumpets appear, and one house may be seen with a citation from Bismarck emblazoned in blue and white mosaic on the facade. The top central window of a house is shaped like an enormous mouth, and above this mouth are painted in purple a "Kaiser moustache" and a pair of gigantic eyes topped with gold mosaic eyebrows. The interiors of only the very latest flats are decently decorated, and not many of these. The Berlin decorator can leave nothing alone. You see, for instance, an entrance-hall behind the common door of the flat-house, a hall with walls of plain oak-panelling done in excellent style. But the decorator, for some crazy reason, in some prominent place will have stuck up a highly carved panel with some ugly design, and all the relief parts gilded gorgeously, and even sometimes coloured. Marble is used in many of these halls, but it is almost always gilt in parts, or broken with masses of cheap mirrors, which recall publichouses. The staircases are lighted with stained-glass windows, treated in melancholy Secessionist style. Some of the latest flats have hall-doors painted pale greens and yellows and decorated with coloured bands, silver stars, and other tawdry figures. One I came across had all letter-box slits shaped like drooping mouths. It is, however, the electric lamps in hall and on staircase which show Berlin taste at its worst. The Berlin lamp manufacturer's ingenuity knows no limit. One great hall lamp carries on top an immense pink plaster Nereid seated on a glittering dolphin, from which, instead of fins, project two gigantic imitation stags' antlers, from the points of which, in turn, hang electric bulbs. In another house is a vast chandelier shaped as a tree, on the branches of which sat owls, out of whose eyes gleaned electric light. Underneath hung the strings of cheap green glass beads without which no New Art lamp is considered complete. With all the advance in German education, it is astonishing that such crudeness should still persist.

The interior of the vast majority of these little flats show no more taste, but they meet the needs of the German middle-class, which above all things dreads simplicity, dreads it so much that sometimes you will find an advocate or doctor of good position who will hang strings of dusty artificial flowers across his entrance hall. You will find quite small flats which in the nature of things would be cheaply furnished, the ceilings of which are gorgeously decorated with gilding and colours. The very newest flats show a reaction against this, and some decorators are daring enough to paint their entrance halls a plain white, and leave the ceilings alone—except for an innocent moulding.

Architects of the Day.

III.

Mr. Mervyn Edmund Macartney, B.A., F.R.I.B.A., F.S.A.

Mr. Mervyn Macartney took his B.A. degree at Lincoln College, Oxford, in 1877, whence he proceeded to Mr. Norman Shaw's office. While there he received his first commission to erect some studios in the West End, and from that time he has been busily employed, chiefly in domestic practice.

His name is intimately associated with the revival of the Renaissance tradition. Even during the time he was a pupil with Mr. Norman Shaw, whose practice at that time was entirely in the older tradition, he was a whole-hearted Palladian, and his influence since then has been exerted to cause the dropped threads of this tradition to be gathered together.

We are scarcely able to understand the difficulties which had to be overcome by the pioneers in this work, for to-day the general trend is in the direction of the Renaissance.

The essence of this, as of the classic styles, is proportion, and this Mr. Macartney considers the vital quality of architecture.

It is a small matter, perhaps, but the proportion of glass panes is to him a matter of importance, and this consideration affects the design of the windows themselves, so, in the same way, every feature is considered in relation to the whole. It can be conceived that this view of the Renaissance allows of the utmost simplicity, and many of Mr. Macartney's houses are noticeable by the absence of all whigmalieries and fussiness. In small houses and cottages he is exeremely fond of using an oblong plan with a simple tipped roof over it—quite plain, but possessing an intimate charm and a homelike quality, in marked difference to the self-conscious cottage building that is so much affected in garden suburbs.

While preparing, in conjunction with Mr. Belcher, his most important book, "The Later Renaissance in England," Mr. Macartney cycled over nearly the whole of England, and his wide knowledge of this style is a source of embarrassment to his friends, who, knowing his interest, keep him apprised of their finds, though it is seldom they discover anything not already known to him. It is interesting to know that this book is well considered in America, where it is regarded as a text book.

In the recent revival of the crafts, Mr. Macartney was a prime mover. He was one of the founders of the Artworkers' Guild, and occasionally exhibited at their exhibitions pieces of furniture made from his designs, which are always marked by a playful originality, never *outré*, but with a quiet unobtrusive touch of scholarship. For himself, however, he prefers antique things, and he possesses a splendid collection of old furniture, silver, and china.

A pioneer in many things—in architectural education, in town planning—he was one of the first men to re-introduce architectural planning of gardens. We do not mean formality carried to the extreme, but a considered disposition of terrace, garden wall, pond, and accessories of this kind. Of flowers he is passionately fond, and no garden of his but has its long herbacious border flanking a path.

The garden at Frithwood House, Northwood, near Pinner, is a very good example of his work. It is laid out on a sloping piece of ground, two brick terraces with pleasantly arranged steps are placed in front of the house, and in the axial line is a wonderful bower of roses trained in a quite Oriental fashion, with flower gardens all round and a fish pond at the side.

His recent book on "English Houses and Gardens of the 17th and 18th Centuries," will be fresh in the minds of readers. It consists of a number of illustrations of old houses and gardens reproduced from engravings by Kip and others. His notes display a wide knowledge of the subject.

It is to be regretted that Mr. Macartney has not done more public work. His design for the South Kensington Museum was marked by vigorous simplicity. The front was composed of great masses of masonry in several planes, very severe, but there can be little doubt that it would have made a magnificent building.

More recently he submitted a fine scheme for the Strand Crescent. In these works he displayed an exhaustive knowledge of the Renaissance illuminated with real thought, and inspired by a splendid feeling for proportion.

Unfortunately, his houses—a number of them in the neighbourhood of Tunbridge Wells—are not easily accessible, but they are all restful pieces of architecture.

In many counties, he has built in the vernacular, in brick, in stone, tile, and slate, with consummate mastery of his materials. And many of his houses to-day look as if they were part and parcel of the country-side they adorn. One of the early houses, "Kent Hatch," Westerham, is a large, half-timber building, evidently inspired by Mr. Shaw's work. "Court Hayes," Oxted, another early work, in brick and stone, has a fine architectural terrace. "Shandon," Tunbridge Wells; "Champions," "Scearn Bank," "Sandhills," are large houses all in Surrey.

Bussock Wood, near Newbury, the subject of our centre plate, is a recent work of Mr. Macartney, and has been built for Sir M. F. Montagu-Pollock, Bart. It is situated on some rising ground a few miles to the north of Newbury, close to the remains of a British camp. The south front commands fine views over a hilly country, and through a gap in the trees the tower of Newbury Church can be seen. The main entrance, on the north side, approaches the house at right angles through a thick wood. The walls are built of a local red brick, with dressings of Portland stone, and the roof is covered with old tiles. The eaves cornice is of wood. The gardens are being laid out in a formal manner; the fish pond is shown on the view of the south front. The forecourt is surrounded with walls, but the photograph was taken before they were built.

"Swaylands," Kent, is a huge place, the front extending for 500 ft. Mr. Macartney added the conservatory, picture gallery, etc. He built a new boarding-house at Bradfield College, in a quiet Georgian style.

"Welders," at Chalfont, St. Peters, Bucks., is an extremely interesting building. The front consists of three gables with rounded tips, very cleverly designed. Mr. Macartney has also built farmhouses in Kent, Somerset, and Sussex.

At Angley Park, near Cranbrook, Kent, he built several gate lodges, cottages, and made additions to the house. The house is some sixty years old, and a very poor piece of architecture. Mr. Macartney's work was entirely in the interior.

Frithwood House, Northwood, near Pinner, is a quiet, Georgian house in brick and tiles, very simple and effective. A town house of Mr. Macartney's can be seen at 167, Queen's Gate.

The house at Woolhampton, which is now illustrated, is on the point of completion, and is Mr. Macartney's third home. Readers of the "Builders' Journal" will remember the interiors of his first house at 52a, Berkeley Square, which was published April 13th, 1904, and of his cottage at Silchester Common, published March 23rd, 1904.

Some three years ago Mr. Macartney was appointed the surveyor to St. Paul's Cathedral, and we may rest assured that this, our finest building, is in safe keeping. Soon after his appointment the decorative schemes suddenly stopped. Some recent work of his may be seen in the Chapel of SS. Michael and George, where a new reredos in oak, marble steps and bronze gilt altar rail have recently been installed from his designs.

A useful development of the practice of published measured drawings is the "Practical Exemplar of Architecture," which Mr. Macartney started some years ago in the "Architectural Review," and in which the measured drawings are accompanied by explanatory photographs. The idea of the Exemplar is to teach students and others the relation of architecture by its geometrical representation. The older architects seemed to know intuitively the weight of mouldings and cornices, etc., at various levels, but the present generation cannot without great experience understand this.

Mr. Macartney has many activities. He is an examiner to the Board of Education, also a member of the Board of Architectural Education. Mainly through his efforts and through his researches into the system of architectural education in America, our own system has been largely remodelled, and will, doubtless, be further improved. He is also a member of the Council of the Royal Institute of British Architects, and figures on the Prizes Committee. Following the Editorial Committee of the "Architectural Review," of which he was a member, Mr. Macartney became the Editor of that magazine, a position he still holds. He is also a vice-president of the Architectural and Topographical Society, and a member of Town Planning and other committees. In architectural politics he is an anti-registrationist; and in sport is particularly fond of the good old game of bowls.

It is not only in his work that Mr. Macartney upholds the best tradition of English architecture: his relations with his builders, with his assistants are all marked by consideration and courtesy, and the consequence is the creation of an *esprit de corps*, and a unanimity of ideals, which make for good work.

PRINCIPAL LODGE, ANGLEY PARK, CRANBROOK, KENT. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This is the principal entrance to the estate, the walls being faced with local red bricks, with dressings of Bath stone. The gates are of wrought-iron, and the roofs are covered with old tiles.

THE ECOLE DES BEAUX ARTS.

Its Teaching and Its Influence on American Architecture.

By Paul Cret.

The poor Ecole des Beaux Arts has been the cause of a great deal of writing in America in the past few years. Criticisms, complaints, denunciations are heard everywhere. If an architect, too skillful for his competitors, wins a competition, it is the fault of the Ecole. That the Renaissance, happening in the fifteenth and sixteenth centuries, superseded Gothic, which was old and no more in harmony with the new ideas of men of this period, is the fault of the Ecole. That the generation of artists of the three following centuries were so much in error as to keep on in this way, following out the spirit of the Renaissance, is the fault of the Ecole. What difference does it make if these artists did create masterpieces? What difference does it makes if they did have no prejudices, and that, though they were nearer the spirit of the thirteenth century than we are, and still had the same skilled workmen (which we have not), they nevertheless broke away from the old forms of their own free will. They were wrong, every one of them—or so it has been decided by the critics, who without a doubt alone have a sane judgment, the true artistic method, and, I hope, the way of using both of them.

Meanwhile the Ecole, which is the pretext for all the noise, looks calmly over the river that reflects the Louvre, the water-jet in the courtyard of the Murier springs serenely from its ivy-covered basin, and Poussin and Puget stand calmly oblivious on either side of the entrance gates. Amid these almost cloistral surroundings the students go to spend a few years of a new life, laugh, become enthusiastic, and start in every direction to try in many different countries to put into lasting form their aspirations and personal qualities—high, it may be, or vulgar, ingenious or commonplace.

The critics accuse; the Ecole does not answer. Its function is to give to those who ask for it the only thing a school can give—a method of work. It makes no effort to bring people to its classes; it prints no advertisements, no circulars filled with promises. Its purpose is not to defend nor to promulgate any special theories. The right to teach is the right of everyone at the Ecole—provided, only, he can obtain a sufficient number of followers. And he may teach what he pleases. A newcomer may open an atelier to teach Oceanian or Romanesque, or be a fanatic in Art Nouveau or Tudor—the Ecole does not object. His pupils have selected him, and are following him because they want him, and only so long as they want him. It is the most liberal organisation I know. It was an American who said, some years ago, to one of the professors of the school: "What differentiates your school from those I saw in Italy, in England, and in Austria, is its complete liberalism; the way in which a pupil here is treated as a man—as a man who has the right to select his own master, to choose his own artistic way."

Fifty years ago, at the time of the reaction in favour of the Middle Ages, due mostly to the deep researches of Lassus, Viollet le Duc and others, influential people tried to diminish this liberty by creating a regular course in æsthetics, with examinations—that is, to impose on all students a certain appreciation of beauty. The professor selected for this chair was Viollet le Duc—whose ideas on modern architecture, while excellent for a few, were very bad for the majority. As the pupils of the Beaux Arts are between twenty and thirty years of age, they are no longer schoolboys; and the most of them have the necessary culture to admire what is worth admiring without being told when to admire. There was a sort of revolution, the Government gave way, and only those who wanted to, took the examination in æsthetics. Since then every course, apart from the scientific and technical courses, is optional—and the student does not have to subscribe blindly to any formulæ.

To discuss the methods of the Ecole is, then, a task as endless as the one of the Danaids. The professors are many, and when one dies or retires his place is taken by a younger man with very different ideas. The principles of the Ecole are really those of contemporary French architecture. The professors are nothing more than architects following honestly their profession, with varying success. The only point in common between them is devotion to their art and to their teaching—which is not for them a profession.

As for the pupils, their object in life is not to obtain the Prix de Rome. It is to become more proficient in their profession. But those who obtain the Prix de Rome (who are said with some disdain to have simply proved that they are past masters in scholastic theories and able to teach them to others) are first of all architects, some of whom have built in France buildings whose perfection of study, care in construction and perfect adaptation to modern needs have made them the types of Nineteenth Century Architecture.

We are too near to give recognition to men like Labrouste, Duc, Coquart or Vaudremer; or, rather, most writers on art have not the necessary clearness of mind to appreciate what makes an architectural work a masterpiece, but are largely influenced by the opinions of other people, which they simply adopt as true. That is of small importance; papers do not prevail against monuments, and artistic criticism is the most ridiculous thing to read fifty years afterwards.

That there is a French influence in modern American architecture is true beyond a doubt. The influence does not date back for the last decade, but has been apparent for thirty years at least—to say nothing of the first influence, too rapidly checked, which produced the plan of the city of Washington, and inspired some southern buildings.

Some may wonder that the importation was made without a protest from the general public. "If anyone had attempted to import the railroad system from France, or the banking system, the thing would not have passed so easily. Is it not, then, time to stop and consider?" they ask. Yes, but the importation of French architecture came about because there was a need for it. There would be no point in importing the French railroad system, when the American system, which developed simultaneously with it, is perfectly adjusted to American needs and ideas. But in architecture there is something more in France than in America. The simple fact that it has been brought in without a single protest from the general public is proof enough that the general public could not get along without it.

At the same time the United States was importing formal architecture from France, they were borrowing domestic architecture from England—which is a new proof of what is somewhat compulsory that, in these importations, a nation goes in different ways to different countries to bring back what it wants.

It is remarkable to one who does not satisfy himself with a superficial study of art to see how a power greater than the reason of the individual seems to regulate these transactions—to see how in the Sixteenth Century France borrowed from Italy what it needed to rejuvenate its art—and that without abdicating the smallest portion of her national originality; for I do not believe that anyone conversant with these questions can find a similarity between the French Renaissance and the Italian other than in mere detail or ornamentation.

At the origin of every art there is a foreign influence—no art is national from its beginning. I would be ashamed to write so evident a truth if I had had no opportunity to read monthly dissertations in which it seems to be ignored. The Greek architecture was borrowed, the Roman architecture, the Gothic—but that takes nothing from their glory, which is to have assimilated heterogeneous elements and to have wrought them into a harmonious whole.

In my window one winter I had some tulip bulbs from which I was expecting an abundant bloom of flowers with the first March sun. The green stems came up, but when they reached their full development the buds did not open. Like a poor gardener I had forgotten to let the bulbs stay in the shade to delay their opening and give the roots time to accomplish their work underground, in order that the plant might later on have the necessary strength to bloom. I ask my contemporary not to do as I did. Remember that from having broken too soon the artistic intercourse with Europe, American architects killed Colonial architecture which was so full of promise. They are at work again, accumulating material from France, England, and Italy. The assimilation is going on, the bloom cannot be far off—but you must be patient. Fifty years for the formation of an art does not correspond to five years in the life of a man; and he does not show very strong personality when he is but five years old.

No one can change these laws, which are deeper than the human will. Nobody imposed French architecture on the United States. It was of their own free will that hundreds of Americans went to Paris and that thousands more took their inspiration from the ideas they brought back. Were all these men fools?

What were they looking for in France? and what did they bring back? Documents would have answered the purpose—besides which the importation of forms comes as largely from Italy and England as from France. Then it must have been something more. It was composition and design. The methods now in use all over the United States in the universities, by means of which those who have something to say are enabled to say it clearly, are those of the Ecole. It is there that the real French influence is found. The science of design is not all that it requisite to the professional man, but it is essential to him in order to make himself clear. The more important the subject the more is felt the need of design. But even in a cottage, where a little taste, a little common sense, a little originality, and a sense of the picturesque are enough to create a charming piece of work, these same qualities, unless accompanied by the science of design, result only in disorder, lack of dignity and in a building which is practically bad.

This quality of clearness—the science of harmonious results necessary to design—where could it be better studied than in France? Where could be found a group of men of equal culture and with the same willingness to give up their time, where could be shown so complete a set of representative buildings as in Paris? There is no modern programme that has not there an excellent translation. Other cities have more beautiful work, or a more complete ensemble of monuments of a certain period, but Paris can show types of all periods—which includes the best existing group of modern buildings, theatres, railroad stations, markets, prisons, libraries, and museums.

The Ecole develops in an admirable way the study of design, respect for the programme, and a research of a special character proper for each kind of building. It is as a result of this that in merely looking at a building designed under such principles, one knows immediately its purpose, simply because its plan and elevation correspond to its needs, and it is executed throughout with a respect for artistic truth. The comparison of architecture to-day in the United States with that of twenty years ago shows clearly to every fair-minded man the salutary results achieved by French training for American students.

The greater part of my contemporary's paper was devoted to ridiculing the method by which design is taught. It will seem strange to the reader that such childish methods as he describes should result in the beautiful work they have admired. Here is the reason for this contradition:

A writer speaks of the danger to American students of getting in Paris simply formulæ devoid of sense, and a stock of atelier slang instead of French methods of thought. Discredit has been thrown on the Ecole des Beaux-Arts by such men who, through ignorance, did not catch the spirit of the wonderful training.

ALTERATIONS AT ANGLEY PARK, CRANBROOK, KENT. THE STAIRCASE. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

The staircase is of oak with a carved and pierced balustrade. The marble floor is paved with squares of Verde Antico and bastard statuary

A contemporary saw a "meaningless performance" in the spinning of lines, circles, and grey tones which were to become a plan, he could not see that it was the work of the brain directing it. He was looking at the movement of the fingers, believing in good faith that in this were all the methods of design. Of course, he asked the reason; and as it is sometimes difficult to tell why we do one thing more than another, on account of the complication of things that determined our choice, he was answered with one of those ready-made sentences, the sort of professional slang that the students of the Ecole, or some of them, like to use, because they are short and often avoid long explanations. These he promoted to the rank of canon, of magic formulæ, permitting anyone, professional or layman, to design, "while you wait," anything from a bishop's residence to a railroad station in a Chinese town.

LODGE AT ANGLEY PARK, CRANBROOK, KENT. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A. ARCHITECT.

This, the second of the lodges erected from Mr. Macartney's designs on this estate, is faced with local red bricks and Bath stone.

My contemporary is witty enough not to take offence at the joke played on him by his companions in Paris, in saying there is such a series of formulæ. In the school problems there is such a constant change that it would soon outgrow any set of formulæ. One may notice in the book of competitions for the Prix de Rome, which dates as far back as 1797, a change every ten years corresponding to the change in the art of the period.

It is not the Ecole which creates the architecture of Europe. It is the architects. The students are only pupils following the impulse given by the masters. A great mistake in America has been to take as types the work of students. Whereas the French are more critical and have realised so thoroughly the immaturity of such work that they apply the term "school architecture" to all productions which have good qualities but are undeveloped. It is fair to say that no man produces an architectural work that is representative of himself before he is forty. The complexity of architectural study is responsible for this, and it is only when the different parts of the profession have been mastered that real work can be accomplished.

"The students in the school are taught to plan too much with their eyes," says a critic. Others are planning too much with figures, and of the two excesses I prefer for young men the first. Practical requirements will soon enough cut the wings of his dreams, but something will remain. It is necessary at one period of every man's life that he shall believe that the object of architecture is to produce beautiful things. Those who, during their youth, had only in mind four-foot lightwells instead of Boboli gardens will not in the end do better architecture—even for lightwells.

There are other sweeping accusations. One of these is the elasticity of the school programmes. I have often seen in the United States and elsewhere competition programmes of fifty or a hundred pages, which one had to study for three weeks before starting to design. Now, if one admits that a student can learn how to design by doing one problem a year, let him have such programmes — with all survey information, climatic changes, cost of building and so on. If, on the other hand, one believes it is necessary to have designed much in order to design well, in the same way that one must have painted a great deal to be a painter and that three studies from life, ever so careful and complete, do not accomplish that, the objection is of no value.

Objection is taken more than once to the phraseology used by the Patrons in the ateliers. For instance, a statement taken exception to I discover to be no more nor less than that the situation of a building should have a large influence on the way it is planned—a principle certainly true, if not very startling.

If these formulæ or means of expression were not in sympathy with our critic's way of thinking, and he was going to Paris to study the methods of the school, he should have looked for these methods at the lectures or in the book of the only man who has authority to give them out in the name of the school. Instead of noting without understanding them the sentences which occur in the ateliers (that every intelligent student knows to be only a sort of cloak covering either results or experiments) and processes in presentation of plan, which have no importance to anyone but the newcomer—why did he not read Guadet's book, "The Elements and Theory of Architecture," which is the only authorised document on the modern teaching in the Ecole in the last fifty years. By simply reading the chapter entitled "General Principles," he would have seen that there is no need for complicated

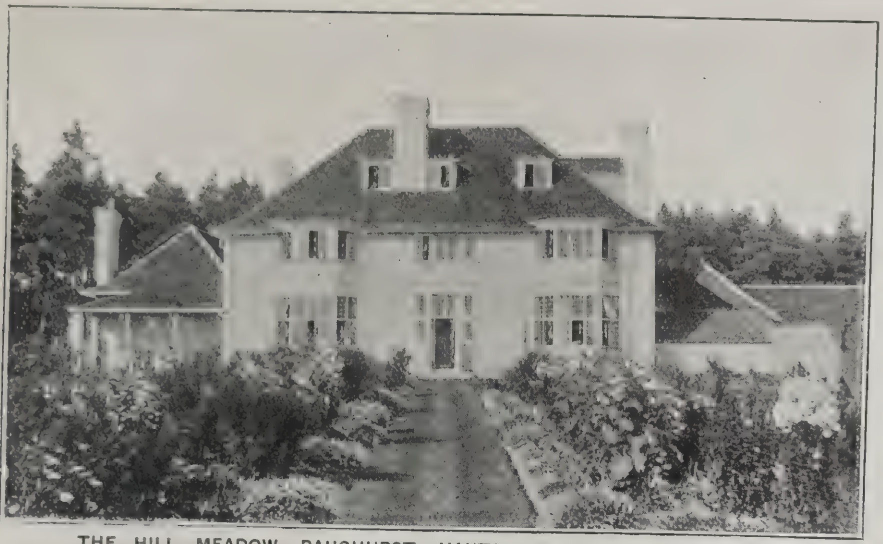
ALTERATIONS AT ANGLEY PARK, CRANBROOK, KENT. THE SMOKING-ROOM. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This house is old and of a poor type of architecture. Mr. Macartney's work consisted of alterations and decorations and the erection of new lodges and cottages.



THE HILL MEADOW, BAUGHURST, HANTS. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This is one of Mr. Macartneys essays in rough-cast, and an exceptionally pleasing house in quiet and simple lines. Our view shows the garden in a more forward state of development than with some of the other houses illustrated here.

words to express what we have all been looking for in the Ecole, and the truths we have taken for a basis. It would have been fairer, in writing of the Ecole, to have taken quotations from such a book, instead of relying on personal impressions, which are subject to the same suspicion as memoirs to the historian. He would have found that what we try to do in making a beautiful plan is not to make a picture. "You must understand by a beautiful plan," writes Guadet, "a plan which allows and is apt to give beautiful things, beautiful interiors, and beautiful facades. Yes, there are beautiful plans—I find the expression perfectly legitimate—but in the same way as there are beautiful books, beautiful by what you can read in them."

Further on (page 134), Guadet sums up the principles of design as he taught them, and as the others—Pascal, Daumet, Laloux taught them to us:

"1. You must be faithful to your programme, be familiar with it; and also see correctly what is the character to be kept in the building.

"2. The ground, location or climate, can modify absolutely the expression of a programme.

"3. All architectural composition must be constructible. Every inconstructible scheme is absurd. Every scheme of construction more difficult or complicated than necessary is mediocre or bad.

"4. Truth is the first requirement of architecture. Every architectural untruth is inexcusable. If in some cases one of these untruths is overlooked on account of the ingenuity and ability shown in the building, the impression given, nevertheless, is of an inferior art.

"5. Effective strength is not sufficient—it must also be apparent.

"6. Designs proceed by necessary sacrifices. A design must be good first of all, but it must also be beautiful. You must compose then with a view both to the utility and beauty of the building. And, as an element of beauty, you will try to obtain character by variety."

The Workington Town Council propose to purchase land for a new technical college and a public park, in Napier-street, as an open space and two fields, at a total cost of £2,395.

* * *

The president of the Royal Institute of British Architects has written to the City Corporation placing the services of that body at their disposal in matters connected with a proposed new bridge over the Thames and the variation in the gradients of Southwark Bridge, and inviting the Corporation to receive a deputation from the Royal Institute on the subject after the vacation.

* * *

The office of the Chief Inspector of Reformatories and Industrial Schools has been removed to Charles-street, Parliament-street, owing to the approaching demolition of various buildings in Great Scotland-yard. Among these are the premises which were originally the chief office of the Metropolitan Police Force. A large block with frontage to Whitehall-place is also to be pulled down, and notices of an auction of the old materials are posted on the walls.

THE PUMP HOUSE, SEDDLESCOMBE, SUSSEX. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This pump-house, which stands on the Village green, has pillars and slates of local stone. The pump is of lead, with cast decoration of cherub's heads, etc., the floor is paved with pebbles, and the seats and woodwork are of oak.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himself of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable; and it must be understood that both question and reply will, as a rule, be published in these columns

Calculation for Steel Girder.

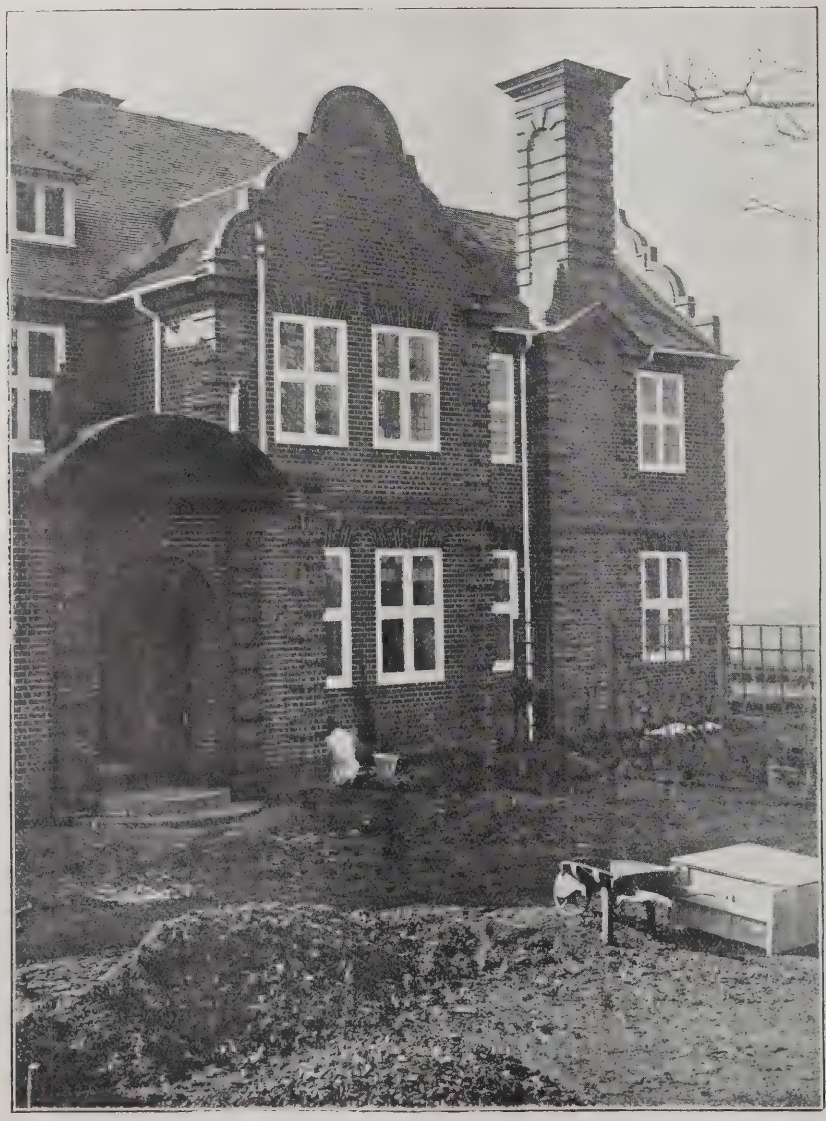
In answer to "Edinburgh" in the "Builders' Journal" recently, your correspondent "A" apparently neglects the flange angles in calculating the flange section. In this particular case the area would be obtained most economically by using two 6in. × 3½in. × ⅜in. angles, giving 6.45 sq. inches of net section or 6.848 sq. inches of gross ditto. Angles are cheaper than plates, and when they afford the necessary section both the expense and the loss of section involved by two rows of rivets are saved. Rivet holes being punched ⅛in. wider than the shank, the deduction for rivets should be either 1in. holes for ⅞in. rivets or ⅞in. holes for ¾in. rivets. ⅞in. rivets are very seldom necessary. In this case with a depth of 3ft.. and a maximum shear of 15 tons, it will be found that ¾in. rivets 4in. pitch would afford ample bearing area even in 5-16in. web.

PERCY J. WALDRAM.

Removing Paint from Oak-work.

CONGLETON.—C. R. H. writes: "What is the best method of removing old paint and varnish from some old oak framing without disturbing the grain, discolouring, or injuring the wood in any way?"

If you use a good paint and varnish remover you will have no trouble with raising the grain, and the wood will not be in any way injured. Probably the best paint and varnish removers on the market are "Pintoff" and "Pyrol." Both of these are made in a paste form. They are applied with a brush and allowed to stand for five to fifteen minutes according to the thickness of the paint to be removed. They do not injure the hands or require any preparation in the removing, excepting a little wiping down with a rag moistened in benzine or turpentine. Ball's paint remover is another excellent article, slightly different in character, and is particularly fitted for removing varnish. J.



HOUSE FOR DR. H. W. GELL, WOOLHAMPTON, BERKSHIRE. THE ENTRANCE FRONT.
MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

Local red bricks are used for the walls throughout, with the exception of the porch, which is built of rubbers. The main cornice is built up of moulded bricks; old tiles are used for roofing and tile-hanging of upper part of walls of of servants' wing. The style of the gables was adopted to suit the client's wishes.

MR. MACARTNEY'S SECOND HOME AT SILCHESTER COMMON.

A distant view of the cottage which Mr. Macartney is vacating for his new house at Woolhampton, illustrated on p. 116. This cottage was illustrated and described in "The Builders' Journal" for March 23rd, 1904.

Valuer's License.

BRISTOL.—E. V. writes: "Is a valuer's license necessary to value a pair of villas for mortgage, and if not, what, if any, stamp duties are payable. I would suggest that if you will give the questions of the altered subjects in the current R.I.B.A., examinations, you will be benefiting a large number of your readers."

An appraiser's licence costs £2 per annum, but it is quite unneeded for the purposes of any valuation which is made for the information of one person only (as in the case of a mortgage, or for probate purposes); a valuer's license is only needed when the valuation is to be made between two persons, and partakes therefore of the nature of an award.—F. S. I. [As to the suggestion of our correspondent, we have anticipated it by arranging for two or three articles on the subject. These will appear shortly.—ED.]

Fumigating Oak in Situ.

LANCASHIRE.—"THOROUGH" writes: "Some choir stalls were fitted in a chancel two years ago; they are of oak, Austrian and Dantzig, and were beeswaxed. It is now required to fumigate them to match some similar work in prospect. Can this be done; if not, what is the best alternative?"

You cannot fumigate this work unless you can enclose the stalls in something of the nature of a box, and this would probably be impracticable. You had better remove the beeswax by means of hot turpentine, and then apply a stain, thinning it as may be necessary to match the new work. A suitable stain can be obtained from any dealer in painters' materials. J.

Gantry Girders.

GLASGOW.—"Crane Girder" writes: (1) Taking, for example, the case of a ten-ton electric overhead traveller, with a span of 60ft. centres of rails, the wheel base will be, say, 10ft., and the maximum load on the end carriage=say 22 tons=11 tons on each wheel. The maximum bending moment for two concentrated loads will either occur with one load at centre of span, or when both loads are on the girder and placed so that one of them is at ¼th the wheel base to either side of the centre span of girder. Please make clear at what ratio of span to wheel base the change takes place, and also what is the maximum BM. when the wheel base is exactly half span of girder. (2) What should be the proportion of depth of girder to span for girders of this type, so that the deflection may not be excessive, and what width should the flanges be in terms of span

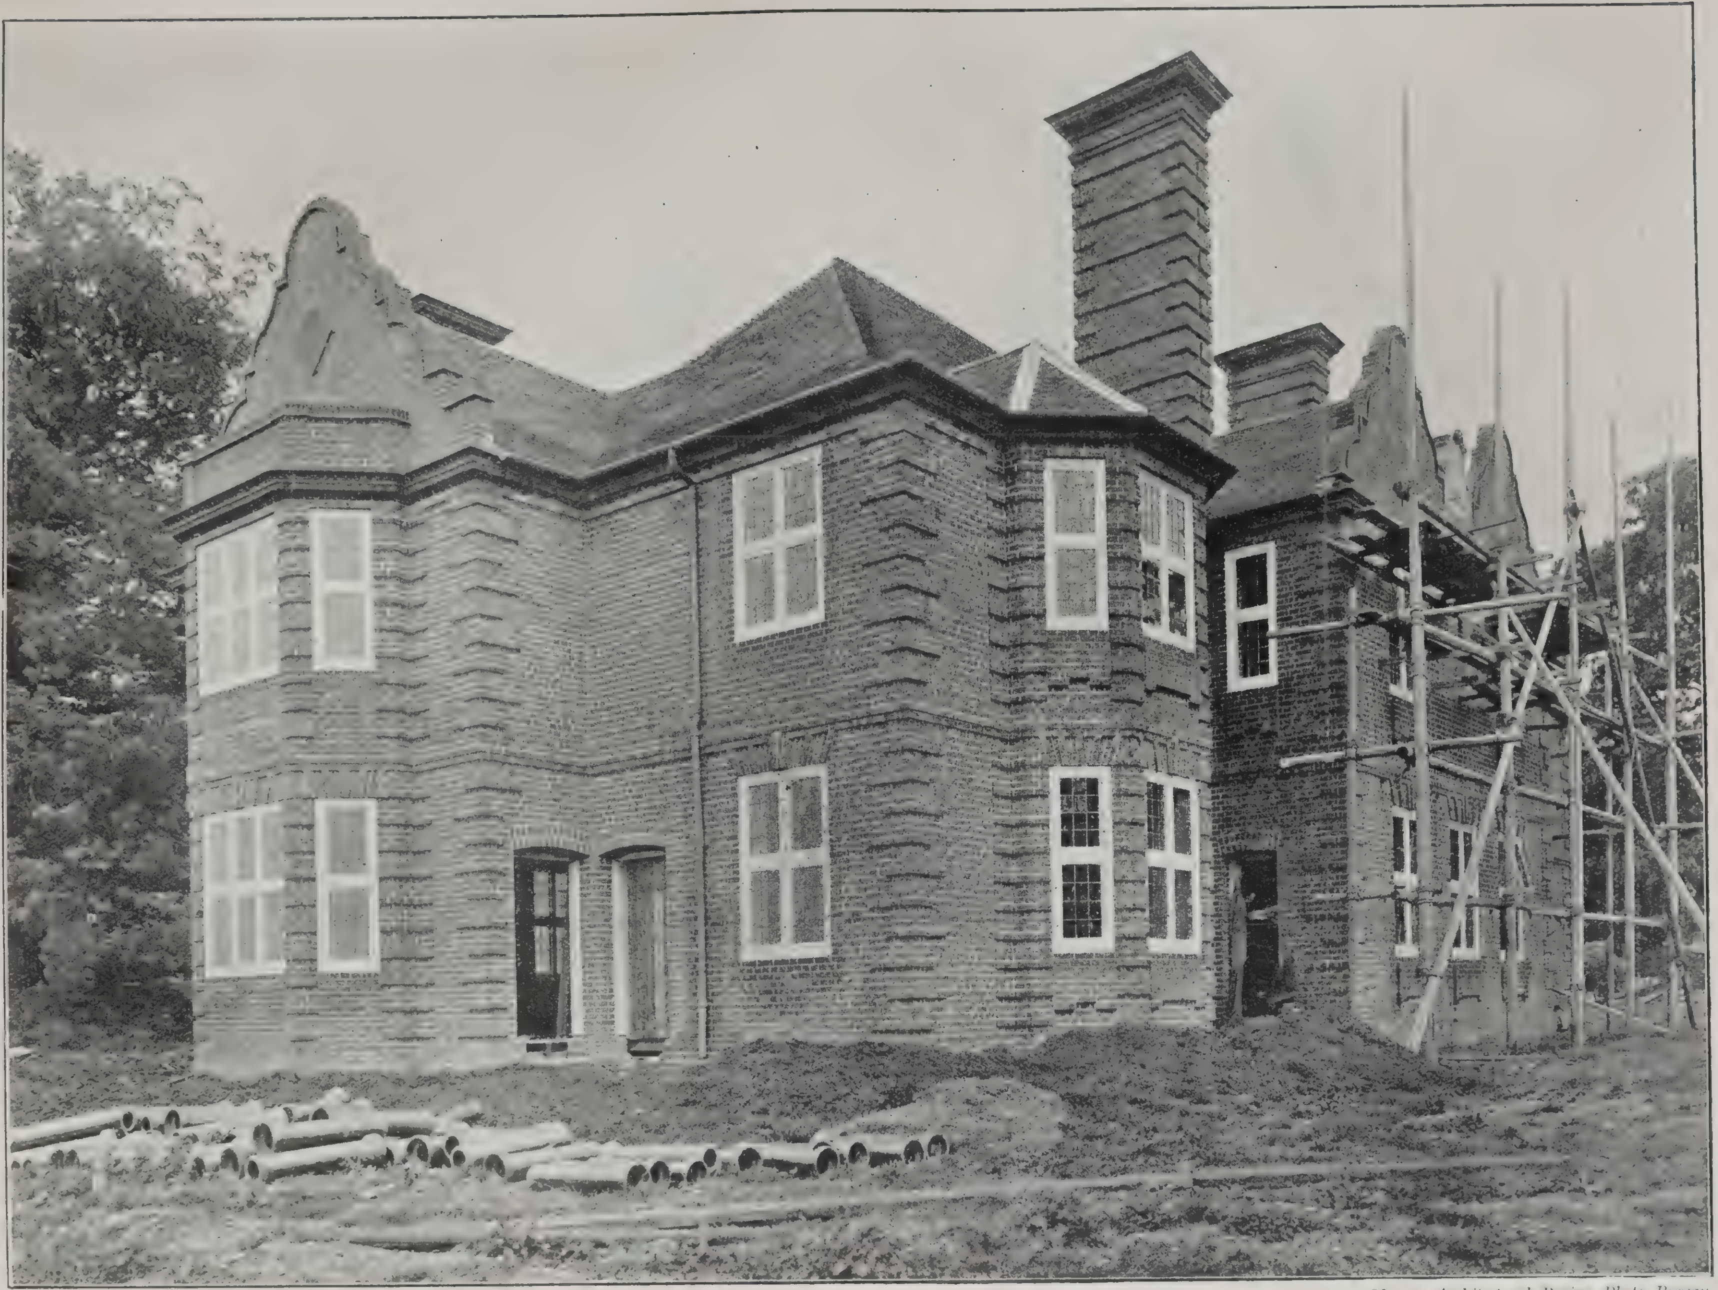


Photo: Architectural Review Photo Bureau.

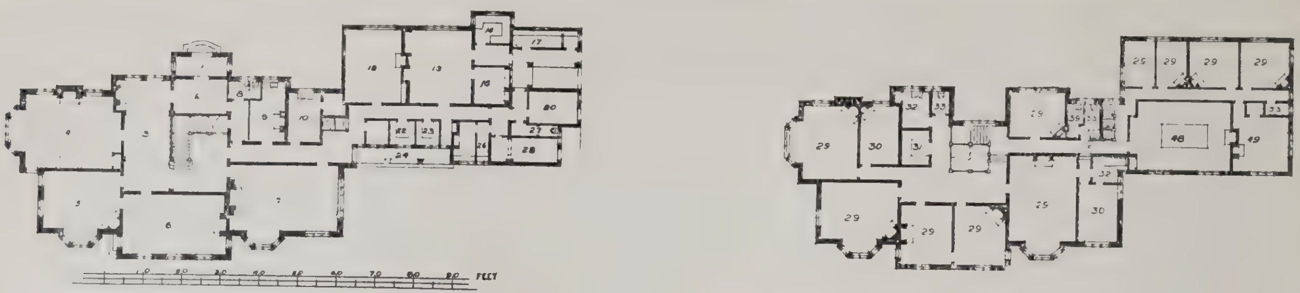
HOUSE FOR DR. H. W. GELL, WOOLHAMPTON, BERKSHIRE. GARDEN FRONT. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This house is situated about six miles to the east of Newbury, Berkshire, and stands on the brow of a hill overlooking the Valley of the Kennet. It commands many fine views in nearly all directions. The view was taken before the erection of the terrace, which now extends along the south and west sides.



HOUSE FOR DR. H. W. GELL, WOOLHAMPTON, BERKSHIRE. PLANS. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

1, Porch ; 2, Entrance Hall ; 3, Hall ; 4, Drawing-room ; 5, Morning-room ; 6, Library ; 7, Dining-room ; 8, Lavatory ; 9, Butler ; 10, Pantry ; 12, Servants' Hall ; 13, Kitchen ; 14, Larder, 16, Scullery ; 17, Dairy ; 20, 28, Coal ; 22, 23, Store ; 24, Loggia ; 26, Boots ; 27, 33, W.C. ; 29, 49, Bedroom ; 30, Dressing-room ; 31, Linen ; 32, Bath-room ; 48, Billiard-room.

(i.e., unsupported length) to give sufficient lateral stiffness? (3) What factor of safety should be used, and what shearing and bearing stresses for the rivets should be used? P.S.—What are the usual proportions for depth at centre and ends of fish-bellied crane girders?

(1) Let two weights, each equal to W and at distance l apart, pass over a girder of span L. Then, if the loads are both on the span, it can be shown that, at any point at distance y from one end of the girder, the B.M. will be a maximum when one of the loads reach the point. (See equations 5 and 8 on p. 189 of Andrews' "Theory and Design of Structures," putting W=W2=P=½W.)

$$\text{Then } M=\frac{W\left(y-\frac{l}{2}\right)(L-y)}{L}$$

$$\text{This is a maximum when } \frac{dM}{dy}=0$$

$$\text{i.e. when } L-2y+\frac{l}{2}=0$$

$$\text{i.e. } 2y=L+\frac{l}{2}$$

$$\text{or } y=\frac{L}{2}+\frac{l}{4}$$

i.e. when one of the loads at $\frac{l}{4}$ from the centre of the span, the other being on the other side of the centre.

$$\text{Then } M=\frac{W}{L}\left(\frac{L}{2}+\frac{l}{4}-\frac{l}{2}\right)\left(L-\frac{L}{2}-\frac{l}{4}\right)$$

$$=\frac{W}{4L}\left(L-\frac{l}{2}\right)^2 \quad \dots \quad \dots \quad (1)$$

If now only one load is on the span, the max. B.M. at any point occurs when such load reaches the point and the maximum

$$B.M.=\frac{WL}{2\cdot 4}=\frac{WL}{8};$$

this occurs when the load is on half the span. If this is equal to (1)

$$\frac{WL}{8}=\frac{W}{4L}\left(L-\frac{l}{2}\right)^2$$

$$L^2=2\left(L^2-Ll+\frac{l^2}{4}\right)$$

$$L^2-2Ll+\frac{l^2}{2}=0$$

$$2L^2-4Ll+l^2=0$$

$$\frac{L}{l}=\frac{4+\sqrt{16-8}}{4}=\frac{4+\sqrt{8}}{4}$$

$=1\cdot707$. (The + value is the only possible one. If therefore $l=\frac{L}{2}$, the maximum value will be given by equation (1) viz :

$$M=\frac{W}{4L}\left(L-\frac{L}{4}\right)^2=\frac{9WL}{64}$$

(2) Depth of girder may be the same as for ordinary plate girders, say $\frac{1}{10}$ to $\frac{1}{12}$ span. The breadth of the flange should be such that the compression flange may take the compression due to the B.M.+direct compression due to friction when pulled up by brakes. (This may be taken as ⅛ load on the wheels ; some authorities give .18 load.) Try breadth $=\frac{\text{span}}{30}$ and check back by Rankin's formula. This friction load should be allowed for in calculating the section as regards compression. (3) The question of factor of safety is a moot point. Theoretically for rolling loads the stresses should be about one-half those for fixed loads. I think that satisfactory stresses would be 5 tons per sq. in. for tension and 4 tons per sq. in. compression ; and for the rivets 4 tons per sq. in. in shean and 8 tons per sq. in. in bearing. The depth at the ends varies usually from one-half to two-thirds that at the centre. The consideration of getting a workable pitch of the rivets at the ends often really determines this in practice. A.

Board of Education Examination.

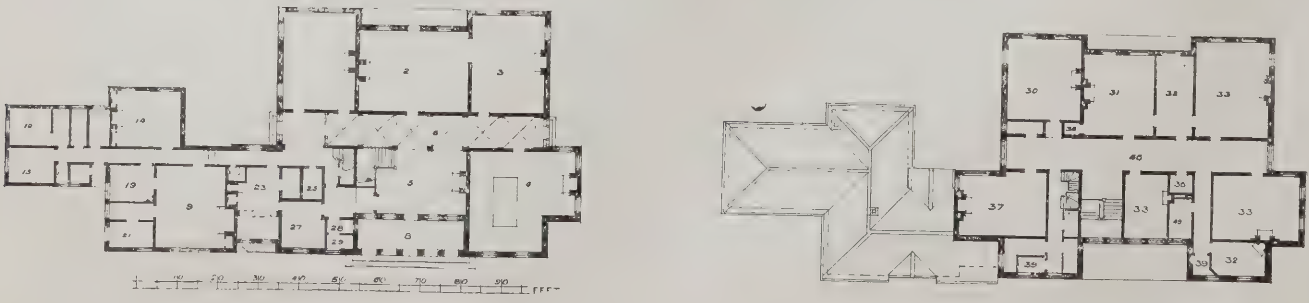
BRENTWOOD.—J. D. S. writes : "Are the answers to the Board of Education Building construction published ; if so, can you tell where I can get them?"

Answers to the papers set at the examinations of the Board of Education are not issued officially. The papers themselves are published by Messrs. Eyre and Spottiswoode, all the science subjects being issued in one publication, price sixpence. During 1903, however, complete, fully-illustrated, model answers to the building construction papers of the Board of Education set that year, appeared in the following issues of this journal, viz. : Elementary stage, May 20th ; advanced stage, May 27th ; honours stage, part I., July 8th ; honours stage, part II., September 23rd, and 30th. These numbers should certainly be referred to by our correspondent, as they indicate quite clearly the scope of the examination in each of the several stages. B. and B.

Withdrawing a Tender.

LONDON.—X. Y. Z. writes :—"A.B. is a builder who tendered for the erection of a house. He was pressed for time in making out his tender, and had to return the specification with the tender. Consequently he had not any further opportunity of going over the specification and checking his figures. His tender was found to be the lowest, and was accepted, and he signed the contract before checking his estimate. When he did so, he found that he had made a mistake of over £100, which would involve him in heavy loss. He has asked to be allowed to withdraw from the contract, and has proffered the difference between his tender and that of the next man, and £5 in addition to cover expenses. There is a penalty clause as to time."

A.B. is in a position of some difficulty. While a tender may be withdrawn at any time before acceptance (see "Emden's Building Contracts," 4th edn., p. 23), it cannot be withdrawn after that date. In a Scotch case, the principle of which is applicable in England, a builder made a tender to do certain work for £859. This tender was accepted. He afterwards found that, owing to a clerical error, the offer was £826 less than it should have been. In an action for damages for breach of contract, it was held that the building owner was entitled to succeed (Seaton Brick Co. v. Mitchell, 1900, 11 F. (5th ser.) 550 ; Ewing v. Lawson, 1900, 16 T.L.R. 140). Having regard to these cases, it seems that A.B. is committing a breach of contract. The measure of damages for the breach of a building contract has been said to be "the difference between the contract price of the work or building contracted for, and the cost of making the work con-



BUSSOCK WOOD, NEWBURY, BERKSHIRE. PLANS. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

1, Dining-room ; 2, Drawing-room ; 3, Library ; 4, Billiard-room ; 5, Hall ; 6, 46, Corridor ; 8, Entrance ; 9, Kitchen ; 10, 15, Coals ; 14, Servants' Hall ; 16, 29, 39, W.C. ; 19, Scullery 21, Larder ; 23, Butler ; 25, Store ; 27, Gun-room ; 28, Lavatory ; 30, Nursery ; 31, Study . 32, Dressing-room ; 33, Bedroom ; 37, Night Nursery ; 49, Bathroom.

ırm to the contract, plus the loss of earn-
ıg power or uses during the delay." So
ı the present case, the damages recoverable
ill be the difference between A.B.'s tender
ıd the reasonable cost of carrying out the
ork in a similar manner. The building
wner will not be compelled to accept the
ervices of the builder whose tender was
ext on the list. With regard to damages for
elay, these may be assessed at the actual
amage suffered, or else at the amount re-
erred to in the penalty clause. If A.B. has
ecided not to do the work, his best course
ill be to give notice of the fact at once.
n such a case the building owner cannot
ile up the damages against the building by
elaying the employment of another builder.
hould an action be brought, a judicious
ayment into court may effect a saving of
osts. A.B. should consult a solicitor with-
ut delay.

BARRISTER.

Constructing Reinforced Concrete Floor.

CALCUTTA.—YOUNG ARCHITECT writes: "I
ave a number of small rooms, 16ft. by 8ft.,
n a building, and wish to make the floors of
einforced concrete constructed with round,
ron bars. Could you inform me how to cal-
ulate the depth of concrete required, also
he size and number of bars? What text-
ook would you recommend for showing
ow to take out the above-mentioned stresses
t various spans?"

In reply to our correspondent's inquiry as
o the calculation of reinforced concrete for
he floors of small rooms, we would recom-
nend him to obtain the R.I.B.A. rules for
alculations in reinforced concrete, issued in
ı report some time ago, and obtainable from
he Royal Institute of British Architects, 9,
Conduit Street, W. We would also suggest
hat our correspondent obtained "Reinforced
Concrete," by Messrs. Marsh and Dunn,
ublished by Archibald Constable and Co.,
Ltd., London, price 31s. 6d.; or "The Prin-
iples of Reinforced Concrete," by Turneaux
ınd Maurer.

Acoustics.

BIRMINGHAM.—A. C. H. writes: "I am interested in the contemplated erection of a building to be used primarily for a dining hall, but also as a concert and lecture hall. The provision of a building for dining purposes presents little or no difficulty, but as a concert hall there is the all-important factor of acoustic properties. Many buildings have been erected with the aid of expert advice and in accordance with what the science of acoustics has to teach, which in the end have proved unsatisfactory for the rendering and hearing of music. Not unnaturally I feel it very desirable at the outset of a project to build such a hall to obtain some knowledge with regard to recent buildings in the country erected for a similar purpose and at not too great a cost, and I should be glad if you could inform me: (1) Who are the leading experts on acoustics as applied to buildings, who might be consulted if desired by the owners of the hall. (2) What and where situate are the large buildings put up in recent times that will fulfil the foregoing conditions and what is the opinion held of their acoustic properties. (3) Any suggestion which you could offer as the solution of the above problem would be appreciated."

The subject is a vast one and the fund of information of the slightest. You should obtain "Sound in its relation to Buildings," by H. W. Burrows, F.G.S., reprinted from the journal of the R.I.B.A., and obtainable at 9, Conduit-street, London, W., price 1s. In reply to the detailed questions: (1) I know of no professed expert on acoustics; but Mr. H. H. Statham, F.R.I.B.A., or Mr. E. A. Rickards, F.R.I.B.A., might be consulted as to the musical properties of concert halls. (2) The Aeolian Hall, Bond-street, London, is believed to be very satisfactory, also the Queen's Hall, Langham Place, W., the Philharmonic Hall, Liverpool. (3) A perusal of the paper previously referred to will probably prove helpful. The question is too wide for a detailed reply here.

Writing Specification.

EXETER.—J. S. writes: "What would be a fair charge for writing a specification for a large secondary school (304 places), contract price about £9,500? The specification included preliminary and general, all trades, and heating, lighting, etc., as well as tar-paved yards, tennis courts, boundary fences and approach roads, and runs to many pages of closely typewritten matter. By writing, I mean preparing the draft, the actual type-writing was done out. An early reply will oblige."

The number of pages in the specification, which would have afforded some clue to the amount of detail given, is unfortunately omitted in the query, but if a fully detailed specification such as might serve the needs of the quantity surveyor and contractor is intended, and not an outline specification accompanying a competitive scheme, a fair charge would be about ½ per cent. upon the cost of the work, unless of course the querist has also prepared the quantities when he might accept less if he is paid the full 2½ per cent. for quantities.

G.

Indoor Bowling Saloon and American Bowls.

PLYMOUTH.—H. W. writes: "Will you kindly advise me as to materials and construction for the floor of an indoor English Bowling Saloon. Also American bowls."

I do not quite know what is meant by an indoor English bowling saloon unless it is the old "skittle alley," in which the game of skittles or "nine-pins," known in olden times as kails, is played. I cannot trace any rules of the game governing the width of the alley, but suggest 4ft. wide as being suitable for the track. A square mitred

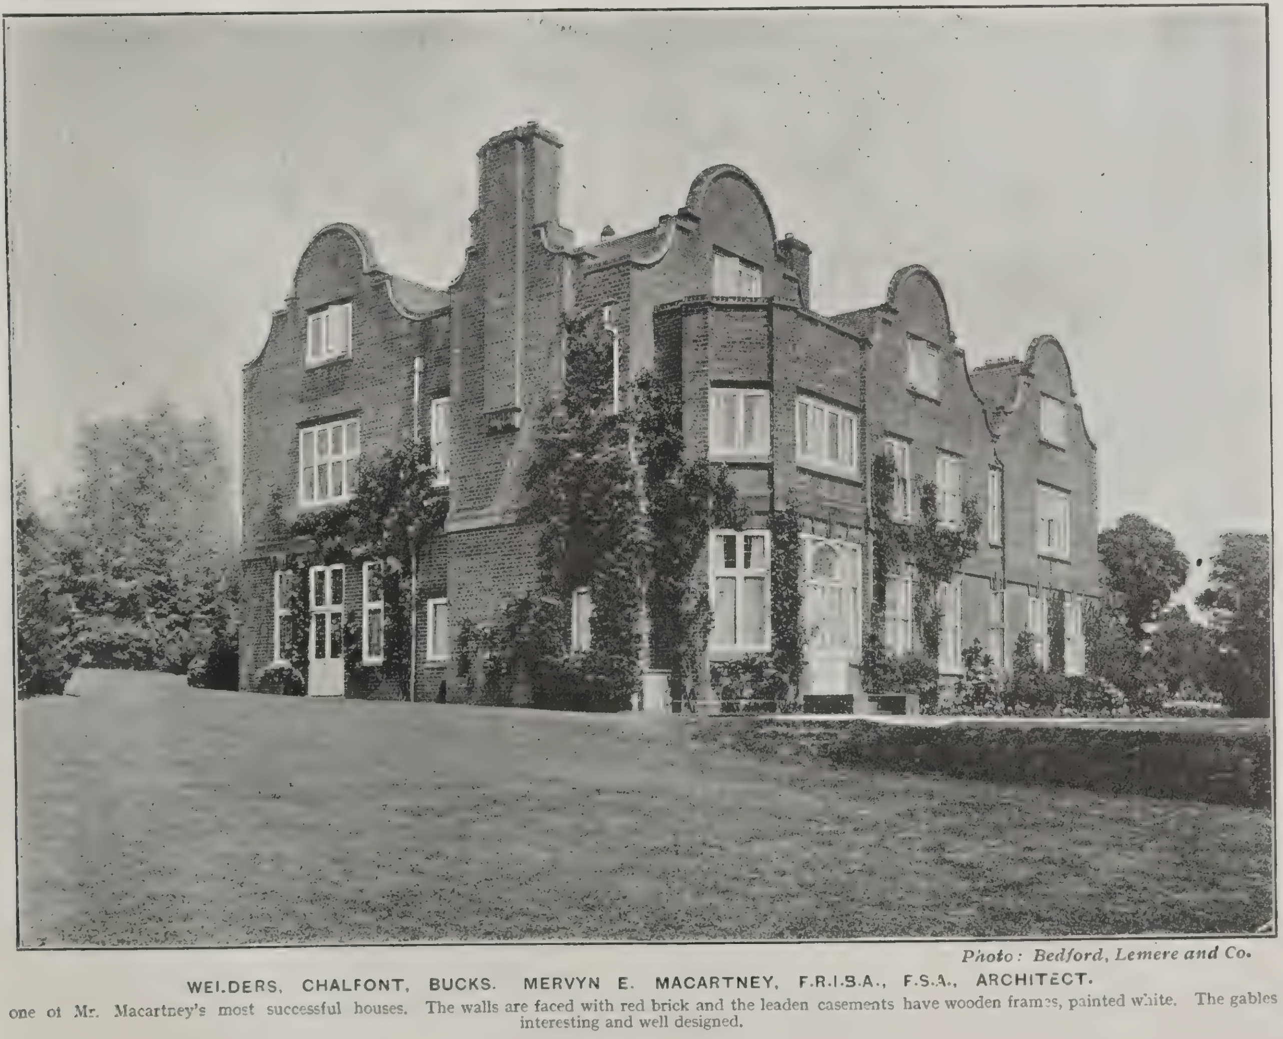

Photo: Bedford, Lemere and Co.

WELDERS, CHALFONT, BUCKS. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This is one of Mr. Macartney's most successful houses. The walls are faced with red brick and the leaden casements have wooden frames, painted white. The gables are very interesting and well designed.

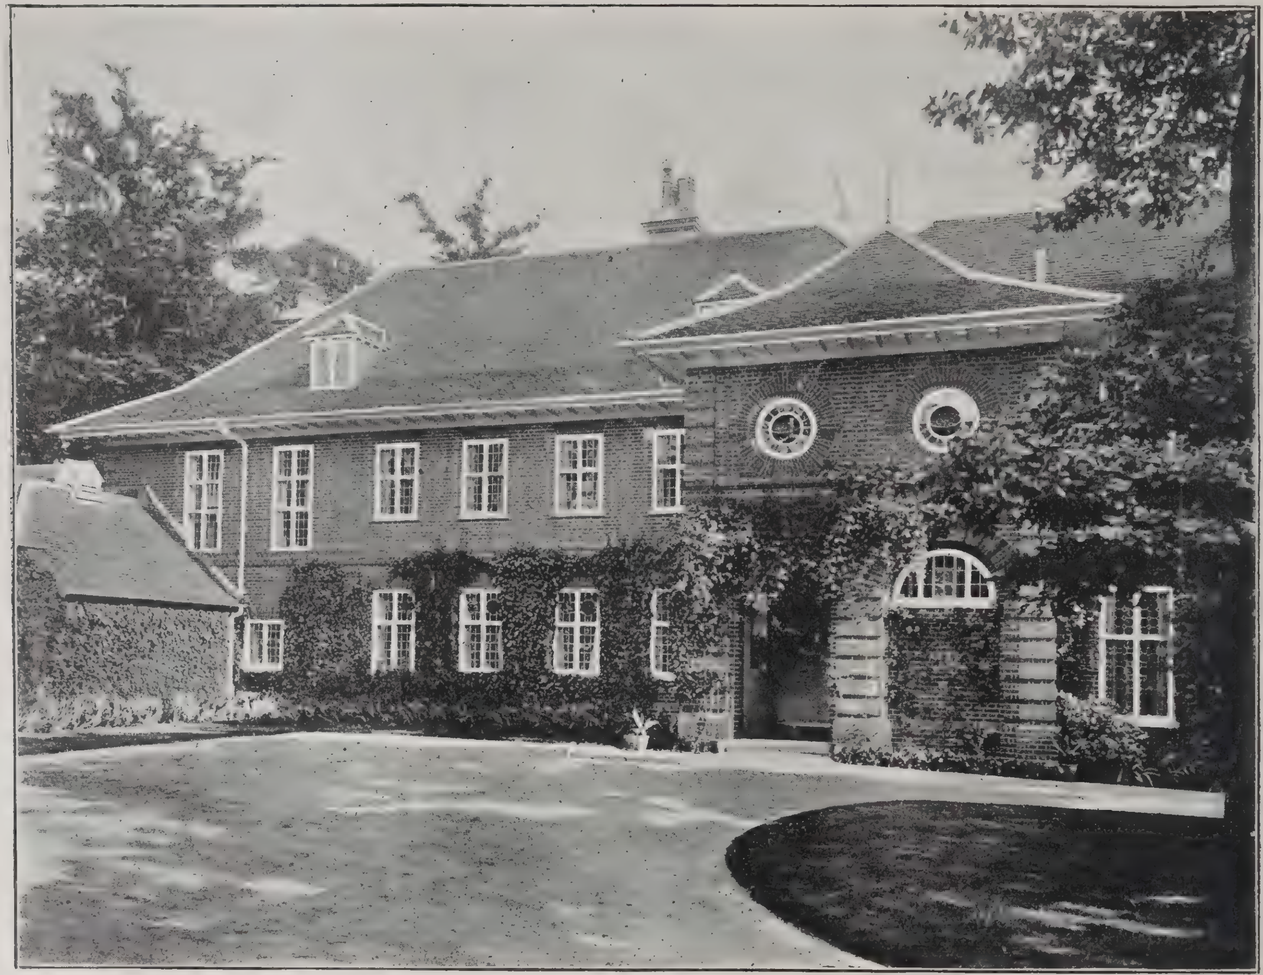

Photo: Bedford Lemere and Co.

FRITHWOOD HOUSE, NORTHWOOD. ENTRANCE FRONT. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

This is a quiet Georgian house, faced with red brick and roofed with red tiles. It is modelled on very simple and effective lines.

frame is let in flush with the flooring at one end, so that one diagonal lies along the centre line of the alley, in which the pins, about 12in. long and weighing from 7lbs. to 9lbs. each are set up. The length should be sufficient to allow 21ft. from the bowling point to the nearest pin. On one side of the alley an inclined wooden trough should be formed to enable the balls to be returned by gravity to the throwing point. The slightly flattened spherical balls are made of lignum vitæ, and weigh from 10 to 14lbs. each, so that some hard wood should be used for the floor such as maple, 2in. thick, in widths of about 4ins. and with the joints longitudinal with the alley. An oak kerb, 3in. by 6in., should be formed on either side to keep the balls within bounds, and a timber screen about 2ft. high around the end. The game of American bowls resembles skittles, and the general construction of the alley is the same. The game is played with ten pins instead of nine, the alleys are 60ft. in length by 4ft. wide. The pins are set up in the shape of an equilateral triangle with the apex towards the player, and the frame or "platform" should be shaped accordingly. The rules of the game are given in "The Modern Pocket Hoyle," New York.

Henry Adams.

Some improvements are being effected at the Guildhall, London. The coat of paint on the pillars of the hall is being removed, and the crypt has had the masonry walls cleaned and electric light installed.

* * *

Mr. Edward White, Vice-Chairman of the London County Council, who has been selected as the Unionist and Tariff Reform candidate for the Radcliffe-cum-Farnworth Division of Lancashire at the next General Election, is a native of Marylebone, where he was born in 1847, and where he carried on for many years the business of a builder.

* * *

Earl Wemyss has written to the Press concerning his proposal for the representation in the House of Lords of National Trading and other societies and institutions. The proposal has been well received by a number of important bodies, among them the following: Royal Institute of British Architects, Royal Academy of Arts, Society of Authors, Building Trades Federation of the United Kingdom, Society of Engineers, Gas Companies Association, London Chamber of Commerce, Machinery Users' Association, Royal College of Physicians, Railway Companies Association, Royal Sanitary Association, The Shipping Federation, The Surveyors' Institute, The Employers' Parliamentary Council (representing 30 Central Associations connected with the chief industries of the United Kingdom). The proposal is embodied in the two following resolutions which Earl Wemyss is to move in the House of Lords, which will, he believes, if adopted, make that House representative of "the organised brains of the nation, irrespective of party." The two resolutions are as follows:—(1) That in the opinion of this House, it would be for the public good that important national trading and other representative societies should each name three members of the existing Peerage, in the current and each succeeding Parliament, to speak and act on behalf of such societies on all questions in which they are interested, and that the names of the Peers so nominated be entered in the Journals of the House. (2) That the Lord Chancellor, the Marquess of Lansdowne, the Earl of Crewe, and the Earl of Halsbury be empowered to determine what societies are of sufficient importance to be admitted to the said privilege of nomination.

Mr. W. R. Hearn, the British Consul-General for San Francisco, reports that the rebuilding of the city made steady progress during the past year. Over £7,000,000 was spent in buildings and alterations, and the new structures in the business part of the city are immeasurably better than those which were destroyed. Plenty of hotel accommodation has been provided, and more travellers can be housed than before the disaster. The Chinese portion of the city, which was formerly a nucleus of filth, is now a model of cleanliness. The suburbs of San Francisco have profited immensely by the disaster, which settled a large population among them. The residents in these districts have accomplished great results by their concerted action. They have, generally speaking, pushed along street improvements, artificial lighting, street railways, and all other necessaries, so that the suburbs, which develope so rapidly, are places of comfortable abode supplied with all the conveniences of older residential districts.

* * *

A series of experiments have been carried out at the Arthur D. Little Laboratory of Engineering Chemistry, Boston, Mass, to demonstrate to what extent the burning of illuminating gas increases the amount of sulphur gases while ventilation is maintained at the usual standard of air purity. The result has been to show that the sulphur dioxide is absorbed by the plaster, and the greater the sulphur dioxide content the quicker the rate of absorption. The action continued even when the plaster was covered with paper, but less rapidly. The sulphur is quickly absorbed at the surface, and it is stated that a ceiling 10ft. by 8ft. will neutralise for some centuries the sulphur products produced by burning 25 c.f. of gas per day when the gas contains 20 grains of sulphur per 100 c.f.

ARCHITECTS OF THE DAY III. MR. MERVYN E. MACARTNEY, B.A., F.R.I.B.A., F.S.A.

Sketched from life by our Special Artist.

LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

Buildings in Progress and Completed.

ABERTILLERY. — The Trustees of Powell's Tillery Institute, Abertillery, are contemplating the addition of a swimming bath to their gymnasium, and Mr. F. R. Bates, architect, of Newport, has been consulted on the matter.

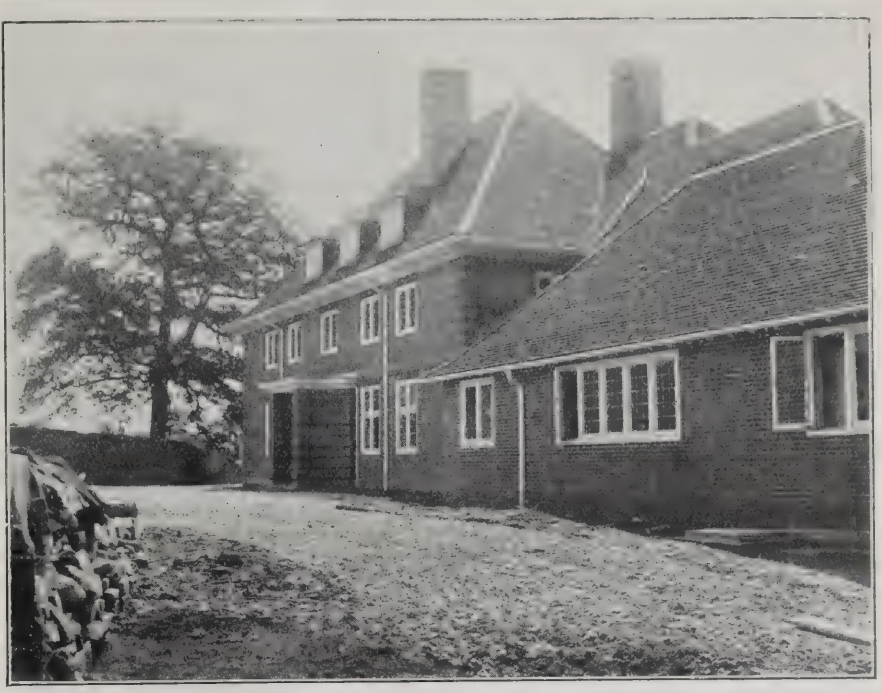
AUCHTERDERRAN.—A new church and hall are now being erected here. The church is to seat 450 persons, and the hall, which, owing to the sloping character of the site, is to occupy a position under the church, will accommodate 80 persons.

BORDESLEY GREEN, BIRMINGHAM. —The cost of a new police station, which was recently opened here, has been about £10,000. The building was designed by the City Building Surveyor, Mr. A. W. Lee, and was erected by Messrs. Thomas Elvins and Son, Soho Hill, Handsworth.

BRADFORD.—The Corporation baths and wash-house, now nearly completed, comprise three swimming baths—a first and a second class for males, and a separate one for females. The estimated cost is £39,715.

BRIGHOUSE.—The foundation stones of a new secondary school for girls has been laid. The school, which has been designed by Messrs. Sutcliffe and Sutcliffe, of Hebden Bridge, and which is a three-storey building, will provide accommodation for about 150 day scholars and 400 students in the technical evening classes, and is to cost £10,000.

CAMBUSBARRON, NEAR STIRLING.—A new United Free church, the memorial stone of which was laid recently, will cost £1,600. Mr. Ronald Walker is the architect.

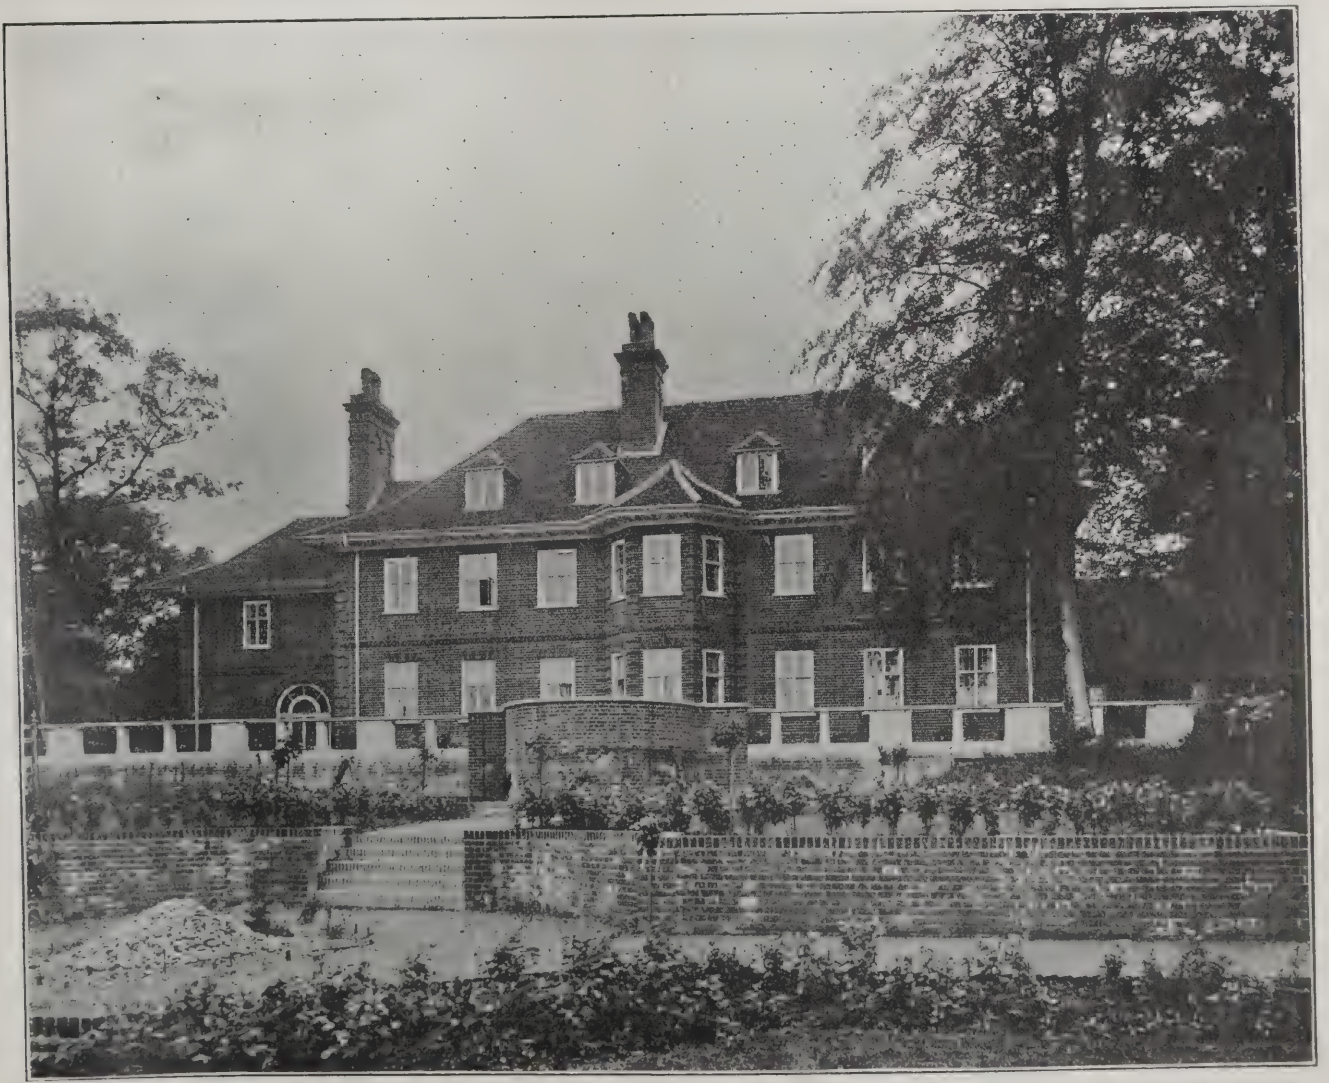


MR. MERVYN MACARTNEY'S NEW HOME, WOOLHAMPTON, BERKSHIRE. ENTRANCE FRONT.

This house is built of two-inch local red bricks, with Bath-stone dressings, and old tiles have been used for facing walls and roofing. The casements on this front have deal frames.

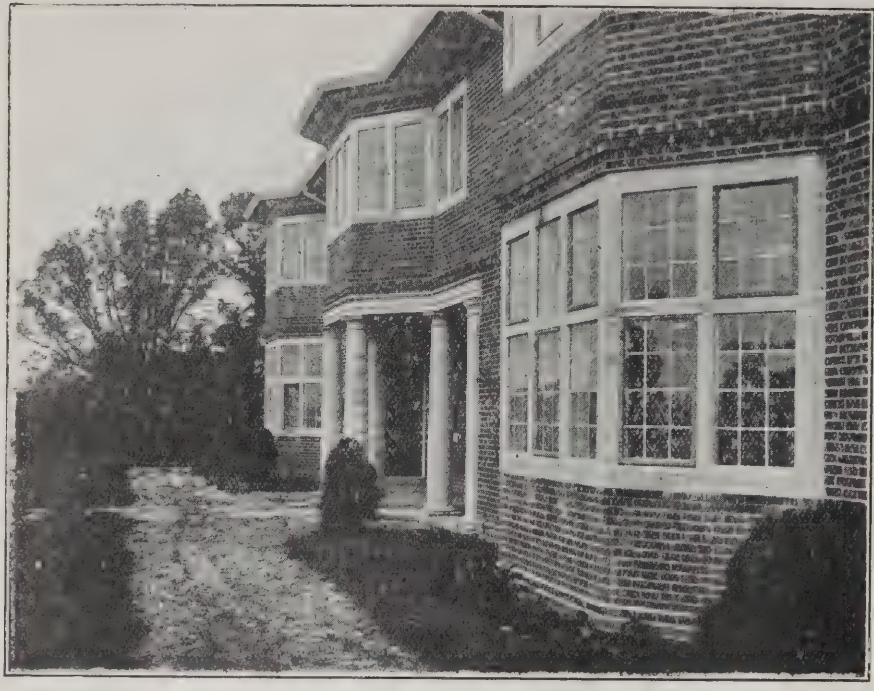
CONONLEY, NEAR SKIPTON. — The new institute now in course of erection is estimated to cost about £550. Messrs. R. B. Broster and Sons, of Keighley, are the architects.

DUDLEY.—The site of a new high school for girls has been purchased from the Earl who takes his title from this town, at a cost of £4,280. The total outlay, including the furnishing, is estimated at £23,000. The



FRITHWOOD HOUSE, NORTHWOOD. GARDEN FRONT. MERVYN E. MACARTNEY, F.R.I.B.A., F.S.A., ARCHITECT.

Mr. Macartney is one of the pioneers in the modern architectural planning of gardens. The garden of this house is a very good example of his work. It is laid out on a sloping piece of ground, two brick terraces with pleasantly arranged steps are placed in front of the house, and in the axial line is a wonderful bower of roses trained in a quite Oriental fashion, with flower gardens all round and a fish-pond at the side.



MR. MERVYN MACARTNEY'S NEW HOME, WOOLHAMPTON, BERKSHIRE. GARDEN FRONT.
This view shows the garden front with its loggia. The house being barely completed, and the garden only just laid out, the view is at present somewhat bare. The windows on this front have stone frames and iron casements.

school, which will accommodate 350 pupils, has been designed by Mr. J. Hutchings, architect to the Staffordshire Education Committee.

EDINBURGH.—The Dean of Guild Court have granted a warrant for the execution of various alterations to the Cathedral Church of St. Giles. Mr. R. S. Lorimer is the architect for the alterations, which include the construction of floors in reinforced concrete.

FINGHALL.—A new Wesleyan chapel to accommodate 100 people has been built here at a cost of £510. Mr. J. Dougill, of Aysgarth, is the architect.

GAINSBOROUGH.—A new scheme of Primitive Methodist church building, which will cost about £4,000, is now in hand. The church, now being erected, is in a plain Gothic style, designed by Mr. H. Harper, of Nottingham.

HANWELL.—The foundation stone of the new Church of St. Mellitus, which has been designed by Sir Arthur Blomfield and Sons, was laid recently by the Bishop of Kensington.

KEMBERTON.—The new tower, which has been added to the parish church, has cost £2,100. Among the interesting relics of the church is a Sarum chalice, dating back to 1520.

LONDON (BATTERSEA).—Accommodation for 20,000 volumes is given in the new library which is being erected at the south-west corner of the Polytechnic. Mr. F. Dare Clapham, F.R.I.B.A., the architect, has kept the design generally on the lines of the existing buildings. The cost will be about £6,000.

LONDON (CHELSEA).—The re-erection of Crosby Hall is to be immediately proceeded with. The four cottages in Danvers Street are to be demolished, and preparations made for rebuilding the old City hall. This has been made possible by the anonymous donor who contributed £5,000 towards the cost of re-erecting the hall, and promised a further £5,000 towards the general scheme of More House directly Crosby Hall was on the site. The donor has waived the latter condition, and is to provide the £10,000 immediately. Negotiations between the Council and the promoters of the scheme have resulted in an arrangement that the hall shall be open to visitors every morning and afternoon, the Council reserving the right to adjust the hours from time to time as may be found necessary.

MARCH.—The new County Council buildings opened here recently have been erected in the Georgian style. In addition to the various suites of offices, there is a roomy Council chamber, which seats 56 Councillors. A gallery across the end of the chamber provides accommodation for 100 persons. Mr. Herbert J. Green, A.R.I.B.A., of Norwich and King's Lynn, is the architect, and Mr. Reuben Shanks, of Chatteris, the builder whose tender of £4,295 was accepted.

MELROSE.—Building operations upon the new parish church which has been designed by Mr. J. M. Dick-Peddie, of Edinburgh, are now proceeding. The church, which, with hall and offices, is estimated to cost £9,000, is to replace the one destroyed by fire in June, 1908. The spire, originally built in 1810, is being utilised in the new design.

SHANKLIN, I.W.—The Grand Pavilion which has been erected on the pier at a cost of £4,000 provides seating for 700 people. The architect was Mr. Lewis Colenutt, and the builders were Messrs. Thorne and Co., of Westminster, who originally built the pier some 20 years ago.

WINNIPEG.—We learn that a new warehouse building is to be erected here at a cost of $75,000 (£15,411). The structure will be a seven-storey block on a site 100ft. by 50ft., and will, in all probability, be built in concrete.

Correspondence.

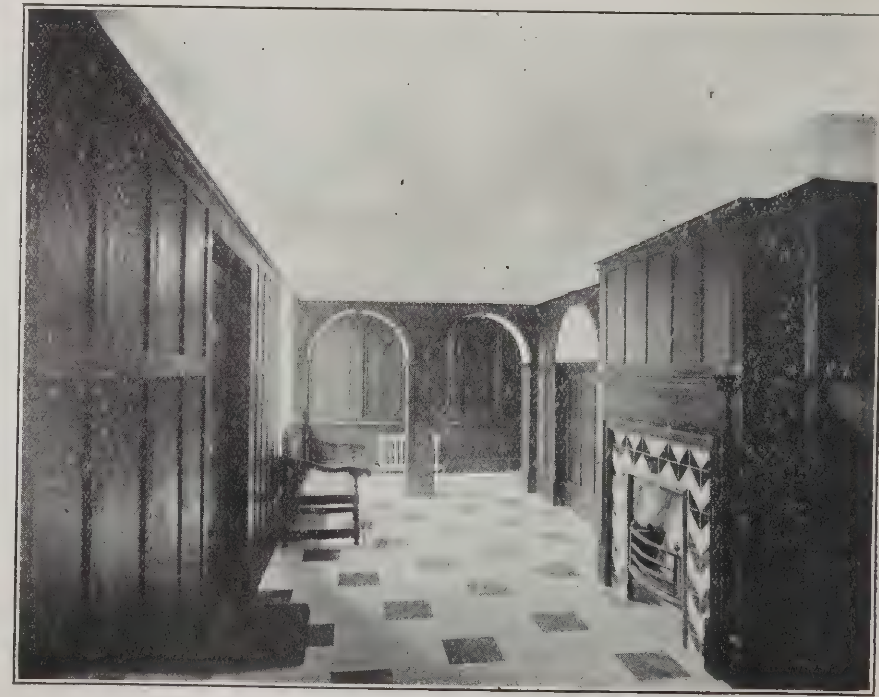
Steelwork Design.

To the Editor of THE BUILDERS' JOURNAL.

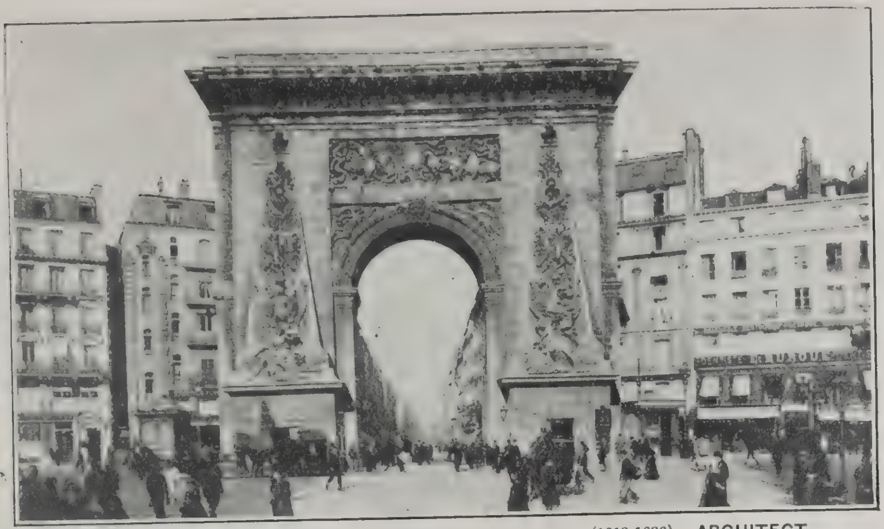
SIR,—I enclose a note on the answer to "Edinburgh" in a recent issue of "The Builders' Journal" [see Enquiries Answered.]

Having had to design some hundreds of bridges, and probably some thousands of girders, I have been frequently struck with the wide difference between the methods of girder design as explained in nearly all text books and the methods practiced by railway companies and large engineering manufacturing firms. Speaking from memory, I believe that Tarn's old method of dome calculation owes its simplicity to its neglect of hoop stresses; and any method which does that fails to explain the apparently marvellous stability of the old Spanish and modern American thin shelled domes. At the structural mechanics class at the Central School of Arts and Crafts (Architectural School), I endeavour to prove all these abstruse points by practical experiments and so far as we have gone the accuracy of Mr. Dunn's deductions have been completely borne out. The description of the design of Westminster Cathedral by Mr. Marshall in the A.A. Journal, May, 1907, contains frequent references to the difficulties caused by the weight of the domes, and the extent to which Mr. Bentley's original ideas were modified thereby. These domes which are of great (and to my mind quite unnecessary) thickness were apparently designed as simple arches by Tarn's method, the enormous additional stability afforded by the hoop stresses being neglected.

Yours faithfully,
PERCY J. WALDRAM.



MR. MERVYN MACARTNEY'S NEW HOME, WOOLHAMPTON, BERKSHIRE. THE HALL.
The walls are lined with oak, taken from his cottage at Silchester Common, eked out with some old Dutch panels, remaining from a stock that was partly used in the billiard-room at Frithwood House, Northwood, which house is illustrated on pages 114 and 115. The floor is paved with squares of Irish green and bastard statuary marbles. The staircase, formerly at 28, Margaret Street, London, is illustrated in the "Architectural Review" for August.



PORTE ST. DENIS, PARIS. FRANCOIS BLONDEL (1618-1686), ARCHITECT.

This triumphal archway was erected by Louis XIV. in commemoration of his campaigns in Flanders and the French Comté. It is over 80 feet high. The sculpture was designed by Girandon and executed by Michael Auguier and his brother.

PORTE ST. DENIS, PARIS.

This triumphal archway, raised in celebration of the successful campaigns conducted by Louis XIV. in Flanders and the French Comté, is remarkable both for the simplicity of its architectural treatment and for the elaboration of the decorative sculpture with which it is enriched. It is interesting to note that the architect of this fine monumental work, Francois Blondel (1618-1686), like Pierre Lescot, the first architect of the Louvre, and Claude Perrault, the author of a much admired addition to that great building, devoted his youth neither to the study of the arts nor to the practice of architecture.

Blondel indeed had acquired a considerable reputation as a scholar and mathematician, when he was appointed, in 1652, tutor to the son of Henri Auguste de Loménie, in whose company the future architect travelled in Germany and Italy, for the ensuing three years, during which many places of architectural interest were visited and studied. On his return to France, Blondel appears to have been entrusted by the King (Louis XIV.) with the conduct of certain political negotiations which not only necessitated his attendance at the courts of various contemporary European sovereigns, but involved on occasions visits to Constantinople and Egypt. Later, as a reward for the general success of his diplomatic missions, Blondel was appointed teacher of mathematics to the Dauphin, and was honoured by being elected to a professorship at the Royal College in Paris. There is no reason to doubt that the unique opportunities afforded by his travels enabled the future architect to carefully examine and study the most celebrated buildings of antiquity, and the architectural knowledge he thus obtained had a marked influence on his subsequent career.

But although Blondel thus grew more and more deeply interested and engrossed in the study of architecture yet, for some considerable time, there appeared to be but little prospect of his finding employment in the active exercise of that art. However, his opportunity came at last, when, in 1665, at the mature age of forty-seven, he received the King's commands to rebuild the massive stone bridge which crossed the river Charente in the town of Saintes. This bridge having been reconstructed in a thoroughly satisfactory manner, the King showed his appreciation of the services rendered by his architect by decreeing, through the issue of letters-patent, that for the future all public buildings about to be erected in Paris were to be arranged in strict conformity with a general plan prepared by Francois Blondel.

We next hear of Blondel in connection with the gateway, built by Henry II., at the end of the Rue Saint Antoin in Paris, which in 1672, was apparently badly in need of enlargement and restoration. Under Blondel's directions two additional arcades and an attic storey were added to the old structure, but the gateway thus enlarged was demolished about a hundred years later.

By a singular fatality another monument of the same kind, also erected in Paris by Blondel, and known as the Porte Saint Bernard, experienced a similar fate, as it was destroyed in 1792 on the ground that it obstructed the growing traffic of the streets.

However, there can be little doubt that the experience gained by the architect in reconstructing these two gateways was of great service to him when he was called upon, at a later period, to erect the greatest structure of its kind that had ever been up to that time produced by modern architects, or, perhaps, even by those of ancient times, for it is doubtful whether, of all the triumphal arches erected in honour of the Roman Emperors, there was one which was raised so high as the gateway of St. Denis, Paris.

Situated between the Rue du Faubourg, St. Denis on the left, and the Rue St. Denis, one of the oldest streets of Paris, on the right, Porte St. Denis comprises a large single archway which forms the central feature of a square structure over eighty feet in height. Its two facades differ only in regard to the amount of decorative work with which they are respectively embellished, that facing the Rue du Faubourg being treated in a somewhat less ornate manner.

The faces of the huge piers which form the abutments of the archway are relieved by obelisks placed upon square shaped pedestals and surmounted by globes.

The fronts of the obelisks are covered with trophies, designed in the antique manner and extending the whole height of the obelisks. Beneath each trophy, of the front or south facade, is a colossal seated figure in full relief, that on the left representing Holland vanquished, and that on the right the river god of the Rhine. On the north facade two lions take the place of the figures. The pedestals are pierced with small openings for pedestrians, round which are low reliefs of ancient arms of warfare. Above the central archway there are sculptured representations (in bas relief) of the passage of the Rhine by Louis XIV. in 1672, and of the capture of Maastricht (1673) and on the frieze the words *Ludovico Magno.* The whole of the sculpture was designed by Girandon, and executed by Michael Anguier and his brother.

The author of this fine effort of design, who was no mean authority on monumental and stately buildings, regarded his Porte St. Denis as one of the greatest constructions of its kind in the world, and he states that he "endeavoured to make its appearance even more considerable by means of an extreme justness of proportions in its ensemble, and between its parts, rather than by the quantity of ornaments with which it could be covered."

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Aug. 30	FOREST HALL, Elementary school for 250 scholars. County of Northumberland Education Committee invite designs from architects practising in the County and in the City and County of Newcastle-on-Tyne. Particulars, conditions and plan of site from C. Williams, Secretary to the Education Committeé, The Moot-hall, Newcastle-on-Tyne.
Aug. 31	HUDDERSFIELD NEW CHURCH. Plans are invited for a church to seat 400, to cost about £2,000, not to exceed £2,500, with all fittings, furnishings, lighting and heating apparatus. Plans to be forwarded to the Rev. D. Macræ Tod, B.D., St. James' Manse, Huddersfield, by Aug. 31.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.
Oct. 11.	HULL TRAINING COLLEGE for teachers in Elementary schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.

Obituary.

Mr. William Owen, A.R.I.B.A.

We regret to announce the death of Mr. William Owen, of Duchy Chambers, Clarence Street, Manchester, which took place at Surbiton on August 6th. Mr. Owen, who was a son-in-law of Sir Charles Scotter, went the previous week to pay him a visit at his residence, Rutland House, Surbiton, Surrey, where he was taken ill. Mr. Owen, who was born in Altrincham in 1852, studied at the Manchester School of Art, and in 1874 was awarded a gold medal by South Kensington for the best architectural design of the year. He was afterwards elected an associate of the Royal Institute of British Architects, and has since carried on an important practice in Manchester and district. He was one of the first members of the Hale Urban District Council, and in 1903 was appointed to the chair. He was until the time of his death a member of the council.

* * *

The death took place suddenly on July 23 of Mr. James Thompson, head of the firm of Thompson and Brierley, builders and contractors, Bury. Deceased, who was 74 years of age, was apparently in his usual health. Amongst big contracts carried out by the firm have been the Bury Art Gallery and Library, Bury Markets, council schools at Failsworth and Heywood, churches at Walmerslay and Hawkshaw, and banks at Bury and Rochdale.

LISCARD PUBLIC LIBRARY.

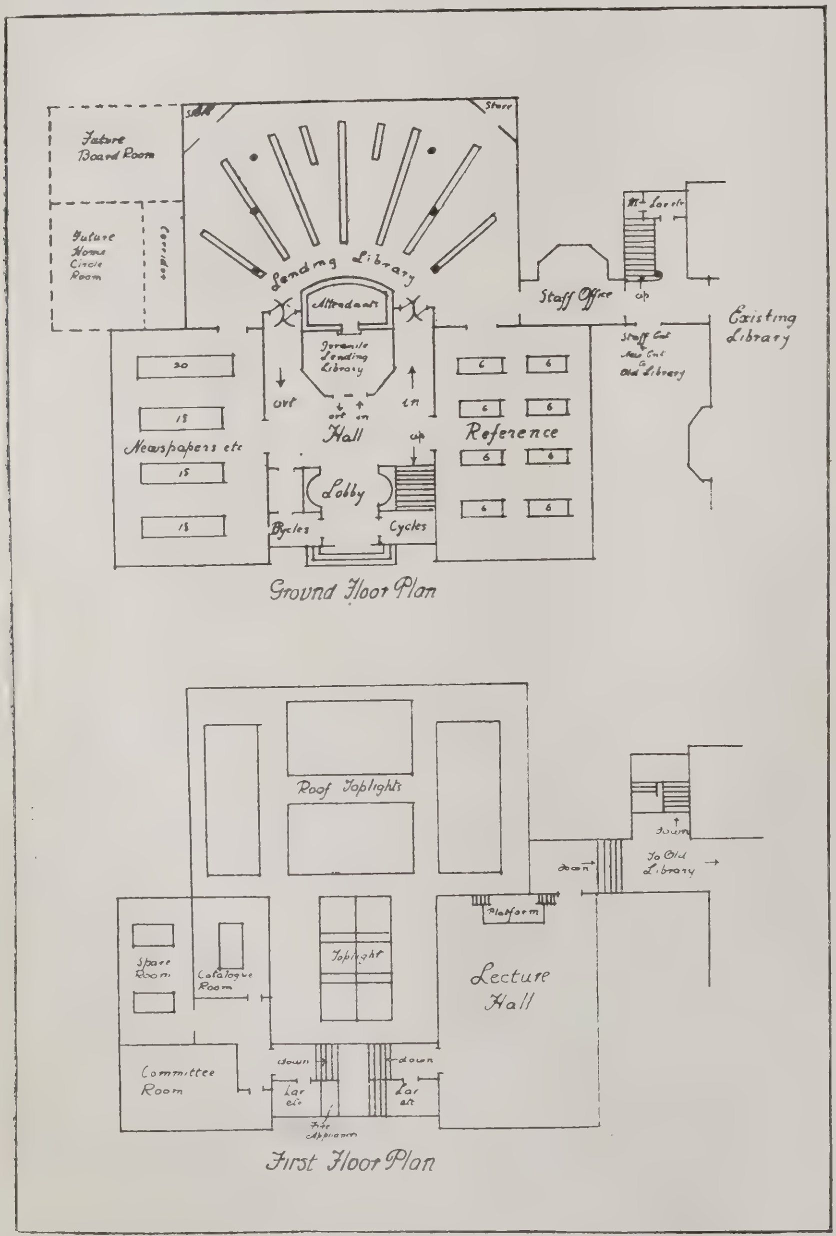
Competitive designs were invited from architects practising in the counties of Lancashire and Cheshire, premiums of fifty, thirty, and twenty pounds being offered for those designs placed respectively first, second and third by the assessor. With regard to the latter arrangement, Mr. G. H. Willoughby, F.R.I.B.A., of Manchester, who acted in the capacity of assessor, advised the Library Committee to reconsider their proposal and award to the five competitors, whom Mr. Willoughby bracketed second, premiums of twenty pounds each. The conditions of the competition, for which we believe the Library Committee to be responsible, appear to us to be somewhat unnecessarily loaded with explanatory detail, though doubtless it is better to err on this side than on that of insufficiency. At the same time we do not regard it as altogether desirable to have gone so far as to have provided a possible solution of the whole problem in the shape of a suggested sketch-plan, even though this diagram was "not given with a view to literal reproduction, but as a convenient method of indicating the provision required, and as showing the desired inter-relation of the main rooms." The greater number of the competitors, having once seen this arrangement so thoughtfully provided, appear to have been obsessed with the recollection of it, and quite unable in consequence to attempt even the smallest variation in detail. On the ground floor the accommodation required included an adult lending library, a juvenile lending library, a central hall and entrance lobby (with provision for porter and bicycles), a newspaper room, a reference library, and staff and lavatory accommodation. On the first floor a catalogue room, a committee room, a spare room, lavatories and a lecture hall were to be provided. The whole arrangement of rooms was to be connected by means of a short length of two-storied corridors to the existing library, and provision made for future extension on the site if necessary. The total cost of the new block was to be limited to £7,000, this being held to include drainage, heating, ventilation, lighting, lift, etc., but not movable furniture and fittings, or architect's fees, etc. It was requested that each set of plans submitted should comprise the following:—A block plan to a scale of 20ft. to one inch, showing proposed drains, road, paths, and entrances; a plan of each floor to scale of 8ft. to one inch, showing internal fittings, such as bookcases, counters, etc.; cross longitudinal sections to same scale as plans; Imperial size perspectives in sepia or Indian ink were admitted, but all elevations were to be devoid of colour or shadows. No alternative scheme was admitted. The first premiated design, that of Messrs. R. B. Macoll and C. E. Tonge, of Southport, adopts the arrangement suggested by the Library Committee in its main features. The proportions of the reference library and the newspaper room are somewhat improved. With regard to the lending library, in consideration of the disposition of the stacks, it is perhaps questionable whether its rectangular shape is altogether satisfactory. In our opinion the most desirable shape in this case is undoubtedly the semi-circular, though the treatment of its external junction with the main block requires very careful solution. In this plan, as in all the premiated schemes, the open access system of distribution is adopted in a satisfactory manner, though we cannot but regret the cutting-up of the entrance hall by the rather unpleasantly polygonal juvenile lending library. On the first floor the planning of the administration block appears likely to work admirably. Perhaps the shape of the committee room would bear a little revision. With the elevations we must confess we do not find ourselves entirely in sympathy, though Mr. Willoughby, in his report, has pronounced their fenestration to be good.

The design of Messrs. Sproat and Warwick, 25, Lord Street, Liverpool, embodies, we think, most of the best points of those designs bracketed second, and others which have adopted the semi-circular treatment for the lending library, and for that reason we have selected it for reproduction. The incorporation of the children's lending library in the main library, although resulting in a somewhat cramped arrangement, leaves the main hall unencumbered, and incidentally gives more direct access to the lending library than is obtained in most of the designs submitted. The double staircase on either side of the main entrance, considered in its relation to the latter, is perhaps a trifle abrupt, and might conceivably result in congestion at that point on occasion. We cannot but commend, however, the ingenious forethought displayed in the provision of an additional bookstore, balancing the staff office on the opposite side of the lending library, and in the admission of light to the newspaper and reference rooms over those portions of the latter which would otherwise be deficient, by means of top lights, without detriment to the elevations. The working arrangement of the first floor, moreover, seems to us to give evidence of expert ability in this direction. The elevations are powerfully drawn.

Mr. J. R. Earnshaw, 4, Chapel Walk, Manchester, has also adopted the circular lending library in a manner suggestive of further possibilities, whilst Messrs. Deacon and Horsburgh, 12, St. George's Crescent, Liverpool, also offer several good points.

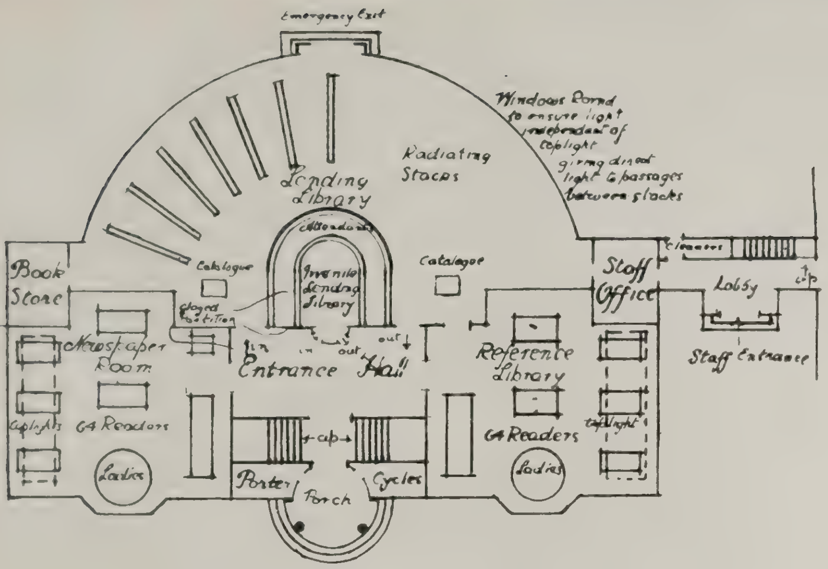
Messrs. Appleyard and Quiggin, with Mr. Beveridge, of Liverpool, present a solution which departs in a refreshing manner from the main lines of the suggested plan, in that the axes of the newspaper and reference rooms are at 45 degrees to the axis of the main lending library. Though this original method of handling the problem results in a thoroughly workable plan, we think it would be found to be somewhat expensive, and likely to offer insurmountable difficulties to successful elevational grouping. Quite extraordinary enthusiasm seems to have prompted Messrs. Packer, Drewitt and Drewitt to prepare interior perspectives of their scheme, which, though in many respects admirable, would seem also to be rather extravagant in others.

A carefully and neatly drawn set is submitted by Mr. D. Remmington, 41, North John Street, Liverpool. Also we note that Messrs. Newell and Dawson, of Liverpool, are responsible for a scheme in which the elevations are on the whole pleasantly and soberly designed in the early Georgian manner.

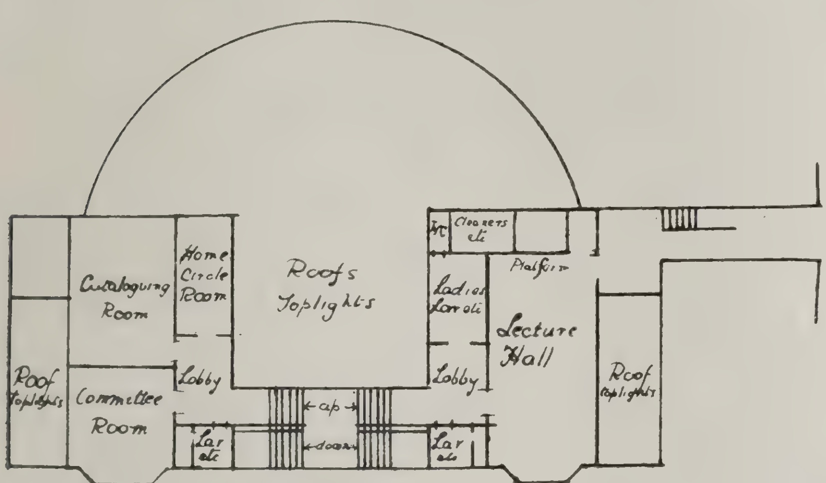


THE LISCARD LIBRARY COMPETITION. ROUGH SKETCH PLANS OF FIRST PREMIATED DESIGN. R. B. MACOLL AND C. E. TONGE, ARCHITECTS.

This design shows the adoption of the arrangement suggested by the Library Committee. In this plan, as in all the premiated schemes, the open access system of distribution is adopted in a satisfactory manner, though we cannot but regret the cutting-up of the entrance hall by the rather unpleasantly polygonal juvenile lending library. On the first floor the planning of the administration block appears likely to work admirably. Perhaps the shape of the committee room would bear a little revision.



Ground Floor Plan



First Floor Plan

THE LISCARD LIBRARY COMPETITION. ROUGH SKETCH PLANS OF DESIGN BY SPROAT AND WARWICK, BRACKETED WITH FOUR OTHER DESIGNS FOR SECOND PLACE.

This design embodies, we think, most of the best points of those designs bracketed second, and others which have adopted the semi-circular treatment for the lending library, and for that reason we have selected it for reproduction. The incorporation of the children's lending library in the main library, although resulting in a somewhat cramped arrangement, leaves the main hall unencumbered, and incidentally gives more direct access to the lending library than is obtained in most of the designs submitted.

BIRMINGHAM MUNICIPAL SCHOOL OF ART.

New Architectural Day School.

A Day School of Architecture has been founded at the Municipal School of Art, Birmingham. The object of the school is to provide architectural students in the Midlands with a thorough training in all the branches of their profession, and to prepare them for the examinations of the Royal Institute of British Architects. The course will be spread over four or five years. It is intended that the first two years shall be spent at day classes, and that they shall take the place of the first two years of articled pupilage. The latter two or three years will be spent at evening classes, and will run concurrently with articled pupilage. The fee for the day school will be 40 guineas per session, and that for the evening school 10 guineas. The committee have received an undertaking from a large number of prominent architects in the Midlands promising to forego the whole or a portion of the fee ordinarily received by them in the case of pupils who shall have attended the proposed school. The syllabus will be as follows: First year: Lectures on architectural history, building construction, elementary physics, and geometry; demonstrations and practical work in stone-masonry, carpentry, and bricklaying; simple planning, elementary design (doors, roofs, windows, etc.); perspective, drawing and lettering. Second year: Studies in ancient architecture, including measuring; practical work; lectures on the historic styles and on iron and steel construction, physics, etc., design. Third and fourth years: Mainly design and advanced physics and kindred subjects. It is hoped that third and fourth year students will be able to take some of their science subjects and carry out tests as to the strength of materials, etc., at the Birmingham University. The machinery and equipment possessed by the University for this purpose is quite unique. It is anticipated that students who follow the full course will be exempted from the intermediate examination of the R.I.B.A. A competent staff has been secured, and the first session will commence on September 13th.

The Belgian builders, now on a visit to this country, are to be entertained to dinner to-morrow, Thursday, August 12th, by the London Master Builders' Association. The dinner will take place at the St. Ermin's Hotel, Westminster, at 7 p.m.

Federation News.

LEIGH AND DISTRICT ASSOCIATION.

Secretary: S. Wigham.

On November 1st, 1908, six months' notice was given to the Operative Bricklayers of the following rule: "That on all jobs outside the Leigh Borough boundary an employer may engage the men on the job, providing such job is within the walking time radius of that particular town where the job is situated." After the six months' notice had expired the Operatives referred the rule to the Local Conciliation Board, where it was discussed at several meetings. The Operatives urged that the Leigh Master Bricklayers would, if this rule was adopted, give preference to the workmen in the town where the jobs were situated in preference to themselves. The Leigh Masters, however, pointed out to the Operatives that they were handicapped with jobs in Atherton and Tyldesley, which are just outside the three-mile radius from Leigh. Formerly, when the Leigh Master Bricklayers were doing a job in Atherton or Tyldesley and engaged men living in these places, these men would work under the walking-time rule belonging to the Leigh operatives, that is, they would begin work at 6.45 when the Leigh bricklayers arrived and booked their time from six o'clock. After several heated discussions on the subject, the operatives at length agreed to accept the rule if the masters would assist them in persuading their workmen to join the Trade Union if they had not already done so. This the masters agreed to on condition that the Trade Union bricklayers would try to preprevent the operatives from working for non-master bricklayers or doing jobs on their own at less than the day-work charges agreed to by the masters.

SOUTHAMPTON AND DISTRICT ASSOCIATION.

Hon. Secretary: A. T. Doggrell.
Asst. Secretary: S. J. Moore.

The long-standing disputes between the Southampton Master Builders' Association and the local operatives have for the present been settled by the award just issued by Mr. A. A. Hudson, the arbitrator appointed by the Board of Trade. The arbitrator sat for two days hearing evidence on both sides as to proposed alterations of wages and rules. The operatives' demands were an increase of 1s. per hour to all mechanics and various alterations of rules, these demands being met by the employers with counter notices of a reduction of ½d. per hour on all mechanics' wages and sundry alterations of rules. The net result of the award was as follows:—

Wages.—The wages of mechanics in all trades to remain as at present—no increase or decrease.

Working Hours.—A full week to consist of 53 hours full time in place of 56½ as before, the alterations being 6 a.m. to 5 p.m. on each day in the week except Saturday in place of 6 a.m. to 5.30 p.m. and 6 a.m. to 12 p.m. on Saturdays in place of 6 a.m. to 1 p.m.

Overtime.—Worked at employers request (not otherwise), to be paid at rate of time and a quarter from 5 p.m. to 7.30 p.m., time and a half from 7.30 p.m. to starting time next morning, under the old rules time and a quarter was paid to 7.30 p.m., time and a half 7.30 p.m. to 9.30 p.m., and double time from 9.30 p.m. to starting time next morning. All Bank Holidays to be paid time and a half (Good Fridays excepted). Double time to be paid on Saturdays after 7.30 p.m. and Sundays. Christmas Days to be paid for same as Sundays.

Generally.—Sundry other minor alterations were made, and an arbitration clause inserted as follows: "In case of any dispute arising between the employers and employed or between an individual employer and employee or employees, the secretary of the Employers' or Employees' Society or Association may give to the secretary of the other Society or Association a notice in writing of such dispute and thereupon 3 representatives of the employers shall meet 3 representatives of the employees to endeavour to settle such dispute, but failing settlement of such dispute within ten days of the date of the said notice the secretary of either Society or Association may apply to the Board of Trade to appoint an arbitrator whose decision shall be final and binding on both parties to the said dispute."

Societies and Institutions.

The Builders' Benevolent Institution.

The 62nd annual general meeting of the Builders' Benevolent Institution was held at 31 and 32, Bedford Street, Strand, W.C., on Monday, July 26th. The minutes of the last annual meeting were read and approved; the appended annual report, the audited accounts, and the amended rules were read and approved. The following elections were made:—President, Mr. Howell J. Williams, J.P., L.C.C.; treasurer, Mr. J. Howard Colls; committee, re-elected: Mr. C. Ansell, Mr. W. Brass, Mr. T. Hall, Mr. B. Hannen, Mr. H. Arthur Bartlett, Mr. H. Holloway, J.P., Mr. J. Randall, Mr. W. Shepherd, Mr. T. Stirling; elected: Mr. J. W. Lorden, Mr. F. G. Rice, Mr. J. C. Nicholson. Votes of thanks were given to Mr. J. W. Lorden for his kind and valuable services as president during the past year, also to the hon. auditors (Mr. J. T. Bolding and Mr. R. J. Ward, F.C.A.), the trustees, vice-presidents, committee, and dinner stewards.

The committee, in submitting their sixty-second annual report, deeply regret that in consequence of the continued depression in the building and allied trades the funds at their disposal have decreased to such an extent that they have been obliged to sell out £500 of stock to meet liabilities in the past year. The committee earnestly appeal for assistance in order to make provision for the many claims upon this charity. They desire to register their hearty vote of thanks to Mrs. Richardson for her kind gift of £857 in memory of her deceased husband. The money has been invested in the purchase of London and South-Western Railway Company Stock, and the proceeds will be devoted to paying a female pensioner, approved by the committee and nominated by Mrs. Richardson. Attention is directed to the fact that the greatest economy is exercised in keeping down the administrative expenses. During the year three (3) additions have been made to the pensioners' list, which now consists of 29 men and 27 women. Five (5) male and five (5) female pensioners have died during the last twelve months; the widows of the deceased male pensioners have been placed on the list after careful investigation of their claims. The committee desire to thank Mr. J. W. Lorden for his valuable services and kind contribution as president. Also the trustees (Mr. F. J. Dove, Sir Arthur C. Lucas, Bart., Mr. T. F. Rider, Mr. J. Howard Colls, Mr. T. Stirling, and Mr. J. T. Bolding), the honorary auditors (Mr. J. T. Bolding and Mr. R. J. Ward, F.C.A.), and the dinner stewards. Mr. Howell J. Williams, J.P., L.C.C., has kindly accepted the presidency for the coming year. The annual dinner will be held on Thursday, November 25th, 1909.

The National Association of Master House Painters & Decorators of England & Wales

The Sixteenth Annual Convention of this Association will be held at Sheffield from September 13th to September 18th, the headquarters being at the Artillery Drill Hall, Shoreham Street, Sheffield. The Convention will be opened at 7.30 on the 13th inst., when the President (Mr. James Puttrell) and Mrs. Puttrell will receive the members and friends. The following is the programme arranged for the Convention:—11: Reception of members and visitors by the President and officers in the Exhibition Hall, and Inspection of exhibits of manufactures, apprentices' competition work, and studies made in Italy by B. Hamlyn, Ivor Beaumont, and Tom Stoney, winners of the International Studentship competition. 11.30: Arrival of the Rt. Hon. the Lord Mayor of Sheffield and members of the Corporation, who will make an inspection of the Exhibition and apprentices' work. 12: The Lord Mayor will take the chair and welcome the visitors to the city. Address of welcome to the Convention and Presidential address by Jas. Puttrell, Esq. 12.30: Opening of the Exhibition by Sir Wm. Richmond, R.A., K.C.B.; votes of thanks. 2.30 (closed session): Reception of delegates from the Netherlands Association of Master House Painters, minutes of last Convention, report from the Secretary, report from the Treasurer, report from the Education Committee, report re the Travelling Scholarship Competition, report from the adjudicators of the Apprentices' Competition, report from the adjudicators of the Extension Prize Scheme Competition, votes of thanks to the adjudicators and examiners, greetings from the Association of Master Painters in Scotland (J. Carfrae, Esq., President) and Ireland (Ed. Gibson, Esq., President), trade topics to be introduced by members, report from the Paperhangings Committee, report from local Associations. All business held over will be taken at the morning session on Tuesday. Visit to the Town Hall and afternoon tea. 8: Lecture by Sir Wm. Richmond, R.A., K.B.C., on "House Decoration for the Masses." Wednesday, September 15th: Breakfast and Conference of Presidents and Secretaries of Associations, Royal Victoria Station Hotel, 7.30 to 9 a.m. Particulars to be announced later. All names of those intending to be present to be sent to the General Secretary not later than September 1st, 1909. 10 a.m.: To consider reports on the paperhangings question and the stores shops, and to take resolutions thereupon. Paper: "The Need for Reviving the Apprenticeship System." Mr. John H. Cantrill; discussion. 11 a.m.: Paper (subject announced later); discussion. 2.30 p.m.: Demonstration by Mr. W. J. Cloake (Past Master of the Company of Painter Stainers), who will illustrate the methods of working four different marble panels—siena, rouge, black and gold, and Irish green. This meeting will be open free to apprentices of master painters in Sheffield. Annual business meeting and election of officers, etc., for 1909-10; votes of thanks to retiring officers and committees. 7.15: Annual dinner, Royal Victoria Station Hotel; tickets, 5s. each. Thursday, September 16th: Excursion to Matlock, Haddon Hall, and Bakewell; tickets, 9s. 6d. each. Tickets for the excursion and dinner to be obtained from Mr. Sam Talford, 430, Abbeydale Road, Sheffield. Friday, September 17th: The Committec are hoping to arrange to give the visitors a view of some of the large and famous works at Sheffield.

For enduring roofing material and workmanship,

Architects, Engineers & Surveyors

are respectfully recommended to specify

ETERNIT REGISTERED TRADE MARK 1904.

Guaranteed and manufactured under Hatschek's Original Specification and to decline all substitutes. No other roofing tile is "ETERNIT." (Regd.)

WRITE FOR SAMPLES AND FOR TENDERS FOR FIXING.

Smooth on both sides. Roofs covered with "Eternit" Tiles weigh about 22 lbs. per square yard, or 66½ lbs. lighter weight per square laid than Bangor Slates. Greater mechanical and tensile strength. Non-Conducting. Non-Combustible. Impervious to sun, heat, frost and rain. Wind, dust and weather tight.

G. R. SPEAKER & Co.,
CONTRACTORS,

28,
MARK LANE,
LONDON, E.C.

GUARANTEED:
Tensile strength, 5781 lbs.
Crushing force 8,281 lbs.
Per Square Inch and always increasing with age.
Immunity from repairs.

Architects, Engineers and Surveyors are earnestly warned not to confound "Eternit" Tiles with so-called Asbestos Slates varying in quality, thickness and colour, advertised under fancy brands. "Eternit" "endures not for an age, but for all time."

Whole Page - - 10in. deep by 7in. wide.

A Booklet, giving all particulars of this number, which is being thoroughly revised and brought up-to-date, will be sent upon application.

TECHNICAL JOURNALS, Ltd., Caxton House, Westminster, S.W.

"NOTHING Comes to the Man Who Waits."

THAT'S the true version of the old proverb—as regards "promotion" at any rate. The man who is content to **wait** until promotion comes his way will take off his coat at 6 a.m. when he is 50, just as he did when he was 21—unless, indeed, he has been displaced before.

Will you be still "waiting" for promotion when you reach middle age?

You **need** not be, and it surely necessitates only a very little thought for you to determine that you **will** not be. By pursuing a course of practical, remunerative training **now**, you can ensure yourself a future of success and happiness instead of an unending repetition of "the same old grind."

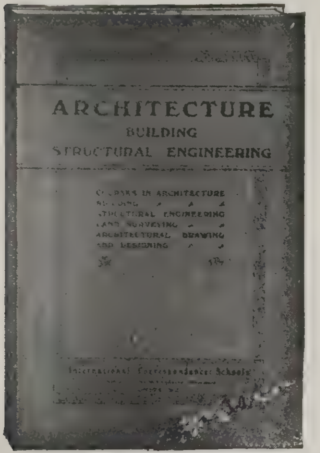
You can get this emancipating training at home, in your spare time, and on terms to suit your pocket, through the International Correspondence Schools. During the past 17 years we have enabled thousands of men and women to secure a future free from anxiety. This is typical testimony from one of our students:—

"I had a good opportunity of bettering myself, but my technical education was poor. Technical schools and evening classes I attended for four years, but found I was not getting the experience and knowledge I ought to have had. I got very disheartened. I made enquiries and asked for advice, and was told of the I.C.S. I joined the Schools, and never regret the day when I did so, as I have reaped the rewards which tend to advance me still further in the near future. Any fellow who is willing to learn and work has only to join the Schools and his success is sure. I thoroughly recommend the I.C.S. to any young fellow who wishes to become a success in life."

The reason of the sure success of the I.C.S. student is that the training we give him has **the one and only aim of qualifying him for an advancement** in his chosen line.

Isn't it well worth your while to learn what we can do to make **your** future bright? Mark the coupon, or write us about any other career in which you are interested. Don't "wait" another day.

Determine to "act" now.



Free books on subjects below.

80

Registrar, INTERNATIONAL CORRESPONDENCE SCHOOLS, Ltd., (Dept. B.), International Buildings, Kingsway, London, W.C.

I am interested in your system of Technical Training and desire to increase my earning power. Please send me, post paid, free of charge, the Book covering the subject before which I have marked **X** on the coupon, and full information showing how I can succeed in same.

Grimsby Town Hall Extension. That out of the 104 architects who applied for particulars of this competition, 45, or nearly half, returned the paper and had their deposits refunded, may be explained by the uncertainty of the Council and its intentions regarding the whole scheme. Since the meeting when it was decided to proceed with the competition and Sir Alfred Gelder was appointed assessor, considerable opposition has arisen within the Council against the whole proposal, and this has been manifested by blocking every trivial intermediate step in connection with the scheme. It need hardly be pointed out that the proper time for opposition was when the matter was first brought up. The decision of the Council to proceed with the competition, when determined by voting, should end opposition to the scheme, otherwise great injustice is done to the architects and the assessor, who may very probably find the whole of their work thrown away. The appointment of Sir Alfred Gelder, which was duly announced as settled, was not confirmed on reference to the full Council, because of opposition—not to the distinguished architect himself, but to the scheme which he was engaged to assess. This confirmation being merely a formal matter, such tactics seem unworthy of a body like the Grimsby Town Council, and we are not surprised that the Mayor should have appealed at the meeting of the Finance Committee for the Councillors to be honest with each other, or that he should say that their conduct in the matter was unseemly, and should request the Council to preserve its dignity and do the thing in a decent way.

White Lead. The information that the French Government has passed a law prohibiting the use of white lead will be of unusual interest to the Building Trade generally, and to the painters and decorators especially. The law enacts that after the expiration of five years, the use of white lead, or of paint composed of linseed oil and white lead, and of all special compounds containing white lead in any form shall be prohibited for every description of painting work. This drastic enactment is designed to remove the causes of plumbism, which has made terrible ravages among the workpeople in the manufactories and among painters and other workmen using white lead. The proposal for its total prohibition has been debated in the French Parliament for over five years, and has been carried in the teeth of very strenuous opposition by the manufacturers. We presume that, following the example of France, the prohibition of white lead in this and other countries will follow in due course. At the same time prohibition will not now result in such a revolution in painting and decorative work as it would some years ago. The great increase in the use of zinc oxide as the basis for paint has within recent years made considerable difference to the white lead business. The enormous amount of white enamel now used (which is invariably made from zinc oxide) for decorative work has not been without its influence in preparing us for a still wider use of zinc oxide paint. Though zinc oxide is dearer than white lead, it is much lighter, and weight for weight it spreads over a much larger surface, the expense finally being about the same. Moreover zinc oxide keeps a lasting white colour, resisting sea air and sulphur fumes. On the whole, therefore, if white lead has to go, an efficient, and, in some respects, superior article is to hand to take its place; and this fact makes the idea of prohibition far less disturbing than it otherwise would be.

Guide Books and Architecture. An architect who is spending his holidays in England, and in the enjoyment of what he describes as "a modest little tour in search of the picturesque in scenery in buildings," complains of the ineptitude of the cheap modern guide-books that have recently become so plentiful. The modern popular guide-book, he says, is superficially attractive, and, when it is not actually given away by an enterprising advertising corporation, may be bought for a few coppers; but, as a rule, while it is garrulous about the "attractions"—the bands, the sands, the bathing, the "walks and drives," and the "entertainments"—it conveys very little substantial information on things that really matter to the intelligent enquirer. In particular, there is little or nothing about architecture, and the occasional observations on this subject are usually idiotic, as when one is solemnly informed that a certain royal residence "is in the domestic style of architecture." It is a pity that the gratis or penny or twopenny guide should be everywhere superseding the old type of book, which, published at sixpence or a shilling, was often written by a local scholar—vicar, architect, or archæologist, who knew and loved every stone of every worthy building within his purview—and was a thing to be treasured. Our correspondent had, of course, provided himself with the indispensable and scholarly general guides issued by Murray, to whose publications in this kind architects are under considerable obligations; but he holds that the necessarily compressed information these contain should be supplemented or expanded in the purely local guides. That used to be the rule, but apparently is so no longer. Our correspondent adds that in his view the most dismal aspect of the case is the confidence with which the compilers of cheap, showy, up-to-date guide-books assume the public indifference to architectural interest. Frequently, in dealing with important modern public buildings, they omit to mention the name of the architect, thus following the bad precedent of the daily press. This is hardly fair to the public, of whose awakening interest in art and architecture we are being so persistently assured; and it is distinctly unjust to the architect, who might do better work if he got more recognition.

Westminster Abbey Museum. There is, it appears, a proposal to set aside a portion of Westminster Abbey as a kind of museum of relics and antiquities. The suggestion is giving rise to a great deal of opposition; one hardly sees why. The relics are already there, but are scattered and unclassified. The objection, therefore, can only apply to their assembly and classification, and perhaps to the probable charge for admission. This, it must be admitted, is suggestive of profanation, although, in reality, waiving the matter of charge, the question is merely that of distinguishing between profanation dispersed and profanation congested, and one would prefer to leave it to be determined by the casuists. Our own view of the matter is, that while we can have nothing to do with the purely pietistic aspect of the case, we are so far concerned in the Church's dictum of doing things "decently and in order" as to trust that whatever course may be adopted with respect to the Abbey relics may be taken with due consideration for the architectural dignity of the building. That object might possibly be best served by clearing out a large number of ugly and intrusive effigies, whether of bronze or stone, or wood or waxwork, which, for all the artistic or historical interest they possess, might without the least remorse be relegated to the nearest dust destructor. It it a pity that they were ever admitted to the Abbey. The custodians of a temple of religion should not be allowed to accumulate a miscellaneous collection of objects that invites comparisons with Madame Tussaud's and the average local museum. Such objects, besides introducing too many elements of mundane distraction, detract from the purity and grandeur of the temple as a building, interrupting its lines and falsifying its values. The proper course with both the Abbey and St. Paul's would be to take the advice of the architects in making a general clearance of the inappropriate objects that, against all the canons of good taste, have been admitted to the sanctuary, at any rate in point of architectural propriety, they by no means deserve. If it is the aim of the Abbey authorities to remove such objects to the obscurity of some crypt or lumber-room, architects will feel no inclination to rise up in protest. Forty or fifty years ago, when a somewhat similar proposal was carried into effect, Thomas Hood wrote a long and scathingly satirical poem against it; but, if memory serves us, the chief ground of his objection was the charge for admission. Still, if people can be got to pay for seeing the monstrosities that at present disfigure and profane the public parts of the Abbey, the only objection that we can see is that the system perpetuates the existence of a good deal of rubbish that might well be destroyed.

The City of the Future. Dr. Houriet, of Paris, has just been giving to the world his conception of the model city of the future. The first problem is that of site. It must be dry and easily drained. Then comes the task of planning, and here the first question is that of orientation. It is necessary to study the direction and character of the winds, and to so lay out the streets that a free circulation is offered to those winds which are laden with ozone, and free from carbonic acid gas and other contaminations. The main streets would all be laid out parallel to each other, with intersecting cross streets. Houses would be erected on either side of the main streets, each house "pointing both ways," that is to say, no back-to-back houses would be tolerated, nor would gardens be allowed. Moreover, the houses would have only one row of rooms, facing the main street, with a corridor at the back. Thus through ventilation would be assured. As the aim would be to flood house fronts and rooms with air and sunlight, no balconies would be permitted on the room side of the houses, but they could be placed at the back, leading out of the corridors. All roofs would be flat for the sake of safety, and to do away with attics. These roofs could be arranged as playgrounds or gardens. The main avenues would be wide, the minimum width being calculated according to aspect, so as to ensure that the whole house front, from street level to roof, should be at least once every twenty-four hours exposed to the sunrays. The footpaths would also be wide, and would be divided from the carriage ways by garden borders. These would not be tree planted, because trees obstruct sunlight and induce dampness, but shrubs would be arranged in picturesque groups, and in the chief avenues these borders would be dainty flower and shrub gardens, the shrubs interspersed with architectural pedestals supporting vases and sculptures. The side streets would be comparatively narrow, their width equal to the height of the houses; but as they would be cut up into short lengths, as they would only have the same length as the depth of a house, they would always be sufficiently ventilated. Rather more latitude would be allowed for public buildings. These might occupy the sites of two or more blocks, but would always be so arranged as to be isolated, fronting on two main avenues, and on two side streets, which in these cases would be wider than usual. Many of these buildings would be placed opposite the public gardens, which would be of about an acre in extent, and placed at frequent intervals, having due regard to picturesque effect, but so arranged that no house should be further away than a quarter of an hour's stroll from one of them. Larger public parks could be arranged, in such a way as to avoid dampness, but such large parks should not be used as substitutes for the playground gardens. It will be seen that Dr. Heuriot's model city would demand considerable space, and a more strict attention to meteorology. Unquestionably, such a town-planning policy as here set forth would present most interesting problems both to architects and builders.

Whitgift Hospital. The demolition of the Whitgift Hospital at Croydon is still advocated in the "Croydon Chronicle," in spite of the chorus of protest that has greeted the proposal. The current issue of that journal contains a very temperately and courteously-written leader, in which reference is made to the observations on the subject that appeared in our columns a fortnight ago. Our contemporary tacitly admits the truth of our contention that the Whitgift Hospital is a veritable work of art, and even goes so far as to concede that "there is much within the interior that is unique and even beautiful"; but he pleads that the building is out of harmony with its surroundings, and that it obstructs necessary improvements. Our contemporary fears that we are considering the question without due regard for the sanitary standpoint. But surely the condition of the Whitgift Hospital would not present an insoluble problem to the sanitary engineer. The Whitgift Hospital is not to be condemned upon such a charge as this. The contention that the site is required for street improvements is not without force, but we do not think that the argument is of sufficient weight to justify the destruction of this Elizabethan gem, which we are by no means alone in regarding as the most beautiful building in Croydon. Our contemporary's concluding appeal for a pure "unadulterated style—a real twentieth century design" is curious when read in the light of his eulogium on "the fine stately buildings erected close by the Whitgift Hospital." Nevertheless, he thinks that the architect of today is too greatly addicted to the copying of old models. Of course, any competent architect could reassure him on this point. Style is no mushroom growth. It is evolved, more or less slowly and tentatively, by the very process that he condemns. In this sense Brunelleschi, Inigo Jones, Wren—in fact, all the great architects—are what our contemporary would probably regard as "copyists." *Ex nihilo nihil fit.*

A new United Free Church at Whiting Bay is to be built of brick rough cast, with the sandstone facings from Barskimming. In the nave there will be seating for about 300, and in the transepts for about 150. The building will have a spire. A suitable manse will also be erected. The architects for both church and manse are Messrs. J. W. and J. Laird, 163, Hope Street, Glasgow.

London Suburbs.

III.—Dulwich and Norwood.

Dulwich and its neighbour, Norwood, are modern if not new, and each has a distinctive character. Dulwich has grown from a pretty hamlet into a large suburb of villas of many sizes and styles, placed in a valley, the favourite site for most old builders, who sought for shelter above all things. It is nevertheless a hundred feet above the level of the Thames. Its attractiveness lies very much in its green leafiness, and this is due partly to the preservation in the heart of the neighbourhood of the beautiful grounds of an old foundation—Dulwich College. Grand and stately trees surround the "College of God's Gift," founded by Edward Alleyne, actor, and "keeper of the King's bears" to James I. Seventy-two acres of the estate were given by the College estate to the London County Council, for a public park, a gift estimated at a thousand pounds an acre. The College designed by the younger Barry, rises in three great groups or blocks, mainly in red brick, connected by open cloisters; the detail is taken from northern Italy; and the whole group is well seen from the railway. Older buildings remain, and in one is the small but interesting picture gallery. The collection was originally formed for the last King of Poland. The gallery is mentioned sympathetically by Kingsley in his "Alton Locke."

Dulwich is as good an example as could be desired of a village, which grew into a suburb in the Victorian time, when the villa flourished and suburban flats were as yet unknown, handsome houses in good gardens, many trees, and pleasant roads of smaller residences. Building operations have of course spoilt not a few pretty "walks," but many remain, and the suburb is a pleasant one.

It is in strong contrast with its ambitious neighbour, Norwood. For whilst Dulwich represents the old idea, so resolutely clung to by our forefathers, of choosing a valley for their residence, Norwood exhibits the modern idea, insisted upon by sanitary reformers, of building on a hill. It stands upon the highest ground available for many miles, and commands an unrivalled view. Its origin is interesting; it was a well-known health resort long ago, owing to the proximity of the Beulah Spa, to which many people resorted to "take the waters." To this Norwood can claim possession of several good hotels, and the "villa residences" in many cases rise to mansions, whilst the gardens are large and luxuriant. It is remarkable that the steepness of the hill is not objected to by anybody, and the train service to London is frequent. But the growth of this great suburb was largely due to the creation of the Crystal Palace.

This was, perhaps, the greatest work of the Victorian era. Ruskin, indeed, declared that after all it was only "a conservatory," but it is the finest conservatory in the world, with a length of 1,608ft., immense width, and a height of 175ft., flooded with light in every part, it is a remarkable and interesting structure. The grounds with their vast terraces, the superb fountains, the remarkable newspaper room, the concerts, the lectures, and exhibitions made up a total which was unique in its day, and at one time it seemed as if "the Palace" would swallow up every form of popular entertainment. Its purpose however, was education rather than amusement. Time, and the opening of new entertainments and exhibitions in London have led to a decline in its popularity. One remarkable attempt at the education of the public on a subject of which they know far too little, was made in the architectura courts. These, commencing with ancien Egypt, led the visitor through Greece and Rome, to the Romanesque and early Gothic But the gem of the series was, or rather, is for it still exists, the beautiful reproduction on a reduced scale, of the Court of Lions, in the Alhambra of Granada, with its pendentives in violet-blue, with thin lines of gold

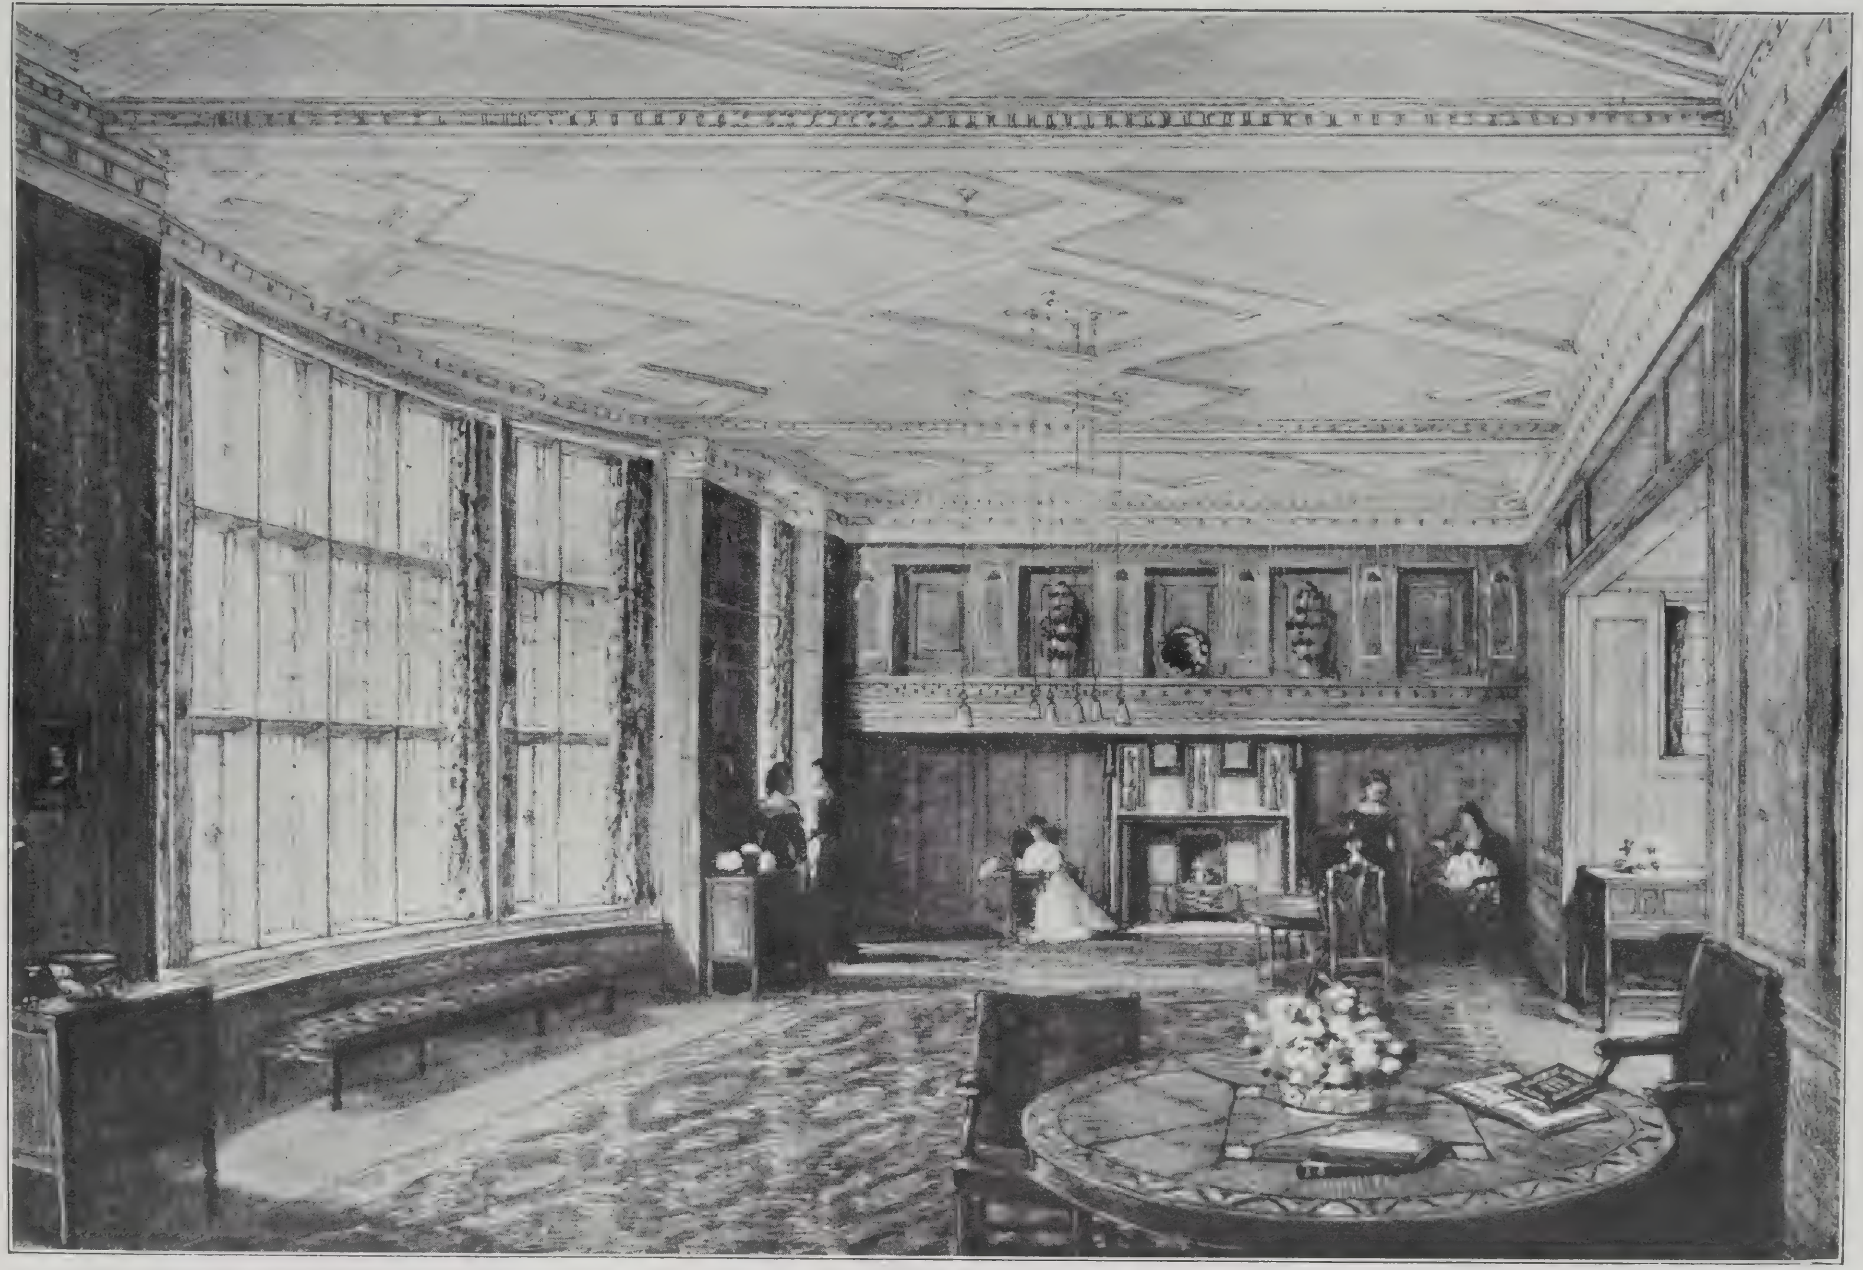
CASTLE AND WARREN, ARCHITECTS.



ADDITIONS TO BRANDON, SHEFFIELD. EDGAR WOOD, A.R.I.B.A., ARCHITECT.

and vermilion. It was the work of the late Owen Jones.

A little southward of the Palace the high ridge ceases and falls into the woodland of Surrey—pre-eminently the suburban county of the future.

DESIGN FOR A SECONDARY SCHOOL.

The secondary school of which the design is shown on p. 125 is for the accommodation of 200 boys and girls. It is in the Georgian style, Luton purple bricks being used, picked out with Fareham red with a tile roof.

The interior treatment has been kept as simple as possible, the lavatories, cloak rooms, and entrance halls having glazed brick walling and floors of red quarry tiling, while the assembly hall and classrooms have deal panelling to a height of 3ft., with plaster above and floors of oak blocks. The headmaster's and mistress's rooms overlook the main entrances, and at the same time are within easy reach of the assembly hall and classrooms.

The science and art rooms have been placed on the first floor, and are to be used jointly. For this reason it was considered better to place the masters' and mistresses' common rooms and some of the classrooms on the first floor. The architect is Mr. F. D. Sowerby, Ingram House, Stockwell, S.W.

HOUSE AT FARNHAM ROYAL, BUCKS.

This house is built at Farnham Royal, near Slough, Bucks. All the best rooms have been planned to face the front, as there is a splendid view over the valley to Windsor Castle and district. The general walling is of rough stocks covered with cement rough-cast of a white tint, the plinth being of red and purple bricks. The filling between the half timbering is of cement plaster with a tinge of ochre. The porch is of Bath stone, with the joints slightly recessed with dark blue pointing, and roof covered with hand-made sand-faced tiles. The pitch pine joists and beams of hall and dining room are exposed, and stained a dark tint. The windows are lead lights with steel cores to the cames.

The architects are Messrs. Moscrop-Young and Glanfield, of 12, Buckingham Street, Strand, W.C., and the builder is Mr. H. D. Bowyer, of Slough.

Our Plate.

House at Byfleet for Karl Bruckhaus, Esq.

This house is to be erected at Woodham Lane, West Byfleet, in brick and smooth plaster, with old tiles for the roof slopes. The plan is arranged so as to obtain the best views from the principal rooms. The details will be of a simple character throughout, and 2in. Dutch bricks used where the brickwork is revealed to window-sills, etc. The window frames generally are to be in Oregon pine, but the dining room is to be panelled out of Austrian oak, and broad old oak beams revealed in the ceiling. The casements are to be in iron of a broad and flat section. A special feature is to be made in the treatment of the gardens. Messrs. Castle and Warren, of London, are the architects.

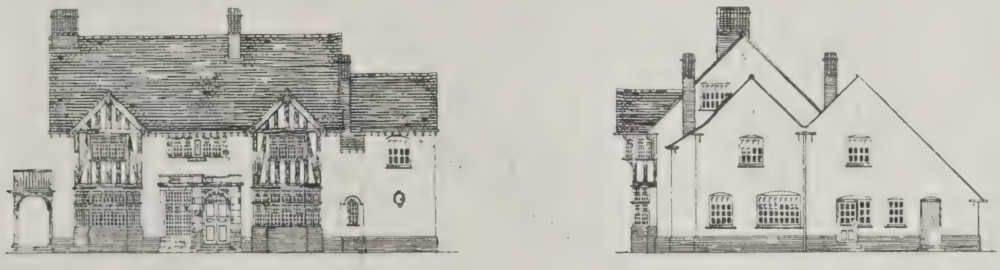
Additions to Brandon, Sheffield.

This interior is finished in fumed oak panelling with oak floors; the chimney pieces in marble of Verde Antico, Siena, and Arni vein. The masonry was by Mastin and Sons, Sheffield, and the woodwork, including oak, by John Booth, Sheffield. Mr. Edgar Wood, A.R.I.B.A., of Manchester, is the architect.

Mr. E. Douglas Hoyland, architect and surveyor, has removed from 2, Walbrook, E.C., to 10, John Street, Adelphi, W.C. Telephone, Gerrard 4783.

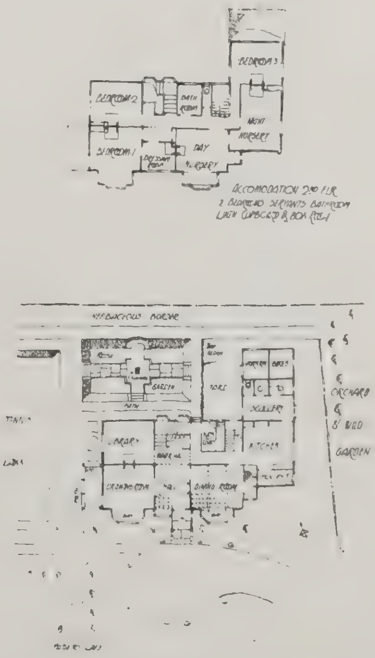
* * *

Advantage is being taken of the civic vacation to increase the provisions against fire at the Mansion House. The work is being executed for the Corporation on plans and suggestions made by Mr. Sydney Perks, F.R.I.B.A., City Surveyor. The general scheme is the separation of the Egyptian Hall from the domestic offices and state apartments by means of steel doors. Special attention is being given to the Egyptian Hall, as it is erected immediately over the kitchens. Iron and steel doors are also being erected in the state drawing rooms and the saloon, and an iron and glass screen will be placed at the east end of the Egyptian Hall. Iron gangways are being placed on the roof to facilitate the escape of the domestic staff, and fire alarms and appliances are being overhauled and hand extinguishers provided throughout the building. The cost of these works will be over £1,000. So far no fire has ever occurred in the Mansion House.



HOUSE AT FARNHAM·ROYAL·BUCKS·FOR·KYRLE·C·HANKINSON·ESQ·

MOSCROP-YOUNG & GLANFIELD Architects



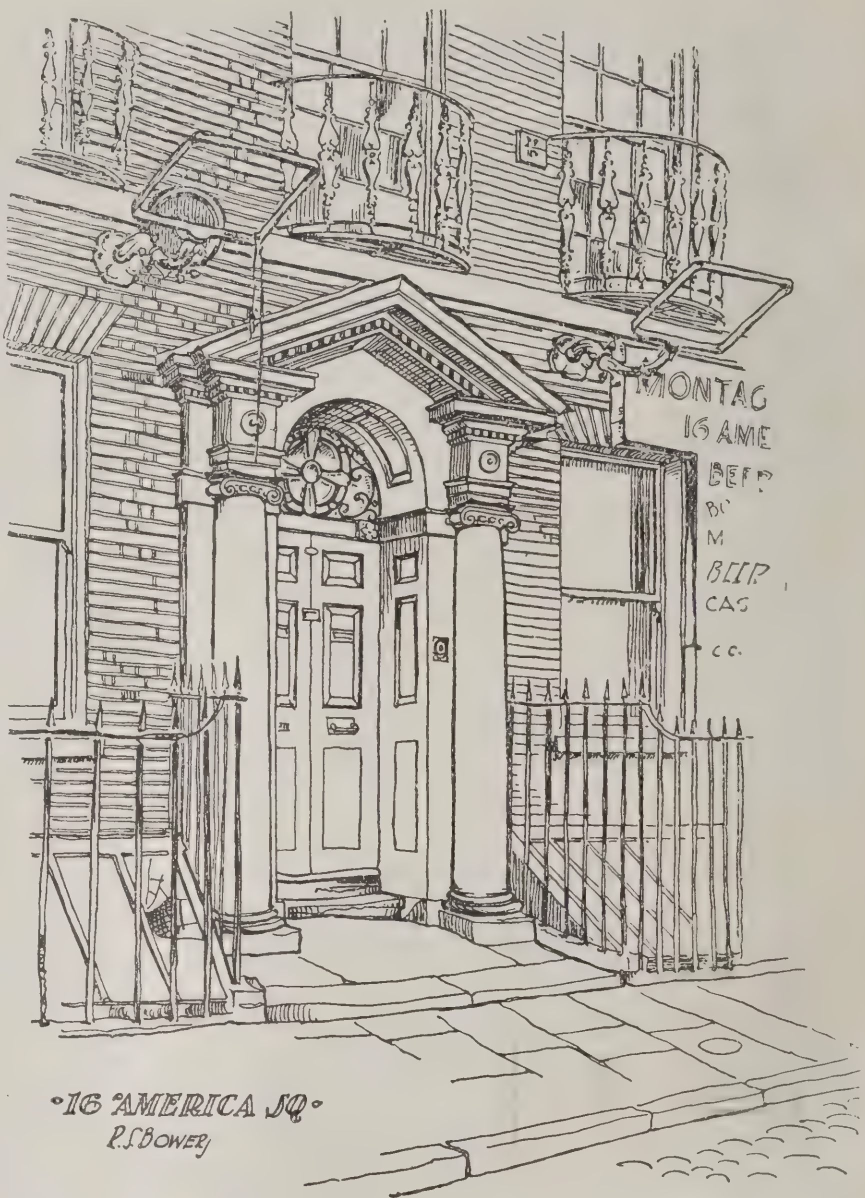
In this house, all the best rooms have been planned to face the front, as there is a splendid view over the valley to Windsor Castle. The general walling is of rough stocks, covered with cement rough-cast of a white tint, the plinth being of red and purple bricks. The porch is of Bath stone, with the joints slightly recessed with dark blue pointing, and the roof is covered with hand-made sand faced tiles.

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Aug. 30	FOREST HALL, Elementary school for 250 scholars. County of Northumberland Education Committee invite designs from architects practising in the County and in the City and County of Newcastle-on-Tyne. Particulars, conditions, and plan of site from C. Williams, Secretary to the Education Committee, The Moothall, Newcastle-on-Tyne.
Aug. 31	HUDDERSFIELD NEW CHURCH. Plans are invited for a church to seat 400, to cost about £2,000, not to exceed £2,500, with all fittings, furnishings, lighting and heating apparatus. Plans to be forwarded to the Rev. D. Macrae Tod, B.D., St. James' Manse, Huddersfield, by Aug. 31.
Sept. 1	BRANCH LIBRARY, NEW CROSS, for Deptford Borough Council. Limited to Architects practising in the City or the County of London. Assessor: J. S. Gibson, Vice Pres. R.I.B.A. Premiums, £52 10s., £26 5s., and £10 10s., for three selected designs, and will be awarded in accordance with the conditions contained in the instructions to competitors. Site plan and copy of instruction from Vivian Orchard, Town Hall, New Cross Road, S.E. Deposit £1 1s., refunded on receipt of *bona fide* design or if instructions are returned within 21 days.
Sept. 1.	NEWBURN. Council Chamber Offices and Caretaker's house. The Newburn U.D. Council invite designs for these buildings to be erected in Newburn Lane, Newburn. Open only to Architects practising in Newcastle-upon-Tyne and in the County of Northumberland. The author of the design considered the best will, subject to the general instructions and conditions of the competition, be employed to carry out the work. A premium of £10 will be awarded to the author of the design considered second in the order of merit. The Council has appointed Mr. Richard John Leeson, of the firm of Oliver, Leeson, and Wood, of Milburn House, Newcastle-upon-Tyne, architects, as assessor. A plan of the site and a copy of the general instructions and conditions of the competition may be obtained from George Wilkinson, Clerk to the Council, 1, Mosley Street, Newcastle-upon-Tyne, on payment of a deposit of One Guinea, which will be returned on receipt of a *bona fide* design, or it the plan of the site and copy of the general instructions and conditions are returned within 14 days with a notification of non-intention to compete. The designs are to be delivered at the Clerk's Office, No. 1, Mosley Street, Newcastle-upon-Tyne.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.
Oct. 11.	HULL TRAINING COLLEGE for Teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd, and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.



DOORWAY AT 16, AMERICA SQUARE, E.C. (NOW DESTROYED). DRAWN BY P. S. BOWERS.

Grimsby Town Hall Extension.

At the last meeting of the Finance Committee of the Grimsby Corporation it was decided to send the designs received in this competition to Sir Alfred Gelder, F.R.I.B.A., for adjudication. Since the competition was originally instituted a certain section of the Council has opposed every resolution for going forward with the scheme, and at the meeting in question the decision to send the plans to an assessor was only passed by 12 votes to 9. It further appears that the appointment of an assessor was not confirmed by the full Council. Though the Council has now decided to proceed with the adjudication of the plans, it does not seem certain that the extension will be started without further obstruction. The Borough Surveyor reported that 104 architects had applied for particulars; 45 had returned the papers and had their deposit refunded, leaving 59 deposits still in the hands of the corporation, and that 50 architects had sent in 51 designs, one of them sending in an alternative.

The Cornwall County Offices.

The Cornwall County Council has at last decided to proceed with the erection of its new offices at Truro, but the cost is to be limited to between £10,000 and £12,000, eliminating from the first design the Council Chamber, dining room, lavatories, retiring rooms, and modifying the plans as regards the caretaker's quarters and committee room accommodation. A special committee has been empowered to invite alternative tenders on a complete scheme. A motion to erect the offices at St. Austell was defeated by a considerable majority.

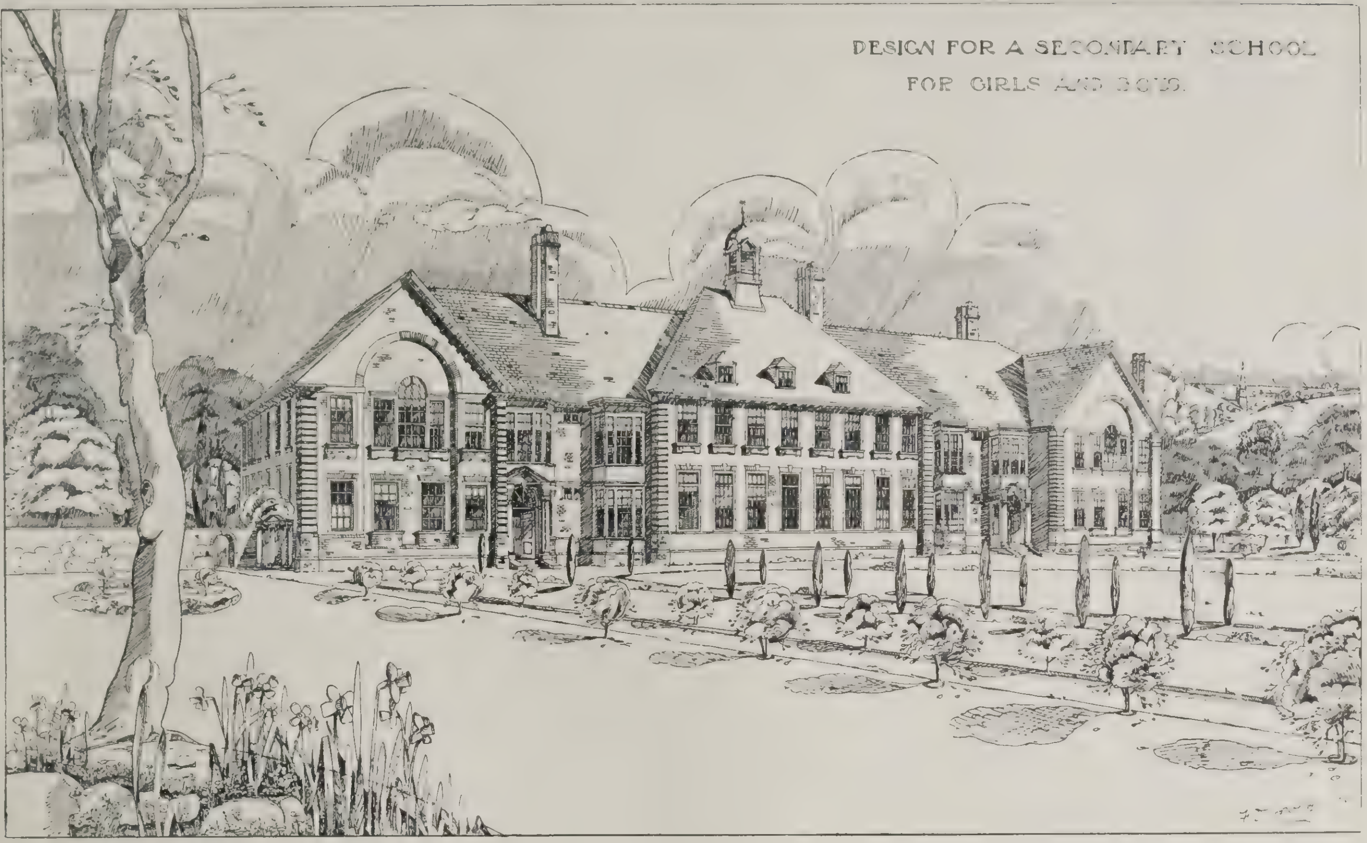
No. 16, AMERICA SQUARE MINORIES.

This is a sketch of the doorway to No. 16, America Square, just off the Minories, made prior to its demolition last year.

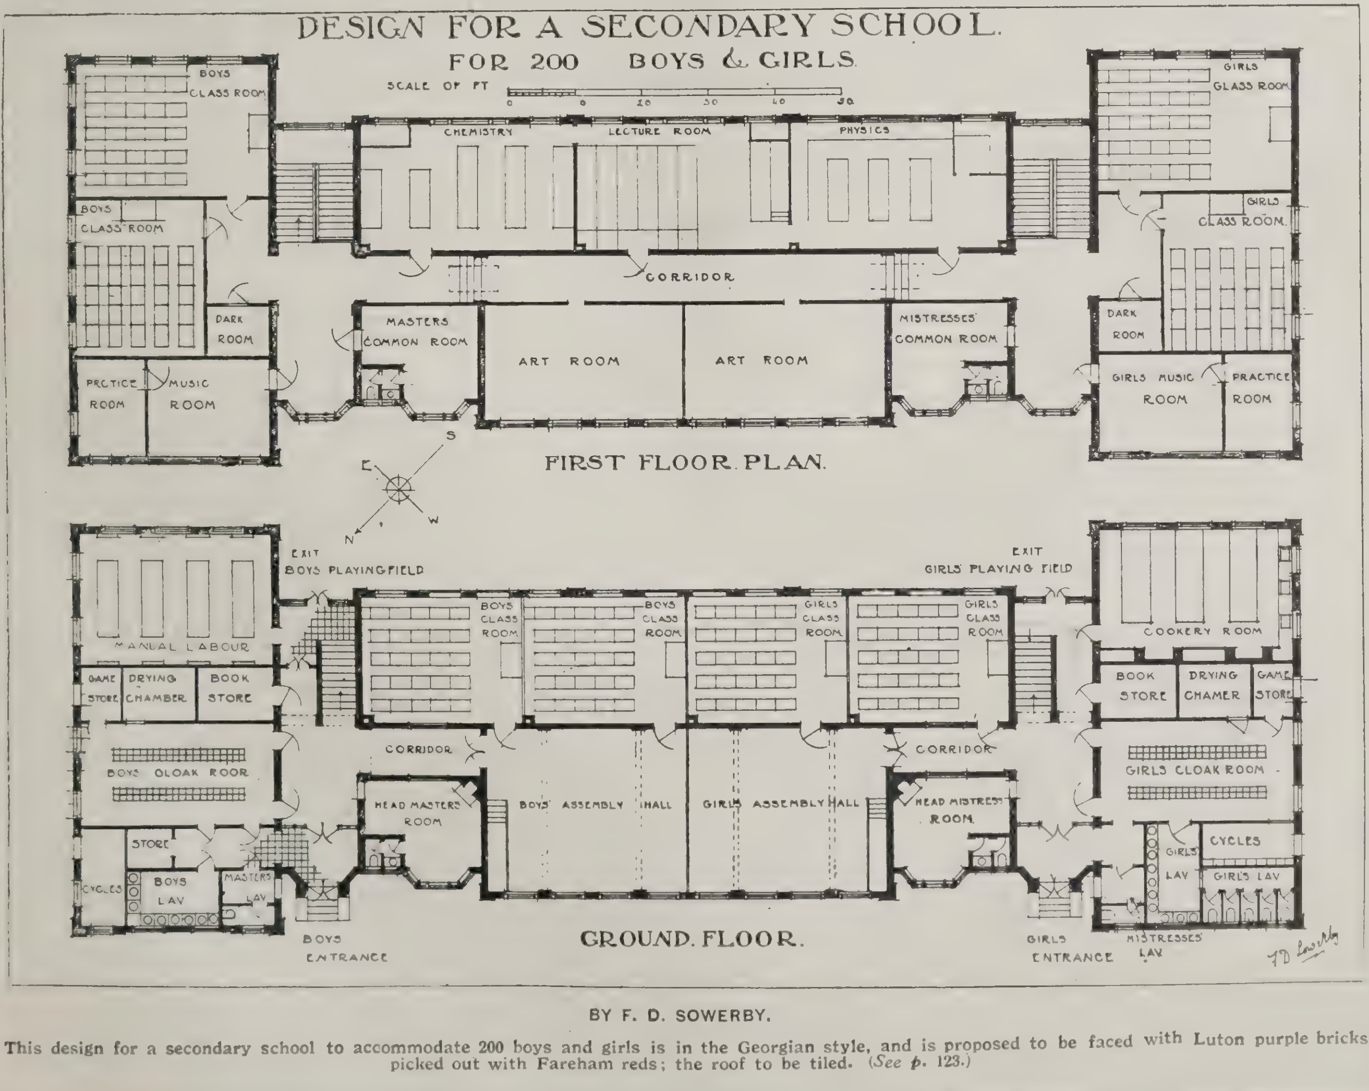
It may be recalled that on the site of this fine old City house a large portion of the wall built by the Romans around London was discovered, about ten feet below the pavement, as perfect and massive as when first constructed. In fact, the eighteenth century builder of America Square who used it as the footings for his real wall, but omitted to provide foundations elsewhere, had the fearful joy of watching the house settling in front only, and consequently tilting bodily over the street, a position it must have been in for many years.

One of the upper floors of this house had a window built across on the inside face, and inserted, as is sometimes found, simply to keep the regular spacing of openings on the elevation.

Malvern has a priceless possession in its old Priory Church, and Mr. F. Bligh Bond, F.R.I.B.A., has been appointed its consulting architect at the instance of the recently appointed Vicar, the Rev. Anthony Deane, and with the concurrence of the wardens.



DESIGN FOR A SECONDARY SCHOOL
FOR GIRLS AND BOYS.



BY F. D. SOWERBY.

This design for a secondary school to accommodate 200 boys and girls is in the Georgian style, and is proposed to be faced with Luton purple bricks, picked out with Fareham reds; the roof to be tiled. (*See p.* 123.)

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himself of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable: and it must be understood that both question and reply will, as a rule, be published in these columns

Stability of Vaulting.

BOLTON.—C. V. H. writes: "How can you calculate for the stability of the vaulting shown on the enclosed drawing?"

The vaulting is shown in section Fig. 1 and plan Fig. 2, but as querist does not give the weight of the stone or section of the ribs only an approximate answer can be given. Taking first the diagonal rib, with a section equal or equivalent to a rectangular section 8ins. by 5ins., as in Fig. 3, the loading will be as shown in the usual manner by means of Fig. 4, the curve of thrust may be drawn on Fig. 3. The maximum stress will be across space 3, then

$$\frac{W}{A} \pm \frac{M}{Z} = \frac{650}{40} \pm \frac{650 \times 1{\cdot}8}{\frac{1}{6}(5 \times 8^2)} = 16 \pm 22 = 38 \text{ lbs.}$$

per sq. in., or 2.45 tons per sq. ft. compression, and 8lbs. per sq. in., or 0.5 ton per sq. ft. tension. The short ribs, with a section equal or equivalent to a rectangular section 8ins. by 4ins., will be loaded as in Fig. 5, and by means of Fig. 6 the curve of thrust may be drawn on Fig. 5. The maximum stress in this case will be

$$\frac{W}{A} \pm \frac{M}{Z} = \frac{360}{32} \pm \frac{360 \times 2\frac{1}{3}}{\frac{1}{6}(4 \times 8^2)} = 11 \pm 19.7 = 30.7 \text{lbs.}$$

per sq. in., or 2 tons per sq. ft. compression, and 8.7lbs., or 0.56 ton per sq. ft, tension, which appears to be safe. It is usual in groining for the lower portions of the ribs to be formed out of bed stones, and those immediately above may tail more or less into the concrete. The curve of thrust may be worked out for the whole rib down to the bottom of concrete filling on the came principles.

HENRY ADAMS.

Engineering Examinations.

BRADFORD.—YORKSHIRE writes: "(1) What books do you recommend for preparation for the Assoc.M.Inst.C.E. examination (all sections). (2) What steps should student take on leaving college (and obtaining diploma) to become an engineering contractor?"

(1) Full information as to the books required (or recommended) for passing the examinations of the Institution of Civil Engineers will, we understand, be sent to an applicant intending to enter, if he writes to the Secretary at Great George-street, Westminster. Copies of papers recently set may be obtained from Messrs. W. Clowes and Sons, 23, Cockspur-street, Charing Cross, S.W., and these would give the best possible idea of the scope of each subject. When writing to the secretary for information as to books our correspondent should, if possible, state in which section he is chiefly interested. (2) The question as to the steps which should be taken after obtaining the diploma is one which can only be answered in a very "general" manner—so much depends upon the age, available capital, amount of influence obtainable and general circumstances of the applicant. Having made up his mind as to the nature and class of business in which he wishes to engage, he should correspond with firms who are eminent in that class with a view to obtaining a position in their works for a time: in such professions it is invariably necessary to obtain such practical experience and the question of premium payable or salary to be obtained would depend upon the influence of the applicant and the "standing" of the firm applied to. Finally, we may advise "Yorkshire" to obtain a book published by Messrs. Cassell and Co., La Belle Sauvage, London, E.C., entitled, "Choosing a Career," as it contains much useful information.

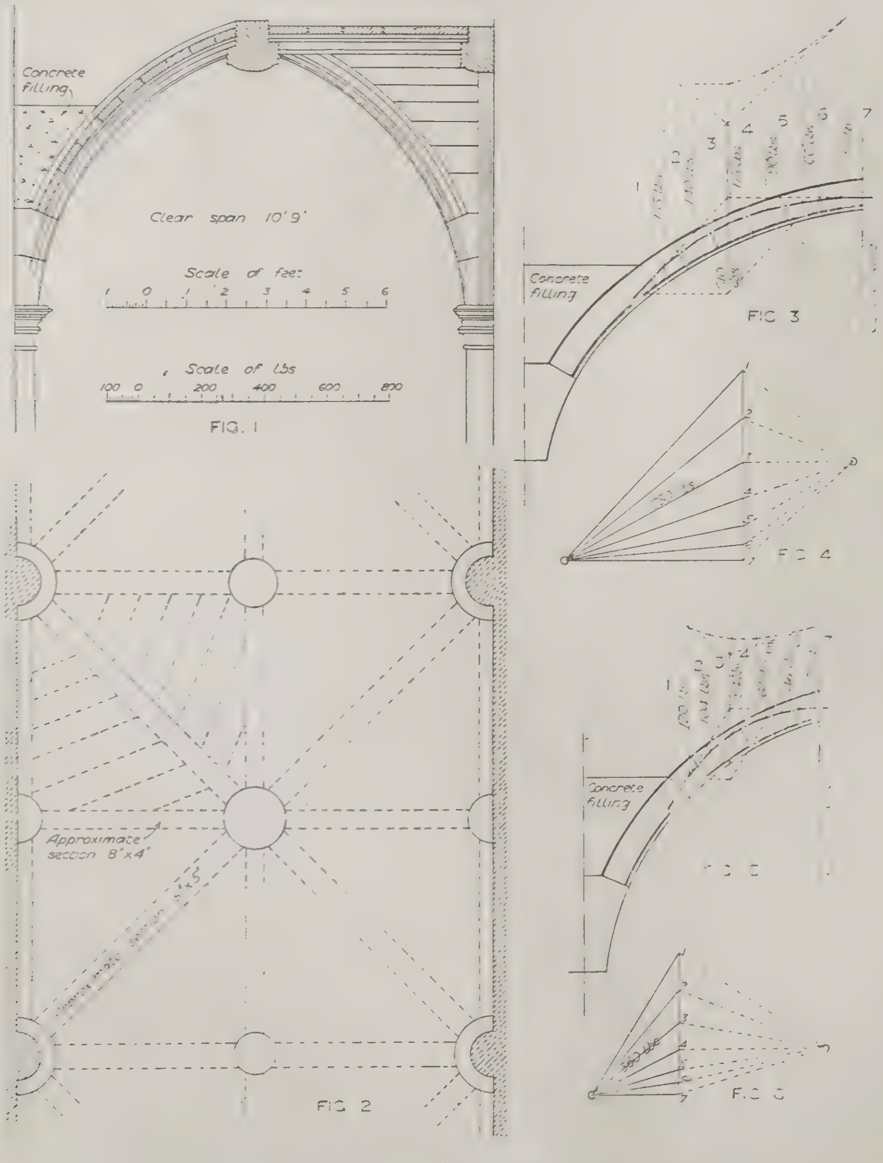
B. & B.

Steel Calculation.

EDINBURGH.—CONCRETE writes: On page 66, Specification No. 8, you will find the following:—"Let us next consider the insertion of 4in. by 1-16in. W.I. plates, with ¼in. cross rods, etc., etc. This gives us $5(4-\frac{1}{4}) \times \frac{1}{16} = \frac{75}{64}$ sq. ins. and $\frac{75}{64}$ sq. ins. × 5 tons (2240) × $3\frac{2}{3}$ ins. = 43,125 in lbs. How does this become 43,125 in. lbs.?

Why does he use 5 tons, which is the extreme fibre stress? In the next case he takes a mean the same as he also takes a mean for the concrete. I suppose the 3 2-3in. is arrived at as follows:—Depth of centre of stress in bar $= \frac{2}{3} \times 4$ ins. $= \frac{8}{3} = 2\frac{2}{3}$. Add 1in. for depth from N.A. to top of flat bar—$3\frac{2}{3}$. An explanation would be esteemed.

In the succeeding issues of "Specifications," the article referred to has been omitted. There is an obvious error to which our correspondent calls attention in the first paragraph, as regards the five tons being the extreme fibre stress. We may mention that the steel cube safely stressed to 7½ tons as the extreme fibrous stress. We see no reason in going into this at all elaborately now, as there has been considerable advance in connection with reinforced concrete during the last few years, and it is more useful to study the later theory of reinforced concrete. If our correspondent is particularly interested in the article he refers to, which is now out of date, we would advise him to communicate with the author.



STABILITY OF VAULTING. *(See Answer to "Bolton, C.V.H.")*

Proposed New Works.

BEXHILL.—The colonnade and bandstand shortly to be erected on the new Central Parade will provide accommodation for 500 people. The architect for the whole scheme is Mr. J. B. Wall, of this town.

CHIPPING SODBURY.—An inquiry has been made into the proposal to build a higher elementary school here.

DARNLEY.—It has been recommended that the plans of the proposed smallpox hospital be approved. The Local Government Board have agreed to the Joint Hospital Committee erecting the new hospital on a vacant site within the grounds of the present hospital, and its cost is estimated at £5,639.

DUDLEY.—It is estimated that the provision of a chancel and a lady chapel at the parish church will involve about £5,000. It is also contemplated that the foundation stone will be laid in October next.

DUNDEE.—The suggested alterations to be made to the Sheriff Court Buildings have been entrusted to Mr. J. Anderson, who is now engaged upon the preparation of a report.

FISHPONDS.—The original plans, prepared by Messrs. Lingham Barker, of Bristol and London, for the new church of St. John's, have been discarded on the ground of expense. The first part of the church to be proceeded with will, it is estimated, accommodate 500 persons, and cost £3,088, and the second section will provide for 200, and cost £1,892.

HUDDERSFIELD.—The Borough Engineer having reported that the present post office building could be very successfully adapted for the purposes of a County Court, Labour Bureau, and other Government purposes, it has been decided to erect a new post office on the south side of Northumberland Street, and to convert the present post office in the way suggested.

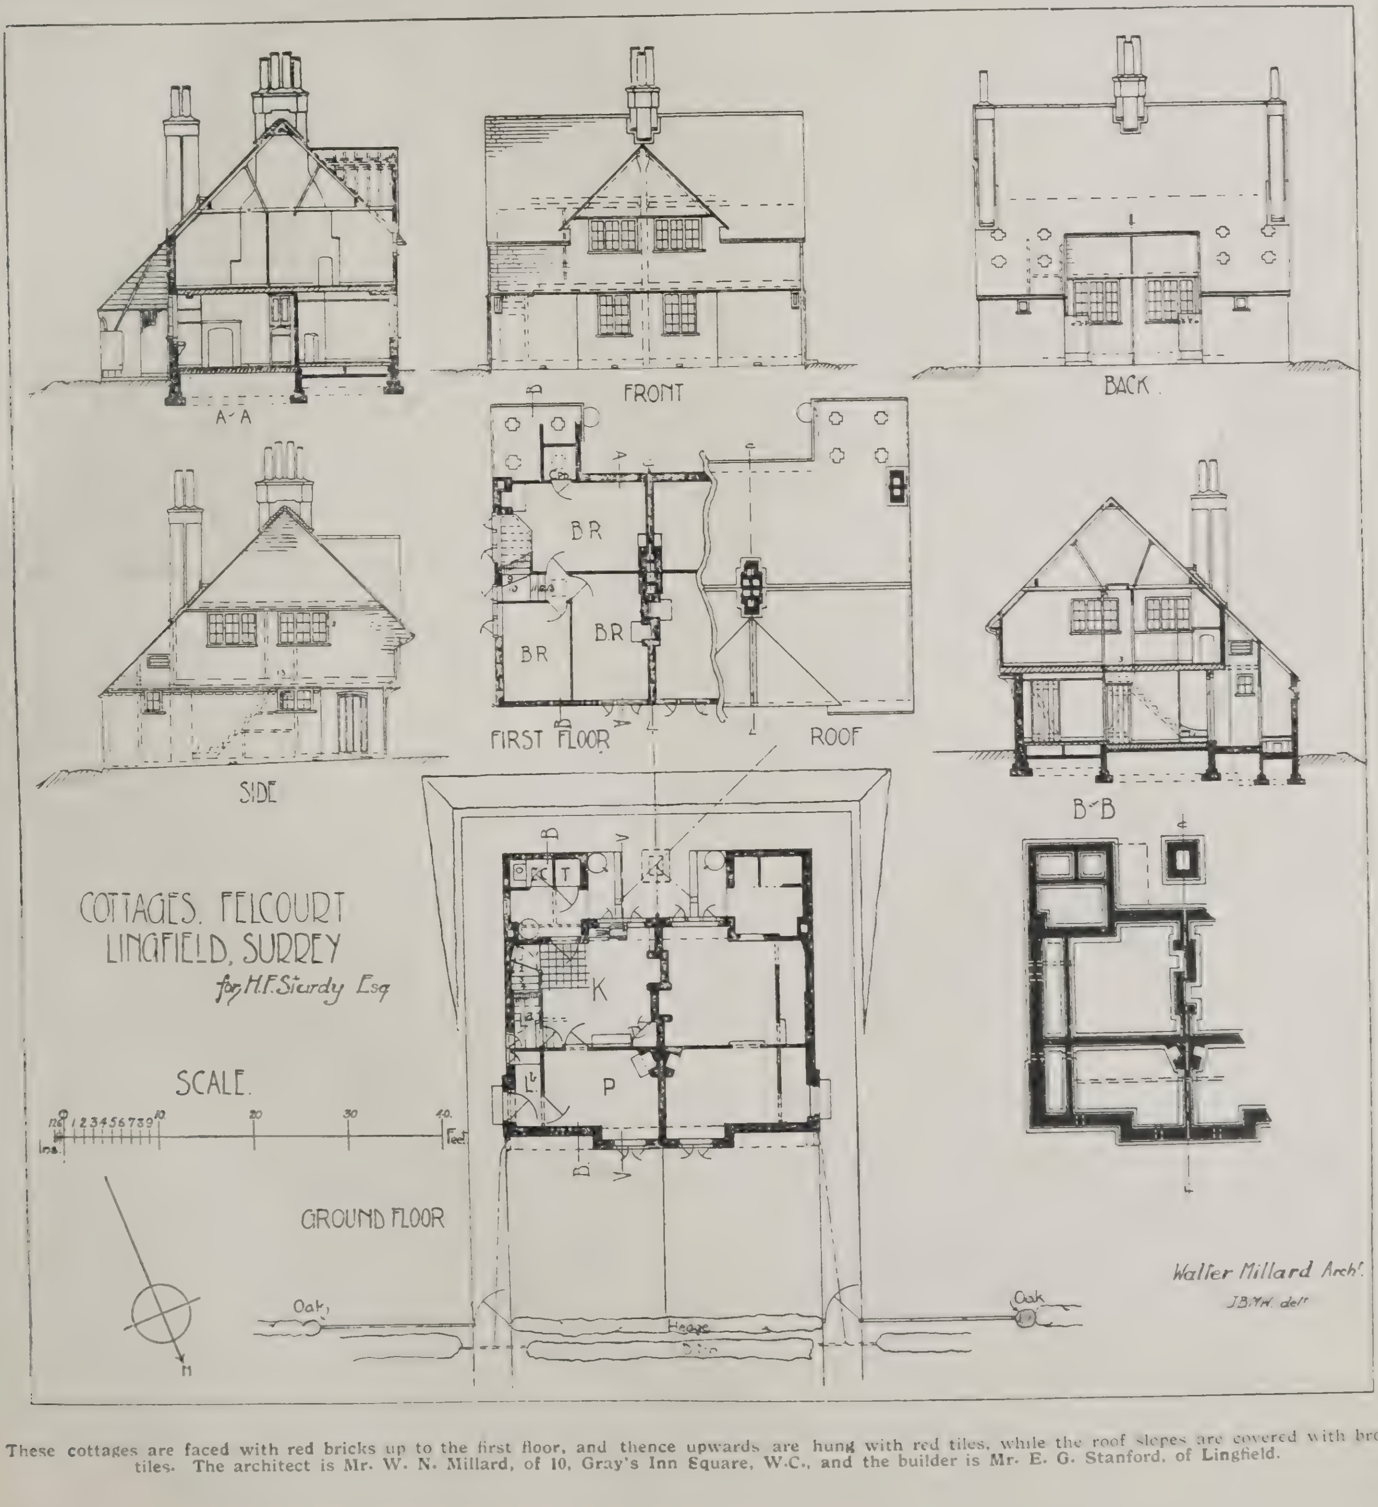
ILKESTON.—At a meeting of the Town Council it was decided that the Duke of Rutland be approached with a view to the provision of a site for the proposed new baths. The Mayor, with commendable discretion, submitted that the present moment was distinctly inopportune for any such action, if the Council's object was to obtain a site free of cost; but upon the explanation being made that the Council were not desirous of begging a site, the above decision was arrived at.

KIRKCALDY.—The Dean of Guild Court have passed plans for alterations on the shop at 18, Bridge Street. Messrs. R. Stocks and Company have been granted warrant to make extensions on their factory in Link Street, and plans for internal alterations at the King's Theatre have been passed. Messrs. M. Nairn and Company have been given permission to make alterations on their North Factory in Den Road, Kirkcaldy.

LINCOLN.—The sum of £2,000 presented to the Bishop of Lincoln on his seventy-ninth birthday for church extension in Grimsby, is to be given to the building fund of the new church of St. Luke, which will serve a poor parish of 10,000 souls. Sir Charles Nicholson's design for the church is conceived in the style of the fifteenth century. For the completion of the building as a thank-offering for Bishop King's episcopate, a sum of £4,000 will be needed.

LONDON (HARLESDEN).—Mr. Andrew Carnegie has consented to bear the cost of the enlargement of the Public Library. A lecture hall will be included in the additions.

LONDON.—Mr. Joe Elvin, the popular comedian, has propounded a scheme for the erection of a home for variety performers who are no longer able to support themselves. The proposed institution, which will include an orphanage, is estimated to cost £10,000.



These cottages are faced with red bricks up to the first floor, and thence upwards are hung with red tiles, while the roof slopes are covered with brown tiles. The architect is Mr. W. N. Millard, of 10, Gray's Inn Square, W.C., and the builder is Mr. E. G. Stanford, of Lingfield.

LONDON.—One by one London's heritages of the past in the form of old buildings are rapidly passing away. The latest disappearance to be recorded is that of the old office of the Ecclesiastical Commission, which moved a year or two ago to new palatial premises in Millbank. This is now in the hands of the housebreakers; and before long the whole of Whitehall Place will be entirely modern.

LONDON.—The Council have agreed to recommendations of the Building Act Committee consenting to the erection of an oriel window at 6 and 8, Ludgate Hill, on the application of Mr. R. Plumbe, on behalf of the chairman and directors of the Temperance Permanent Building Society; to the rebuilding of Mark Lane Station, on the application of Mr. G. Sherrin, on behalf of the Metropolitan and District Railway Companies; to the erection of a building on the site of 2 and 3, Furnival Street, on the application of Mr. C. H. Townsend, on behalf of the Food Reform Co., Ltd.; and to the uniting of 1 and 12 with No. 11, Paternoster Buildings, Paternoster Square, on the application of Mr. A. R. Conder, on behalf of Messrs. Morgan and Scott.

MANCHESTER.—The erection of a new reference library is contemplated here; but, owing to some difficulty in regard to the site, the whole matter is in abeyance for the present.

NEWCASTLE. — Negotiations with the Corporation for the construction of a stadium in the Ouseburn are now proceeding. It is hoped that the structure will be ready by next June.

SEAHAM.—The proposal to build a new public elementary school for about 480 children at Seaham Harbour, and another such school for about 450 childen at New Seaham has resulted in an inquiry into the effect that the erection of these buildings will have upon the rates.

STOCKPORT.—The directors of the Stockport Mechanics' Institute have decided to accept the offer of the Corporation to pay £2,150 for the building and site, and to take over the staff, in order to provide a site for the new library which Mr. Carnegie has offered to build at a cost of £10,000.

WALLSEND.—The surveyor has received instructions to prepare plans showing the amount of land required for the provision of a swimming bath 80 feet by 30 feet, 12 slipper baths, etc.

WELTON.—It is estimated that the cost of a new school, the site of which has been conditionally promised, will be £1,200.

WREXHAM.—A scheme for the erection of a church house and three churches in the district is estimated to involve an expenditure of £13,000. Messrs. Prothero, Phillott and Barnard, architects, of Cheltenham, are responsible for the whole of the designs.

Works in Progress and Completed.

BOLTON.—A new monolithic monument, shortly to be erected here as a war memorial, presented by Mr. George Harwood, Liberal M.P. for this town. The shaft, which has been cut from the granite quarries of Messrs. Duke and Co., of Merrivale, near Princetown, is 20ft. high, and has a base of 10ft. diameter. On the top of the column is to be fixed a bronze cross, and on the four sides of the square upon which the column immediately rests, are to be placed bronze shields, depicting scenes in the war.

BRADFORD.—The extension to the Town Hall is now proceeding at a rapid rate, and will probably be officially opened at the end of next month. The exterior has been finished for some considerable time, and the interior is now approaching a state of completion. Mr. F. E. P. Edwards, F.R.I.B.A., associated with Mr. Norman Shaw, R.A., is the architect.

CHORLEY.—An extension to St. Peter's Church, estimated to involve a sum of £3,500, is now proceeding. The scheme, which includes the removal of the chancel and the enlargement of the transepts, will provide additional accommodation for 306 persons.

CARDIFF.—The second of four workmen's institutes, provided by Mr. John Cory, was recently opened. The premises formerly used as a mission hall have undergone many structural alterations, the architect being Mr. William H. Scott, and the builder, Mr. Edgar Brown.

CATCLIFFE, NEAR ROTHERHAM.—The foundation stone of the new church, which is to be dedicated to St. Mary, was recently laid. The church has been designed in a free Gothic style by Mr. J. E. Knight, of Rotherham, and, when completed, will accommodate 300 people. The estimated cost of the building, including furniture, but excluding the organ, is £3,000. The contractors were Messrs. Thomas Roper and Sons, of Sheffield.

DUBMIRE, NEAR FENCEHOUSES.—A new workmen's institute has been erected here. The architect is Mr. W. Pallister, of Philadelphia, and the contractor Mr. R. H. Harrison, of Houghton-le-Spring.

HUDDERSFIELD.—The new Palace Theatre recently opened here has been designed by Messrs. Richard Horsfall and Sons, who are also the architects of an almost identical building at Halifax. The new theatre will seat, roughly, about 1,600 people.

HURSTPIERPOINT, SUSSEX. — The foundation stones of a new Wesleyan church were laid here recently. The church will accommodate about 150 people, and a schoolroom at the back will seat another 100. The contract, which is in the hands of Mr. King, of Hurstpierpoint, amounts to £1,350.

LONDON.—It is stated that Messrs. Wm. Arrol and Co.—the firm that has been employed upon the Blackfriars Bridge extension—are likely to gain about £3,500 in bonus. This has been brought about by the expeditious way in which the work has been carried out, whereby the authorities forfeit £20 for every day from the conclusion of the work to the expiration of contract time. The work is now practically complete, all that remains to be done being the repaving of the old part of the bridge; and by the end of the present month, or at latest the first week in September, the widened bridge will be available for traffic. With the present addition of 30ft. the width of the bridge will be 105 ft. between parapets, making it the widest bridge across the Thames. The new roadway is 73ft. wide and the footpaths each 16ft. wide. The whole of the bridge has been repainted. With the exception of the shore span on the northern side, the old face ribs and parapets have been utilised for the new western arches, and the methods employed for moving these huge masses of material, weighing 120 tons, from the old to the new site without dismantling show great ingenuity. The subways now under construction at the northern end of the new bridge will also be completed at an early date. The scheme adopted provides for two shallow subways between the Thames Embankment and Queen Victoria Street, each 10ft. wide and 8ft. high. The more important subway, that from the Embankment to the corner of Bridge Street and Queen Victoria Street, is completed except for the tiling; work on the second subway should be finished within three months from the present time. The difficulties of the work have arisen out of the necessity of diverting two 24-inch and other large gas mains of the Gas Light and Coke Company, as well as water mains. In connection with the second subway it will be necessary to reconstruct the crown of the Fleet sewer and to divert the main supply cables of the Charing Cross, West End, and City Electricity Company.

MIDDLESBROUGH. — Works to be known as the Ormesby Rolling Mills, on land to the south of the Cargo Fleet Ironworks, are now in course of erection.

NEWCASTLE.—A memorial to the late Bishop of Newcastle (Dr. Arthur Lloyd) was recently unveiled in St. Nicholas' Cathedral. The design of the tomb, together with the necessary alterations to a carved screen, was entrusted to Messrs. Oliver, Leeson and Wood, architects of Milburn House, Newcastle, and the work has been executed by Mr. R. Beale, also of that city. The recumbent figure, the outstanding feature of the memorial, is the work of Mr. F. W. Pomeroy, A.R.A.

NEW INN.—The foundation stone of a new Wesleyan church, which is being built here, was recently laid. The edifice is estimated to seat about 130 worshippers. Mr. D. C. Udell, Pontypool, is the architect, and Mr. W. H. Campbell, Pontypool, the builder. The scheme is expected to cost about £500.

ROSYTH.—Work in connection with the erection of a large model lodging-house or working men's hotel at Jamestoun, near Rosyth Naval Base, is temporarily at a standstill. From £10,000 to £12,000 was set as the cost of the building, which was to be four storeys in height, was to provide accommodation for 600 lodgers. The building contractors were Messrs. J. J. and P. M'Lauchland, Larbert, and they have withdrawn their men and plant from the work. Labour and material have been expended on the work to the value of between £2,000 and £3,000, the outside walls having reached the second storey.

RAMSEY.—The foundation stone of the new Catholic Church of Our Lady of St. Maughhold's has been laid. The church stands in a commanding position on the Ramsey Promenade, along with the presbytery and tower. The total cost will reach over £4,000.

SEAHAM.—Foundation stones of the new Stewart Street Primitive Methodist Church at Seaham Harbour have been laid. The new church will have seating accommodation for over 300 persons, and, later, school premises will be added.

In the 32nd annual report of the Society for the Protection of Ancient Buildings the committee draws attention to threatened destruction of ancient houses in Bath Street, Bath, and expresses its deep regret that the City Council should have given its consent to a scheme which will result in the practical destruction of the houses on one side. The works of repair to the stonework of the upper storey of the college houses at Eton are approved. As the result of an inspection of the works in progress at Glastonbury Abbey, the committee considers that the repairs which so far have been carried out at the ruins are necessary for their preservation. It feels, however, that the more the use of new freestone is abstained from in such works the more harmonious is the final result, as dressed ashlar strikes a discordant note, which with undressed stone is not the case. The rector of St. Margaret's Church, Walmgate, York, has informed the society that nothing definite has been decided with regard to the ancient sculpture in the porch of that church, which, according to a statement in the Press, was to be substituted by modern sculpture made in imitation of the original work. The committee urges that the old work, even in its weather-worn state, would be infinitely more valuable than a "restoration" under best conditions, and expresses a hope that the necessary £30 for this purpose will be promptly subscribed. Burnham Ulph Church, Norfolk, which appears to have been built in the thirteenth century, has had its original character and appearance destroyed. Some years ago the roof was renewed in pitch pine, and the two windows in the south wall were rebuilt with new stonework. Among other buildings reported upon are Ashwell (Herts) Church tower, Barrington Court, Somerset, Bolsover Castle, Derbyshire, Town Hall, Cirencester, Donington Church, Lincolnshire, Dymchurch Church, Kent, Fincham Church, Norfolk, and Heston Church, Oxon.

THE R.I.B.A. EXAMINATIONS & RECENT MODIFICATIONS.

The number of queries which have reached us respecting the alterations recently made in certain subjects of the R.I.B.A. examinations leads us to believe that it would be useful to student readers of this Journal to give some advice and information under the above heading, but we would at the same time add the caution that it cannot yet be said that finality has been reached either in the form or scope of the various subjects.

Generally it may safely be said that a candidate carefully prepared to enter the examinations in their original form would have but little difficulty in passing the same examinations as now amended or under any further probable modification. In other words, the scope of the examination is not increased, nor the difficulty of satisfying the examiner greater, if one may judge by the first set of questions under the new rules.

The chief points of difference from former papers lie in the form which the questions take and the division of the subjects, the latter being now less cumbersome and more simply classified, while in the former there is now more scope for literary ability, and, in consequence, probably a little less premium upon "clever" draughtsmanship.

There is at present no indication at all of any tendency to alter or modify what may be called the "science" part of the examinations, either intermediate or final, nor is it probable that any essential alterations can be made except such as are due to the modifications in method which are constantly taking place under modern conditions of construction. For instance, just as hitherto the methods required in the examination for the calculation of steel structures have been only such as the average practitioner of architecture could reasonably be expected to carry in his head—the methods of the engineer being rather discouraged than otherwise—so in dealing with reinforced concrete work the examiners appear to regard the principles involved as of greater importance than any detailed knowledge of the formulæ employed—the latter have not been required up to the present even in their simplest form.

In applying a closer scrutiny to the modifications it will be well to analyse the questions recently set in the summer examinations, and for this purpose to divide the subjects into two parts, dealing first with the intermediate; but before we proceed to do so, it might be well to call attention to the supplement to the R.I.B.A. Journal, recently issued to members of the Institute, in regard to the proposed reconstruction of what may be called the Examination Department. As all intending candidates can obtain access to this supplement, it is hardly necessary to recapitulate the proposals therein made; moreover, any further modifications affecting candidates are not at all likely to come into force during the next two or three examinations; again, it may further be safely said that it cannot even then make any serious differences in their chances of success, provided that they have a reasonable knowledge of their profession in its "æsthetic" and its "scientific" as well as in its "business" aspect. Practice and methods of routine can only change imperceptibly; the science of construction rests on fundamental principles, which can only be changed in the sense that knowledge increases from day to day: the Art of Architecture can only be modified to suit the gradual changes made to meet modern needs, and must always be founded on the same undying principles exemplified in the finest examples of past "styles."

Referring now to the questions recently set, we find that there are still four papers in the Art section and three in the Science section; of the first four papers the first three deal with the history of the styles in chronological order, the fourth being a general paper which embodies the new principle, viz., "The purpose of Architectural features in relation to the Buildings in which they occur." The whole arrangement of this subject is obviously a great improvement on the former method, and the modification would be sufficiently justified by the inclusion in one "subject" of the whole of classical architecture on the one hand, and the coupling in the second subject of the European with English Mediæval Architecture instead of the former arrangement (Renaissance being now more logically kept distinct and alone in the third paper), even if it were not to emphasise also the "Purpose of Features." The set of papers is now obtainable from the Secretary R.I.B.A., No. 9, Conduit Street, W., in pamphlet form for 1s., so that reference will only be made to the questions by number. No notice will here be taken of the questions set expressly for relegated candidates. Paper I.—Questions 1 to 5 were for relegated candidates. Question 6.—This question is of a critical and analytical character, but involves only such knowledge as was formely required, and might be answered by any candidate possessing a knowledge of the plan and general arrangement and construction of parts in the Parthenon, such as may be obtained in the usual text-books. Question 7.—This question calls for a knowledge of the details of skyline and profile in section of the Orders and Temple buildings generally, and a careful analysis with freehand sketches of the usual external ornaments, such as the acroteria, antefixæ, etc., would form an important part of the answer calling attention to the constructive points emphasised thereby: contours of the principal mouldings showing how weathering and drips were obtained would also be useful. Question 8 is really an extension of Question 7, and the same general knowledge is required, but in this case the need for historical information as to actual examples is emphasised.

It is noticeable that in this paper, with the exception of parts of the first five questions which were primarily intended for relegated candidates (though they were permitted as an alternative to any candidate who preferred to take them), no attention whatever is paid to Roman Architecture, but it is quite conceivable that on another occasion the position might be reversed; and the moral, from the student's point of view, is not, we think, that Grecian Architecture is more important than Roman, but that every candidate is expected to be fully conversant with each branch of the subject. We shall have some further remarks to make about this feature of the R.I.B.A. examinations in dealing with Subject VII.

Subject II.—Mediæval Architecture.

In this and the following papers no special questions were arranged for relegated candidates: from this it may be seen that in the view of the examiners, those who had prepared to be examined under the old system should have been capable of making a satisfactory attempt under the new—in other words, that the knowledge required was not regarded as being greater nor essentially different; those candidates who had already passed in part of the subject under the old regulations were informed that only a low percentage of marks in this and the following paper would be required.

Question 1.—This question may be called a "stock" question in a slightly different form —every candidate should be able to sketch and discourse upon the various forms of Gothic window arches; but again it is noteworthy that actual examples are preferred, and this should emphasise the great importance of sketching and measuring from the work itself rather than from drawn examples alone.

Question 2.—This is a "rider" to the first question, and requires additional knowledge of detail, mouldings, and constructive masonry.

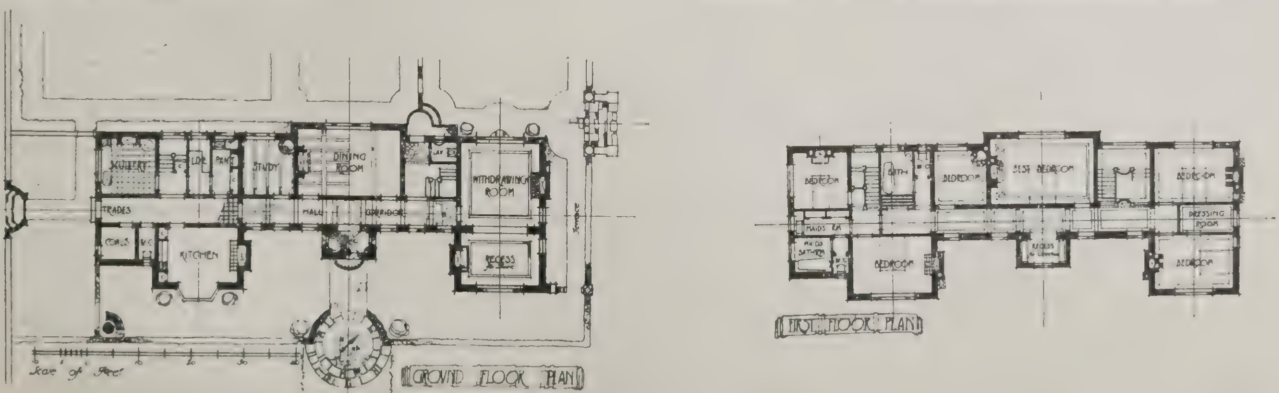
Question 3.—This is just such a question as frequently occurred in Subject IV. of the old regulations, and is perhaps of a more advanced type than the last, but should, none the less, be quite within the powers of a student of average capability, who has used his analytical faculty in comparing two or three of the Tudor examples with those which went before. The "illustrative sketches" are again required.

Question 4 is more on the lines of questions 1 and 2, and involves only the elementary knowledge of typical details which would be readily obtained by a day or two conscientiously spent in sketching small details from three churches typical of the Gothic "Periods."

Altogether it may be regarded as an eminently fair paper; only one question out of four needs special knowledge or treatment.

Paper III.—Renaissance Architecture.

This paper is distinctly simpler than the type of paper formerly set under the subject known as "Outlines of Mediæval and Renaissance"; for instance, in the first and third questions great latitude is allowed, for in the first question every student of architecture should be able to give a tolerable sketch of a façade of one at least of the many examples in almost any district in England of Jacobean manor houses, or, failing this, of some French Renaissance façade; nevertheless, most of those who entered for the examination seem to have taken refuge in the third alternative, and given a façade of one



HOUSE AT WEST BYFLEET, SURREY. PLANS. CASTLE AND WARREN, ARCHITECTS. (*See Centre Plate.*)

of the Florentine or Venetian palaces. In the third question, Brunelleschi, Palladio, Michael Angelo, and one of the Mansards, were probably the most frequently chosen. In the second question the word "perspective" sketch caused a good deal of trepidation, but it is not an unusual form for the question to take, and of course it is only a sketch roughly drawn in perspective that was wanted; it is a striking instance of the want of the power of accurate observation among those by whom such a habit should be most carefully cultivated, that many London candidates chose rather to draw the Italian feature than the London steeple; prospective candidates resident in London would be well advised to take a very great deal more trouble to study the numerous examples of architecture immediately around them rather than rely solely upon a book knowledge of foreign examples; if books alone are to be the source of information we would urge the importance of referring to the larger works, obtainable at the A.A. and R.I.B.A. reference libraries, or to the large plates of measured details that are published from time to time in this and other journals; let us also emphasise the importance to every architectural student of forming a collection of such plates for himself, as the very fact of searching for and arranging such illustrations helps materially to impress the building itself upon his mind, indeed, next to actually visiting and measuring the building, this is perhaps the most valuable source of study in the historical side of the subject. The last question in this paper is a very favourite one with the examiners in one form or another; for instance, in the Model Answers to the R.I.B.A. examination papers that appeared in this Journal during 1906, a very similar question occurred. Of course, the three periods in which the effects appeared most evidently were, first, during Henry VIII.'s reign, when he brought over Italian workmen for his father's tomb; secondly, during Jones's life, when Palladio's works were exerting a great influence on English work; and thirdly, when Wren returned from his studies in France deeply influenced by Vignola's teachings.

Paper IV.—General History of Architecture and the Purpose of Architectural Feature in Relation to the Buildings in which they occur.

This was the paper that probably aroused most interest, as it was in this, ostensibly, that the new subject was to be first treated, although in reality for some years past the questions have been becoming, generally speaking, far more critical, and the principles involved have been touched upon, as well as the historical or archæological facts; a knowledge of "Origin and Development" has often been required, and in other respects also there were few innovations in this paper; certainly a selection of only four out of six questions allowed ample choice, and this is a precedent that might probably be wisely followed to a somewhat greater extent than in the past. Dealing with the questions themselves, the first one, of course, was meant to bring out the fact that in Italy the Renaissance movement was rather a revival of the Ancient Roman architecture, tinged with Byzantine influence, than a development of the Gothic, which had indeed always been a foreign growth without much root, and which really brought far less influence to bear on the Renaissance than it did in the Northern Countries of Europe, where it was indigenous.

The second question is really in strong contrast to the first, and covers a very wide field; it was, of course, the arch compared with the lintel construction, and the *emphasising* compared with the *hiding* of constructive detail, the general necessities of the plan expressing themselves naturally in the elevation compared with strict symmetry often over-riding the utilitarian needs of the plan. The third and fourth questions can be taken together, the Byzantine style being the Eastern architectural development during the period mentioned, and being compared with what is known as the Early Christian work in Italy itself.

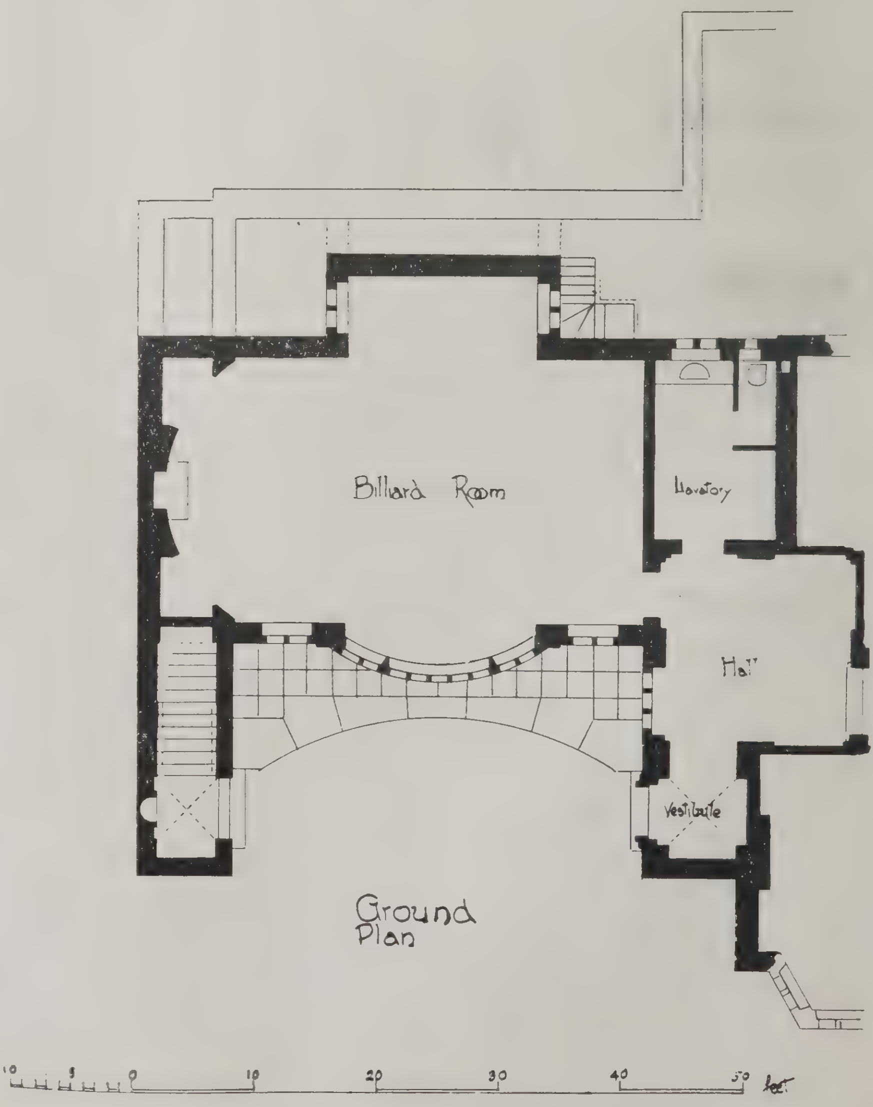
The fifth is a question which often used to occur in the "Outline" paper under the old order of things, and an answer can be found in the series of model answers already referred to. The last question should have given no trouble to anyone interested in his studies, and it encourages a critical observation of the buildings around one which is greatly needed among students, as has been hinted before; it is generally much easier to find a building we admire than to give our reasons for our preference, and it would be a good thing, in view of such questions, for intending candidates to read such a book as Mr. Belcher's, on "Essentials in Architecture."

The rest of the papers and those set in the final will be treated in a further article.

Societies and Institutions.

The Junior Institution of Engineers.

The summer meeting of the Junior Institution of Engineers in the Midlands opened on Saturday morning last, at Leamington, with a welcome by the Mayor Councillor, Alfred Holt, J.P. In the afternoon Warwick Castle was visited, and in the evening there was an illuminated concert in the Jephson Gardens, by invitation of the Town Improvement Association. On Monday morning Messrs. Muntz's Metal Works and Messrs. Joseph Gillott's pen manufactory were visited; in the afternoon the James Watt Museum. Yesterday morning the members were received at Redditch by the Birmingham local section of the institution, and visited Messrs. Shrimpton's needle manufactory, and Messrs. J. Warner and Sons' fish hook and fishing tackle manufactory. In the afternoon the Shakespearean features of interest at Stratford-on-Avon were seen. To-day will be occupied in a visit to the mechanical, electrical, and civil engineering departments of the Birmingham University, the afternoon being devoted to visits to the Austin Motor Co.'s works, and the works of the Birmingham Small Arms Company. To-morrow (Thursday) Coventry will be visited, the morning being spent at Messrs. Herbert's machine tool works, and those of the Triumph Cycle Company, and the afternoon in visiting the new gas works of the Coventry Corporation at Foleshill, and Messrs. Rotherham's watch factory. Messrs. Cadbury Brothers entertain the members on Friday morning at their Bournville Works, and for the afternoon Messrs. Elkington's electro plating works will be open for visiting. The Institution's summer dinner takes place in the evening at the Great Western Railway Restaurant, Birmingham, and on Saturday morning the Summer Lane Electricity Works of the Birmingham Corporation will be seen, the afternoon being occupied with a visit to the electric signalling apparatus of the Great Western Railway at Snow Hill Station.



ADDITIONS TO BRANDON, SHEFFIELD. EDGAR WOOD, A.R.I.B.A., ARCHITECT.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

Steel Concrete. "Ferro-Concrete" is a term that might be more appropriately applied to such a composition as that described recently by Mr. Leon S. Moisseiff rather than to reinforced concrete in the general sense. It will be understood how by the incorporation of a large proportion of steel wire nails, steel wire and scrap iron in cement and sand mortar, the compressive resistance was enormously increased. The cost of such a material is very considerable, but it has its uses. The strength developed in the tests was very remarkable, and a wonderful increase over plain concrete occurred at the short period of seven days. The highest stress developed was 17,800 lbs. per sq. in. on a 6in. cube 15 months old, while some 12in. cubes could not be broken in the machine, and tend to show that the material will show still greater strength in bulk. Failure in compression is nearly always failure in shear, and these tests demonstrate this very forcibly. The reason why the steel nails increased the strength of the concrete must obviously have been by strengthening the material against internal shear stresses. We seem to be learning something new about concrete every day, and reinforced concrete construction as it develops throws interesting side lights upon the structure and properties of all materials. The experiments on spirally-hooped columns described in our columns about two years ago by M. Considère, also have their bearing upon this problem. It was then shown how the application of hydraulic pressure to the outside of a specimen under vertical loading increased the shear resistance of the piece, in just the same way as the spiral hooping. That is another way of strengthening the concrete against the shear stresses that destroy it in crushing. The compression specimens are usually made in the form of cubes, but these should be higher so as to allow of the material shearing normally. The resistance developed by a proper specimen (the height of which should be 1½ times the length of the side) is less than that obtained from the cube. That, however, is only an incidental feature, though it has its bearing on the subject of shear stresses. Some experiments, too, conducted by a specialist, in which columns had ties across the section as diagonals, as well as the ordinary circumferential ties. These diagonal ties seemed to develop the strength of the core. And no doubt their action was to increase the shear resistance. The above-mentioned experiments with nails should now be supplemented by further experiments on a more extended scale, so as to thoroughly elucidate the internal stresses, to determine the modulus of elasticity and other interesting problems. We may very probably be on the eve of most important discoveries that may transform the manner of constructing structures of other materials, as well as of concrete.

Moulded Lumber. In the United States we find various ideas being worked out in many ways. In that country inventors are encouraged to develop every idea, however absurd it may appear at first sight. Ideas are not put on one side for want of consideration, or experiment, if necessary. Every possibility of working in concrete that may occur to anyone is tried. Novelties are not immediately discredited because they appear to be possibly inefficient, or do not show economy over ordinary methods. Thus when, as generally, exploited by enthusiastic inventors who manage, one by one, to overcome the difficulties, and it is discovered that what appeared to be an absurdity or an impossibility was, if modified and properly carried out, an eminently practical idea, and one that was distinctly advantageous as regards economy of time, material or labour.

One of the directions in which considerable efforts are being made to perfect the principle is in the construction of parts of construction by separately moulded pieces. Instead of executing the work *in situ*, reinforced concrete buildings of various kinds have been erected in which many of the members were moulded separately and put in place, very much as timber might be. As a rule, such construction has not been found to offer any advantage, except in the way of speed, over the methods of completely erecting a structure of centering and casting the concrete thereon. Such centering is, however, expensive, and it is possible by the use of moulds to do away with a large amount of it, and if only means could be found to design and erect the moulded pieces economically, there is undoubtedly a great future for the system.

Our readers will remember how Mr. Thos. Edison proposed to pour a concrete house within a metal mould. In this case, however, he would have had to erect the moulds first, which thus was practically the same as an ordinary wooden centering, although the moulds were more lasting.

Another system of building, however, which is already in full swing in the States seems to us to offer more chance of success than Mr. Edison's proposal. In this system the walls are cast flat upon the ground, and are then raised into position by a special form of screw-jack, consisting of a kind of tilting frame. The walls are then coupled together and the floors and roof affixed.

In another system, stanchions, joists, roof, principals and rafters, walls and tiles are all made up of moulded elements, which are assembled together very much as timber is. Though it would appear that timber was very much more economical yet concrete can, however, be cast, where there is plenty of repetition, very cheaply, and its lasting qualities and fire-resisting nature are, of course, infinitely superior to timber, so there is sometimes a saving effected even in house construction, if all these points are considered. The system at present appears to us to be too ingenious and too complicated to promise any real success in its present form, but no doubt in the course of time it will be much simplified as the results of practical experience. We now find that sleepers and fence posts are economically made of reinforced concrete, and, indeed, it is being used for all sorts of strange purposes, so that we must not be surprised if this method of construction with separately moulded concrete pieces becomes an economical method in the near future, and supplants in some part the moulding of work *in situ*.

Concrete Notes.

The concrete plant for storing, mixing, and transporting the materials for the construction of the Gatun locks of the Panama Canal has excited a great deal of interest on account of its unprecedented size and its many unusual features. The general design of construction plants for concrete work, even of large size, is so familiar to engineers interested in the subject, and the equipment commonly used for definite classes of work follows so closely to what may be termed standard lines, that the size of the equipment now in operation at Gatun is rather surprising. In the first place, the storage capacity advisable for the concrete materials was necessarily large, so that the work would not suffer by delays in the delivery of material, and the provisions for the storage of 200,000 cub. yds. of crushed rock, 100,000 cub. yds. of sand, and a maximum of 120,000 barrels of cement, are well within the requirements when considered in conjunction with the high yardage of concrete to be placed each day. Only a meagre acquaintance with construction work is necessary to appreciate the magnitude of these storage figures. Possibly, however, a figure that will appeal still more to practical men is the daily rate at which concrete will be deposited; a maximum rate of 2,220 cub. yds. in each 9-hour shift is expected in those parts of the work where only a little form work is required. These figures are so large that they must be compared with the daily rates usually attained on large dam and lock work in order to be appreciated. The total quantity of concrete to be placed is between 2,000,000 and 2,300,000 cub. yds., and this is to be distributed along a distance of about 3,900ft. Bearing these figures clearly in mind, the duties of the mechanical equipment are more readily comprehended, and the necessity for high speeds in cableway and electric railway operation is seen. The transportation of the mixed concrete along the lock, previous to delivery to the placing cableways, was in itself a problem of no small magnitude, and steam motive power, so commonly used for this service, has been laid aside, and a third-rail electric railway adopted instead. There are eight cableways, four duplex machines of 800-ft. span, carrying two-yard buckets at a maximum speed of 2,400ft. per minute, and depositing as much as 2,200 cub. yds. of concrete in 9 hours.

* * *

The effect of concrete in preventing the rusting of steel imbedded in it has been the subject of so much controversy that the light thrown on the matter by the electrolytic theory of corrosion is instructive. According to this theory, iron can pass into solution only when an equivalent amount of hydrogen passes from the ionic to the gaseous state, and if the hydrogen concentration is reduced the rusting of the iron will be diminished. This is achieved by adding a strong alkali to the water which is in contact with the steel. According to Dr. W. H. Walker, the caustic lime given off by Portland cement in setting and hardening has this action, and iron or steel imbedded in concrete will not rust so long as this caustic lime is present. Unfortunately it is soluble in water, and it is therefore desirable to make the concrete containing steel reinforcement very dense since by so doing the protective properties of the concrete will be maintained for the longest time. If the caustic lime is once dissolved out of the concrete, the metal will surely rust, according to Dr. Walker. This theory is completely in accord with experience, which has shown that dense concrete will protect steel, even when it was rusted before being embedded in the material, while in porous concrete steel will sometimes rust rapidly.

The late Mr. John Wornham Penfold, of Courts Hill, Haslemere, Surrey, architect and surveyor, for many years secretary to the Surveyors' Institution and surveyor to the Goldsmiths' Company, left estate of the value of £62,071 gross and £49,076 net. The testator left £500 to the Surveyors' Institution and £500 to their benevolent fund, £2,000 to Haslemere Cottage Hospital, £200 to the Royal Surrey Hospital, £150 to the Charitable Fund of the Surveyors' Club, £100 to the Benevolent Institution of the Royal Institution of British Architects.

REINFORCED CONCRETE.

By Arthur C. Auden.*

Reinforced concrete is *not* the "new thing," the "experiment," the "unknown quantity" which it is so frequently and erroneously described as being. Of course there are new forms and uses of it which we have not yet been able to test by time as to their durability, but these only represent phases of the development of the material as a whole and do not affect the main question of depreciation, upkeep, reliability, and similar important matters. It is a fact well known to all those who have studied this question, even superficially, that there were important structures in reinforced concrete erected in London in 1889, and which are still in use, and on the Continent can be seen equally large structures successfully built twenty-five years ago and also still in use without having been strengthened or "patched up." It may probably be said that the above instances, being buildings or houses, are not very conclusive evidence to engineers, as they would probably never be loaded up to even the safe loads for which they were designed, and the area of their foundation-plan is practically equal to that of the buildings themselves, and also that they are not subjected to much vibration. We will therefore take the case of bridges, which are subjected to great vibration and the foundation area of which is very much less than that of the whole structure, and we find that there are numerous instances of bridges in reinforced concrete built more than ten years ago which are still in as good, or better, condition than when first put up. I do not refer to narrow-span bridges or culverts, but to those of fair spans such as the Eslingen Bridge over the river Neckar with a 60ft. span, fourteen years old, and over the same river at Ybbs with 140ft. span, twelve years old, the Chatellerant Bridge, 153 ft. span, eleven years old, and the Prince Rupert Bridge at Munich with 191ft. span, and ten years old.

Materials.—An important point in connection with reinforced concrete frequently presents itself, namely, as to the nearest place where the materials, such as sand and gravel or chippings, can be obtained, and it is a question well worth close consideration because in nearly all instances the cost of the proposed structure will be of course affected by the cost of its constituents, and these are in turn much influenced by the cost of freight and carriage. From this particular standpoint it is proposed briefly to classify the materials, as it is by no means uncommon to find that, within reasonable limits, we can, by slightly altering our design, use cheaply-obtained aggregates without in any way materially affecting the use and efficiency of the proposed structure, provided of course that the said structure is not of an ornamental design and does not contain much fine work.

From the above standpoint, therefore, I will consider, first, the stone, that is, chippings or gravel.

In many places the Eastern Counties' flint is practically the only stone locally obtainable but though this makes good, tough concrete, it is unreliable for fire-resisting purposes owing to its tendency to crack and "fly" under heat. The proposing user must, therefore, balance his reduction in capital expenditure by a slight increase in his fire-risk. It is interesting, however, to know that this tendency to crack under heat can be much reduced by passing all the stones through a crusher, as practically all flints have their crystallisation definitely bounded by planes along which they always break, the remaining portions between such planes being comparatively homogeneous with but little tendency to "fly."

The same remarks apply to limestone, but it has not the redeeming feature of being more fire-resisting after being broken; in fact, it is not advisable to be used at all where fire-resistance is an important consideration, as it is very apt to disintegrate to powder under the action of heat, but it is not to be condemned entirely as it is quite a serviceable material apart from increased fire-risk. It must, however, be remembered that it almost always needs washing before use, as, after breaking, it will generally be found to be covered with fine, blunt dust which prevents the cement properly bonding with it; the expense of this washing must, therefore, be set against the cost of other slightly higher-priced stone which can be used as received.

Sandstone can be obtained in many parts of the country in almost unlimited quantities, but as a rule it is too soft, too porous and too absorbent for use in reinforced concrete work. Samples should always be taken and tested by crushing, and if it is found that it will stand about 1½ tons per square inch, and that the difference in weight, when clean and dry and after being two days under water, does not exceed 8 per cent., it may be safely used.

Quartzite stone is fairly good if not too soft and open in texture, in which case the same precautions apply as for sandstone.

With reference to testing for crushing strengths of either stone or concrete, it must be borne in mind that reliable results cannot be readily obtained by crushing small pieces, say of only about a square inch or so in area; it is always advisable to use larger test pieces, say such with an area of at least 10 or 12 square inches.

Speaking generally, broken bricks are not a good aggregate for reinforced concrete, although they have given excellent results in mass-concrete. They are usually too soft and yield too much blunt dust and have frequently old mortar adhering to them; if, however, they are hard and close in texture and free from mortar they may be safely used.

It is well known that coke-breeze makes an excellent class of concrete, but it must be remembered that such cannot be regarded as being really fire-proof, although some recent tests by the British Fire Prevention Committee, to which reference will be made later, show that this material can "hold its own" very well in this respect; but from its nature it is much less capable of resisting either tensional of compressive stresses than harder and tougher materials, and the question of sulphur is also present. It is, however, quite possible to design a structure in such a way that—omitting the question of the best fire-resistance—a large portion of it can be made with reinforced concrete composed of this usually cheap and readily-obtained aggregate.

There are very few manufacturers or mechanical engineers who do not make ashes and clinkers, and many have to pay to have them removed. It is, however, quite possible, with care, to obtain two decidedly serviceable forms of aggregate from these, one being the ashes, which are very similar to coke-breeze, and the other the hard-burnt clinker; but, as with all other materials except the real stone aggregates before-mentioned, discretion must be used in the selection of any which are derived from waste products, such as are now under consideration.

In the case of ashes, only those that will float in water and which are of a uniform colour and texture, and quite free from adhering pieces of coal and dirt, should be used, while with clinker only that which is really hard and clean is serviceable. In both cases if the washing and riddling or screening are carried out as one process, a more reliable result will be obtained. The question of sulphur must, however, be carefully watched.

Slag from furnaces, whether blast or cupola, makes also quite a good aggregate, provided it is hard and tough and free from dust and its sulphur contents carefully noted.

As is well known, all clinkers, breeze, slags, etc., contain a certain amount of sulphur, which is apt to attack the reinforcing steel with disastrous results. The maximum allowable percentage of sulphur in reinforced concrete aggregates is now being made the subject of tests and experiments—as in fact are all other details in connection with reinforced concrete—and it is to be hoped that an authoritative statement on this subject will shortly be issued, as it is of considerable importance to engineers, particularly to those who have slag heaps of any considerable size, but there is an important point in connection with the presence of sulphur, namely, that if it is in the form of "sulphate" it is practically harmless, but if in the form of "sulphide" it is very deleterious, and anything more than a very small amount indeed should not be allowed.

Care should also be taken with all artificial aggregates that no free lime is present; but, as in the case of sulphur, there are two forms of this material present, one of the free lime referred to which is dangerous and the other carbonate of lime which is practically harmless. It must be noted, however, that washing and exposure to the air and sun will do much to convert the dangerous sulphide into the comparatively harmless sulphate, and exactly the same is true with reference to the harmful free lime and its practically safe carbonate. Unfortunately, quite good and accessible aggregates containing lime or sulphur are sometimes condemned *en masse* because no discretion is exercised as to the form in which such occurs.

Mention has already been made of the washing and screening of aggregates, and it may be of interest to note that "jigging" is a much better method than throwing against an inclined sieve or screen; it has the advantage also of enabling the washing to be done simultaneously with the screening, and also—particularly in the case of the artificial aggregates—jigging knocks the weak corners off and produces better shaped pieces.

Sand.—Sand is, in some parts of the country more difficult to obtain than any other constituent of reinforced concrete. A certain amount is absolutely necessary, and nothing up to the present is known which really and entirely supplies its place. Engineers having foundries will have a ready means of judging sand for reinforced concrete if they remember that, generally speaking, the better sand is for moulding the worse it is for reinforced concrete. For instance, it must not "bind," that is, retain any shape when compressed, and it must be incapable of being smoothed with a trowel to a bright surface, or of "standing up" by itself when cut with a shovel; these being "rough and ready" methods of ascertaining that the sand has what is required, namely, large sharp grains. Dirt in the form of slime, mud, or vegetable refuse is distinctly bad, but a little loam, enough to soil the fingers when lightly rubbing the sand between them, but not enough to make the sand itself adhere to them, is no detriment. Small particles or nodules of clay do not appear to affect the strength of the concrete, provided they are very small both in themselves and in number, but they are not an advisable ingredient and should be avoided if possible, unless there is ample time to mature and test sample pieces of concrete made with the sand containing them.

If sand is scarce or costly, some economy may be effected by regarding the very small pieces of the stone or other aggregate, below ⅛in. mesh, as sand, and mixing them with some real sand. The economy is not so apparent as appears at first because the small pieces must be screened out from the larger aggregate, and in most instances washed to remove the floury dust before being mixed with the real sand, ready for putting in the gauge boxes. It is not good practice to use the stone aggregate and its smalls and dust and some sand upon the chance that they will be in the proper proportions and that the voids and spaces will be properly filled. Experience has shown that this is usually not the case, and although this frequently is the practice with mass-concrete it should not be allowed in reinforced work where absolute homogeneity is so essential.

Cement.—With reference to cement there is nothing to remark, as most excellent descriptions of this material are obtainable anywhere, but it should not be one of the many mixtures imported into this country as *cement*, which do not deserve the name and are costly at any price. Any user is safe if he insists that his cement shall pass the British standard specification in every detail, and that it is purchased from a reliable manufacturer.

---

* Part of a paper read at the Liverpool meeting of the Institution of Mechanical Engineers.

(*To be continued.*)

CONCRETE PILES.

Reinforced concrete piles are now largely used for foundations in all sorts of structures and in many situations.. There is very little difference between the reinforced concrete pile foundation and the timber pile foundation. In general principle it is the same. The piles are driven in rows or clusters and capped with a platform of concrete on which the superstructure is erected in the customary manner.

In comparison with timber piles, reinforced concrete piles have several advantages and few disadvantages. They are equally durable in wet or dry soil, whereas timber piles must be constantly under water to have any life, and then often they are open to the ravages of the toredo or the limnoria—the marine borers—which make their life very short. In waters which are much infected an untreated timber pile may not last eight months, while a creosoted pile, even, may only last a few years. Timber piles are very frequently injured in driving, and it is surprising when they are exposed in subsequent excavation work as sometimes happens what a large proportion of piles are found to have been injured in the driving. Sometimes they are telescoped and sometimes the points turned up. Indeed, instances have occurred where timber piles have turned up in the driving, and the points made their appearance on the surface again. Now the reinforced concrete pile cannot be injured by hard driving, all that has ever occurred when attempts have been made to so injure them is for a short length at the bottom or top to be shattered, but the intermediate portion is always found perfect. Reinforced concrete piles are often drawn and redriven several times without any injury. It is difficult to secure long timbers for piles that will conform to the specifications in point, etc., whereas the concrete pile can be moulded perfectly to the dimensions and form desired, and proportioned to the load it is intended to support.

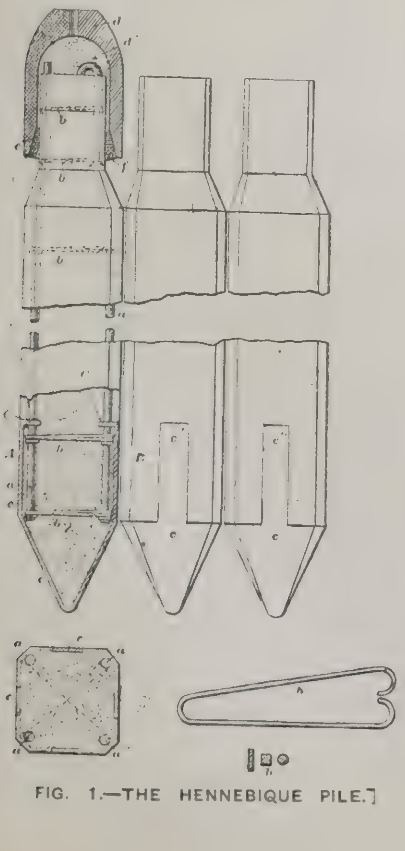

FIG. 1.—THE HENNEBIQUE PILE.

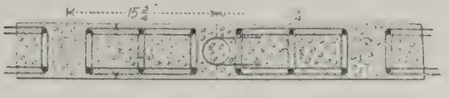

FIG. 2.—HENNEBIQUE SHEET PILING.

As regards first cost that is a matter in which reinforced concrete piles may be considered to be at a disadvantage, for such piles are generally more expensive than timber piles, though the position may be reversed in certain localities where the cost of timber is high. In this country there is not a great difference in cost. Other disadvantages are that reinforced concrete piles are more troublesome to drive than timber piles, and that they are heavier. To a great extent the first objection has been met by the employment of special pile drivers, while the second by making provision for lifting by special tackle. Even supposing the cost of reinforced concrete piles to be more than timber piles, there are other directions in which the cost is to a great extent set off by other savings. For instance, as the timber piles rot out of the water, it has been the custom to saw them off at low-water level and to erect piers from this point. This means that not only is there the trouble of cutting off the ends of the piles, but the depth of excavation and the quantity of superstructure must be increased.

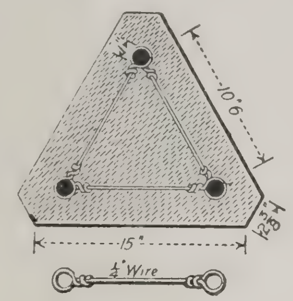

FIG. 3.—REINFORCED CONCRETE PILE USED FOR FOUNDATIONS OF A COURT HOUSE, BERLIN.

There are two main types of concrete piles on the market, one consisting of the reinforced concrete pile that is moulded in place and driven in a similar manner to a timber pile, and the other a pile formed of plain or reinforced moulded in place by pouring concrete down a hollow cylinder that is first driven in to the ground and afterwards withdrawn.

Reinforced concrete piles are very similar to columns, their construction consisting of vertical rods with horizontal ties. They have to be subjected, however, not only to the load acting centrally upon them in the same way as columns, but to sheer stresses induced by forces applied laterally and to vibratory stresses due to the driving, and to perhaps bending stresses due to their being lifted into position, the latter being of minor importance. The driving may be effected by means of blows upon their tops or by means of a water jet, which washes away the soil under their points. Sometimes the two methods are employed in conjunction. The water jetted pile is allied to the dropped pile; it sinks by its own weight, and does not need driving. Circular-pointed piles are perhaps best for penetrating in hard soils, but in softer soils the pyramid point is better.

There are various forms of reinforced concrete piles that have been invented and used. Fig. 1 shows the Hennebique pile, the general form of which consists of four rods placed at the corners of a square pile with wire ties between and a shoe attached to the ends, the whole being embedded in concrete, which is moulded either vertically or horizontally, though the latter method is usually favoured. The top of the Hennebique pile is circular, this being for the purpose of taking an iron cap packed with sand. In addition to this cap a timber dolly is employed to reduce the shattering effect of the blow upon the head of the pile. M. Hennebique's piles have been constructed with a circular hole moulded lengthwise down the pile, through which water can be forced by a jet, and finally for forcing grout out into the soil surrounding the point when it has penetrated as far as necessary.

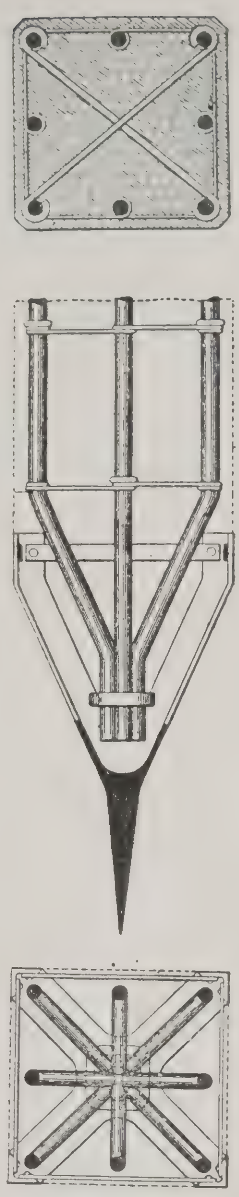

FIG. 4.—REINFORCED CONCRETE PILE USED FOR A WHARF, AT NOVOROSSISK, RUSSIA.

Hennebique sheet piles have also been constructed (as shown in Fig. 2) consisting of a rectangular slab with a steel-shod point formed by levelling one of the narrow faces so as to form a wedge edge with the opposite face. The reinforcement consists of six bars arranged along the broad faces, and tied together in the same way as in the square piles by loops of wire. A sort of tenon, formed of a strap-iron staple, was employed in the particular design here illustrated, so as to keep the piles in alignment while being driven. This staple also served to hold the nozzle in driving by water jet. The circular hole formed by the adjoining grooves was filled with concrete after the driving had been completed, and thus the piles were welded into what was practically a monolithic sheeting. A pile of a novel form is illustrated in Fig. 3. This, it will be seen, is triangular. It was used in the foundations of a court house in Berlin. The sides of the points were bevelled to form a point.

The reinforcements consisted of 1in. round rods at the corner, tied together with ¾in. wire ties at 8in. intervals. The rods converged together at the points and were welded together. The mixture of concrete employed in these piles was 1 part Portland cement with 3 parts river gravel.

Fig. 4 shows a form of pile that has been employed at Novorossisk, Russia. These piles were 15¾ins. square, and each carried a load of 85,584lbs. Their total weight per lineal foot was about 262lbs., of which the reinforcement constituted about 451lbs.

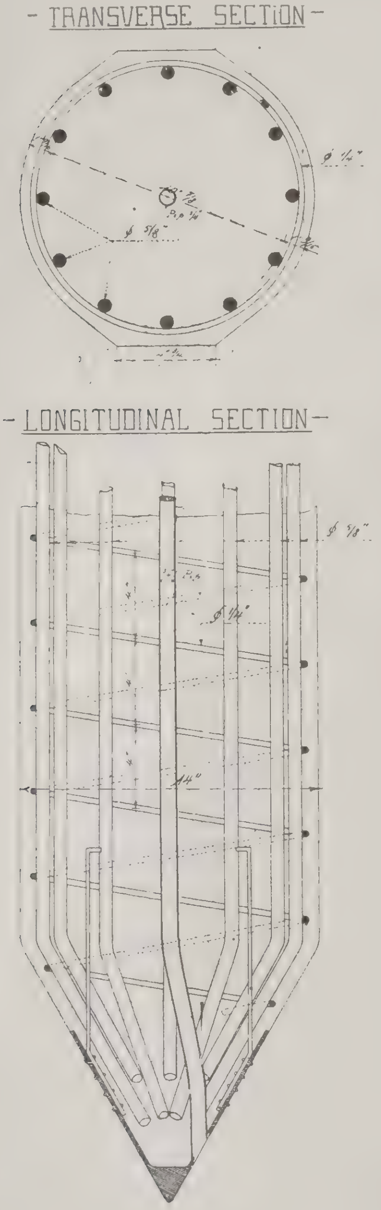

FIG. 5.—THE COIGNET PILE.

The Coignet pile (Fig. 5) has a larger number of longitudinal bars, with a rod spirally round them.

The Considère pile (Fig. 6) has also a large number of longitudinal reinforcements with spiral winding, but the former are smaller in section, while the latter is of larger section than the building of the Coignet pile.

A hexagonal hollow pile has also been designed by Signor Albertini, of Modena, in Italy, the purpose being to secure a light and strong pile, easy of transport and capable of being bonded with the superstructure by inserting rods in the hollow core and filling up with concrete.

A hollow pile of Hennebique manufacture, the invention of the late Mr. L. G. Mouchel, who was the first agent for the Hennebique system in this country, has also been used. Terra cotta tubes are here used and concreted in the pile.

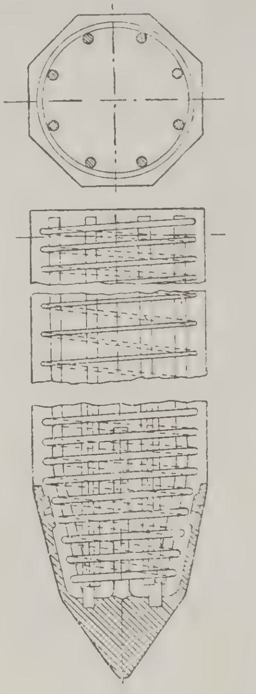

FIG. 6.—THE CONSIDERE PILE.

The Gilbreth, an American form of pile, is tapered and corrugated, and has a hole its full length through which a 2in. water jet pipe is passed while driving.

The Cummings is another American pile, octagonal in cross section, the longitudinal reinforcement of which is made of steel angles. The shoe is of malleable iron, riveted to the reinforcement.

Fig. 7 shows a peculiar form of sheet pile, in which the reinforcement consists of steel joists. One of the narrow faces has a groove and the other has a tongue to provide for the interlocking of the adjacent piles when they are driven as sheeting. These piles were used in a quay wall, and the anchor rod which is shown in the view was carried back in the filling of the quay and fastened to a massive concrete anchor.

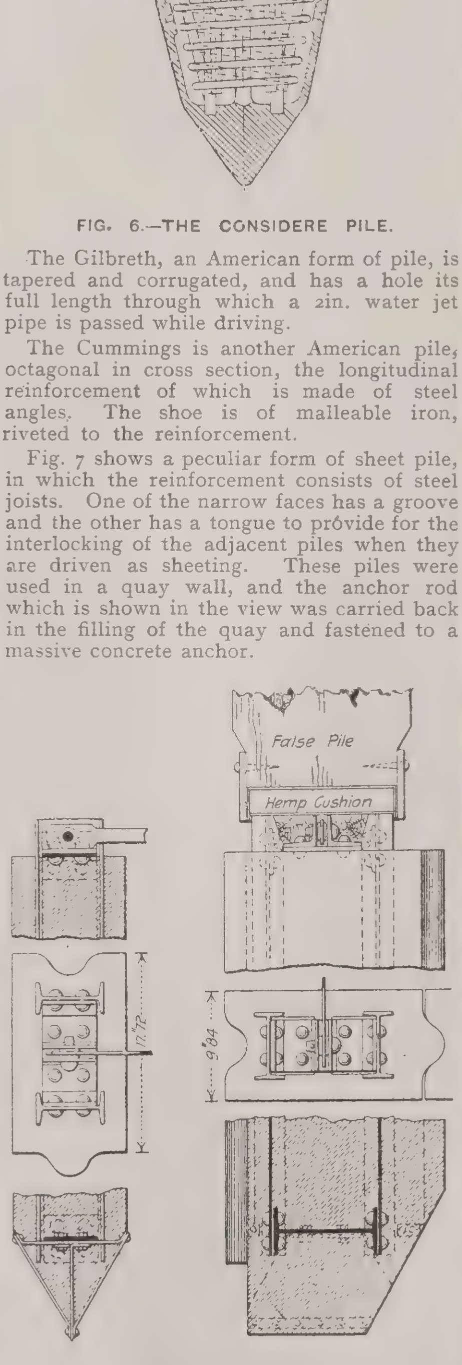

FIG. 7.—SHEET PILE WITH I-BEAM REINFORCEMENT.

Fig. 8 shows the Williams pile, which has a joist embedded at the centre, which is forged to the end to form the point; wire or hoop-iron ties are also provided to strengthen the concrete.

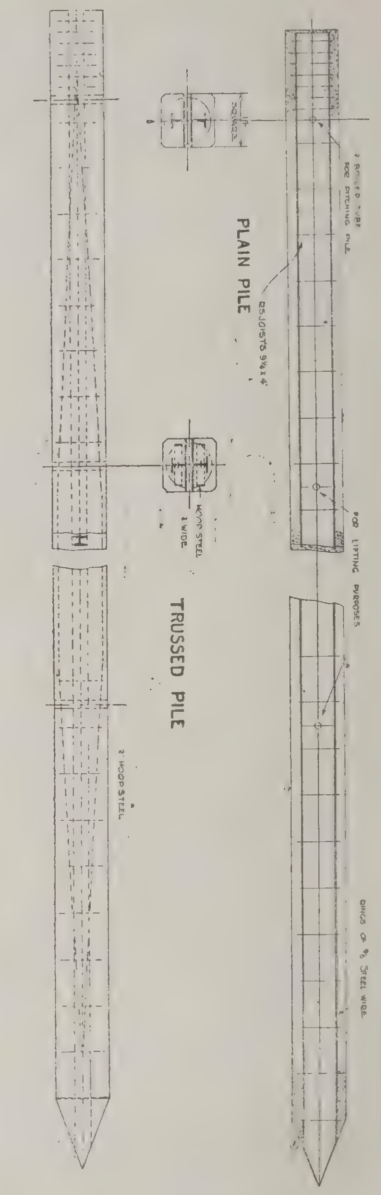

FIG. 8.—THE WILLIAMS PILE.

Some extensive pile foundations for a quay wall in a wharf were constructed at Southampton in 1898 by the Hennebique company. The piles in this quay wall were spaced 3ft. 7ins. apart longitudinally, and were 12ins. by 12ins. The bearing piles of the front, which were filled between with reinforced concrete sheet piles, each 12ins. by 12ins., were reinforced by 1⅛in. round rods connected by 3-16in. ties. The wharf 12in. by 12in. piles were spaced about 10ft. apart in both directions, and the wharf was designed for a load of 375lbs. per sq. ft.; each pile, therefore, sustained a load of about 570lbs. Four reinforcing bars, tied together at intervals, were used in each pile. The construction of the quay wall and wharf are shown in Figs. 9 and 10.

Reinforced concrete piles are cast either vertically or horizontally. It has been supposed by some that it is desirable to cast them in the former fashion, because that is the position they will occupy in the work. It has been found, however, that quite as good results can be obtained by moulding the piles horizontally, which method is much more convenient from a practical point of view, as it is more economical; indeed, it seems proved that a pile can be moulded much better in this position because the material can be punned better. The planes of the layers in which the concrete is moulded are, of course, vertical in the one case, and horizontal in the other, so that they therefore thus cross or are parallel to the direction of the pressure. Convenience in moulding horizontally seems to off-set any advantage

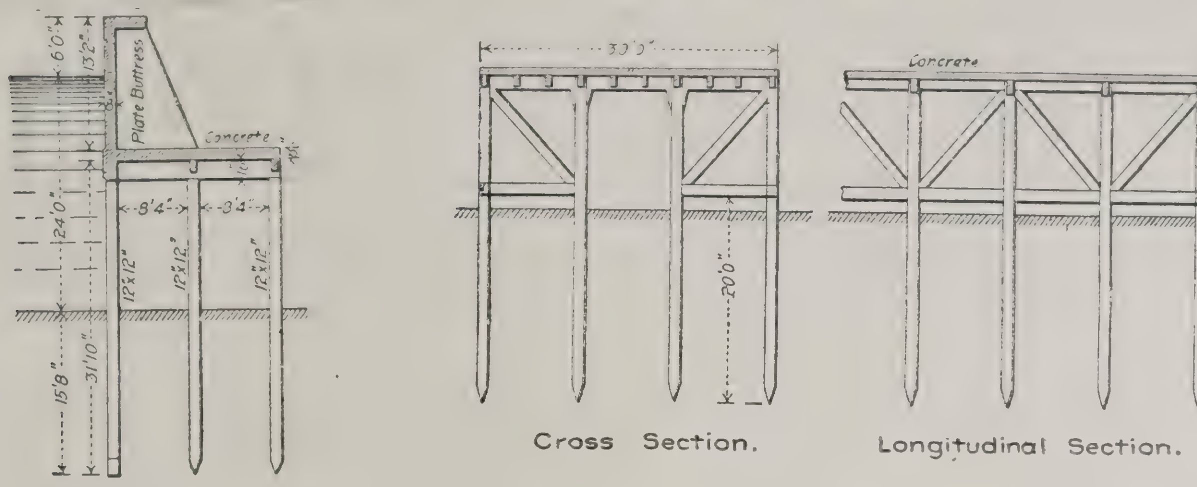

FIG. 9 AND 10.—REINFORCED CONCRETE QUAY WALL ON REINFORCED CONCRETE PILES, SOUTHAMPTON..

in this respect of the vertical method of moulding. The forms or boxings employed in moulding piles are similar to those used for constructing columns and beams. The piles can be removed from the forms in one or two days, but they are not sufficiently hard to be driven for at least thirty days.

Reinforced concrete piles can be driven by hammer pile drivers or by water jet, or in any other manner in which timber piles are driven. In driving by a ram, the fall of the ram is usually decreased, and some form of driving cap is provided to distribute the impact stress evenly over the top of the pile. The weight of the ram on the other hand is usually considerably increased. 16in. square piles of Hennebique construction used for a bridge in Alsace Lorraine were driven with a four-ton ram with a maximum drop of eight feet, which would decrease as the penetration decreased. Hennebique piles, 12ins. square, are frequently driven by a 30cwt. hammer, with a drop of 4ft. In driving sheet piling of 11.8in. by 14.8in. in cross-section, at Chantenay-sur-Loire, in 1898, a ram weighing 3,520 pounds, and having a drop of 6.25ft., was employed. The pile used in Russia, to which reference is made above, was driven 2ft. into a hard bottom, with from 10 to 14 blows with a 3,375lb. ram. Except that stronger tackle is required to handle the heavy reinforced concrete pile, the ordinary pile driving rig for driving timber piles is all that is essential.

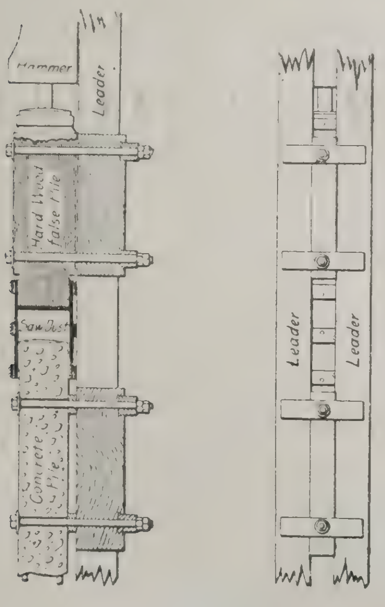

FIG. 11.—FALSE PILE AND DRIVING CAP EMPLOYED AT CHANTENEY-SUR-LOIRE,

Fig. 1 shows the cast steel helmet devised and employed by M. Hennebique for driving his piles. It fits over the neck of the pile loosely, and the annular opening at its lower edge is covered with clay and tow, and the hollow space above is filled through a hole in the top with sand, or preferably with sawdust. A separate cap is required for each size of pile. In driving most of the Hennebique piles at Southampton a timber dolly was also used in addition to the metal cap.

Fig. 11 shows a more complicated arrangement employed in driving the sheet piling at Chantenay-sur-Loire in France. Here the piles were cast with reinforced tops, which were desired to be shattered sufficiently in driving to expose the reinforcement. These allowed the top of the pile to be clamped loosely to the guides of the pile-driver as shown. A metal cap with a lower and upper socket was set upon the neck of the pile with a filling of sawdust over the top of the pile, and its upper end received a hard wood dolly clamped in the pile driver guides as shown.

In driving the triangular piles above referred to, a cap was used made of alternate layers of iron plate, wood, and lead. This cap was clamped at the head of the pile, and also served to guide it.

Another device used consists of a metal cap similar to that shown in Fig. 12, but having the socket on top, in which there is a piece of hard wood interposed between the pole and the dolly to take the direct blow of the hammer.

As regards driving by means of a water jet (the arrangement for which is usually as shown in Fig. 13), we may refer to the construction of the River Aisne bridge at Soissons, in France. Both the sheet piles and the bearing piles were of Hennebique construction. Some of the pier piles were 9.8ins. square, and 11.8ins. All the sheet piles were 5.9ins. by 13.8ins. in cross section. The material penetrated was sand mixed with a few pebbles. An attempt was made at first to drive some of the 9.8in. square piles with ram drivers, using a driving cap and dolly, as shown in Fig. 243, p. 347, Buel, with a 1,320lb. hammer. The first pile driven reached a depth of 8.2ft., but its head was completely shattered for about 1.97ft. The second pile had its head shattered at the first blow, and by the time it had reached a depth of 3.28ft. the metal was bare for a length of 2.29ft. Owing to this poor success with driving by means of a ram, the engineer substituted a water-jet apparatus. The engineer in charge of the work attributed the failure of the ram driving to the piles being of insufficient age, being only 1½ months old, and also to the fact that they were moulded on their sides instead of vertically. In driving the remaining piles use was made of a hand pump, which, however, gave a pressure too low to loosen the material sufficiently. The mode of procedure was to operate the pump until the earth under the point of the pile was loosened, and then to give the pile a few light blows with a hammer to set it into the loosened soil. This process was repeated until the piles had penetrated a distance of from 8.2ft. to 9.8ft. Six days were required to drive 18 piles. In placing the piles in the two piers, power pumps were substituted. To guide the piles a timber frame was used, as shown in Fig. 14. A panel of eight or ten piles was erected in the guides and driven, and then another panel, and so on, these piles being employed in a coffer dam.

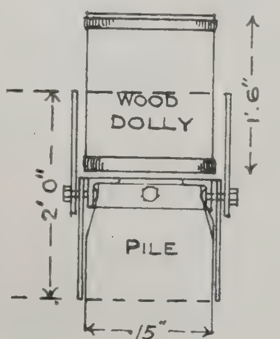

FIG. 12.—COIGNET CAP FOR DRIVING

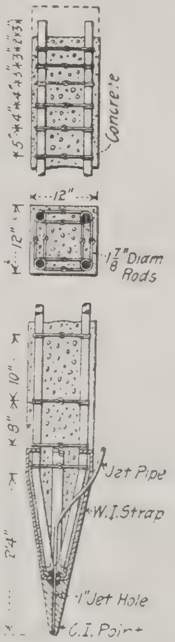

FIG. 13.—ARRANGEMENT FOR DRIVING BY MEANS OF A WATER JET.

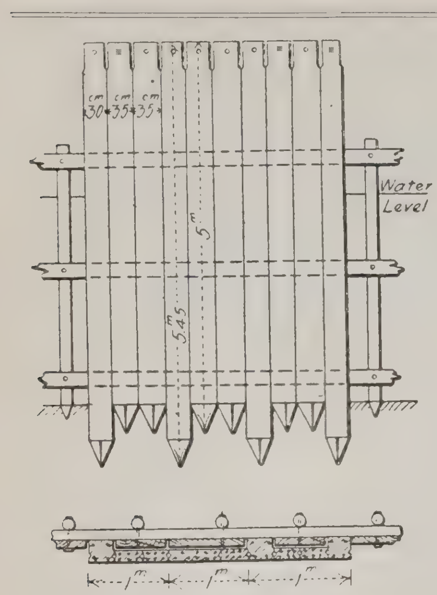

FIG. 14.—TIMBER FRAME FOR GUIDING PILES.

Steam pumps supplied the jet which was delivered against the soil by an armoured hose, terminating in a iron tube 1.38ins. in diameter, and 22.96ft. long. This tube or nozzle was manipulated by a workman, so as to deliver a jet underneath the point of one pile at a time. The pile was forced down by a lever over its head. With a gang of six men a panel of five or six piles could be sunk 3.82ft. in one hour. In one instance 45 piles were driven in a day's work.

(To be continued.)

In Parliament.

By our Gallery Representative.

Tenders for Egyptian Railway Buildings.

In the House of Commons last week, Mr. Staveley-Hill asked the Secretary of State for Foreign Affairs whether his attention had been called to the complaint of English manufacturers that samples supplied with the tenders for the supply of ironmongery for buildings and furniture for the Egyptian State railways were of French manufacture and consequently offered difficulties for English manufacturers to work to; and whether he could suggest to the Egyptian Government a method by which English manufacturers should no longer be under any disability in tendering.

Sir Edward Grey, in reply, said he had not heard of the complaint to which Mr. Staveley-Hill alluded, but if he could give him further information he would inquire into the matter.

The Studio on Primrose Hill.

Sir William Collins asked the First Commissioner of Works if he could now name a date when the work proceeding in the studio of Mr. Brock, on Primrose Hill, would be completed and the area railed off from the hill be restored to the use of the public.

Mr. Harcourt said he regretted that he was not yet able to fix a final date for the completion of Mr. Brock's work.

Scottish Museum Expenditure.

Mr. Munro Ferguson called the attention of the Lord Advocate to the published annual reports of the Director of the Scottish Museum and to a recent official return from which it appears that during the period of 10 years ended March 31st, 1908, the sum of only £1,274 was expended in Scotland on the purchase of sites, erection of buildings, and extension of existing buildings, while in the same period £550,597 was expended for similar purposes on the London museums. He asked whether any steps were being taken to provide the increase of accommodation required by the Royal Scottish Museum.

The Lord Advocate promised that the question would be considered when the estimates for 1910-11 were being settled.

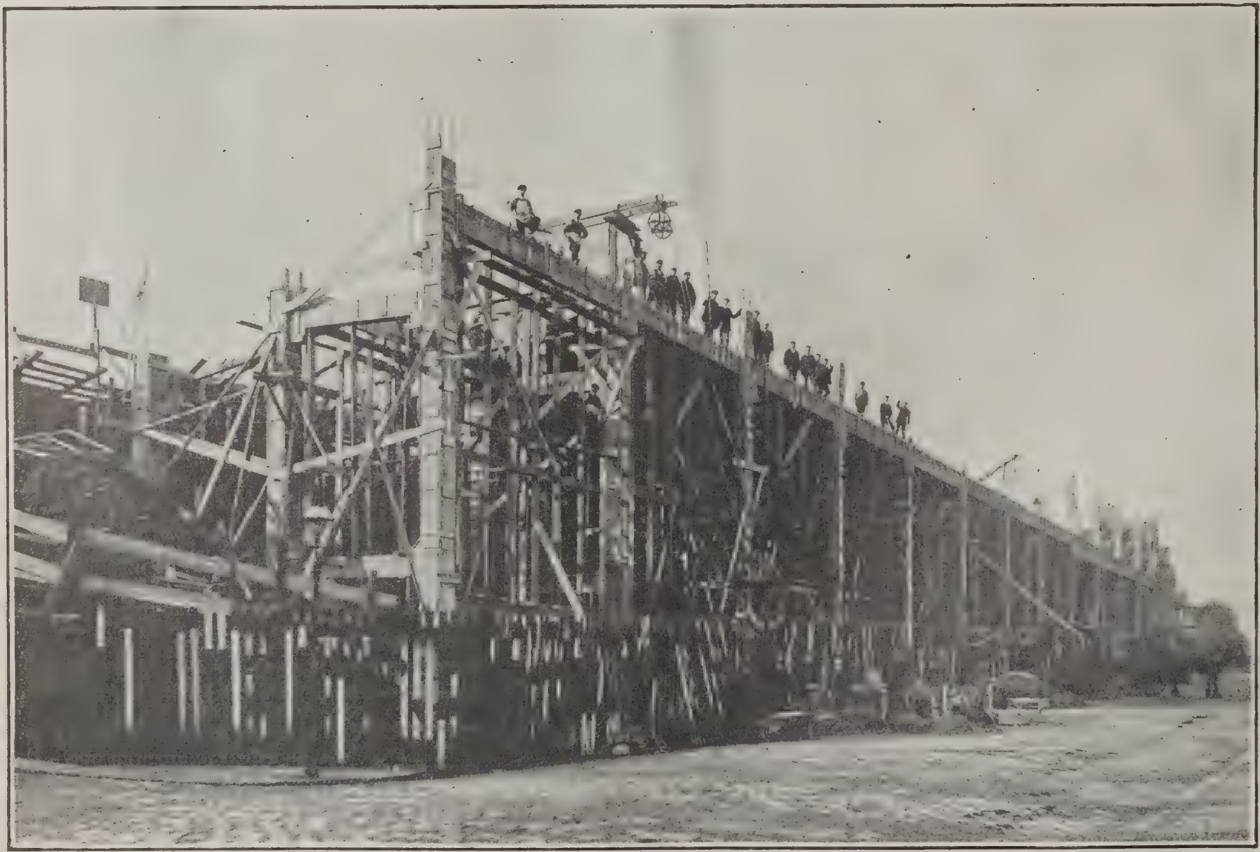
Duke of York's School.

Mr. Horniman asked the Secretary to the Treasury whether, in view of the recent removal of the Duke of York's School from Chelsea, the Treasury had considered the question of the sale of the freehold of the site; whether the advantage of retaining the said freehold, while letting the same on a building lease, had been duly considered, so that the unearned increment thereon might continue to revert to the Treasury; and whether any conditions as to the laying out of the site and the preservation of a portion as a garden for the public use were proposed to be annexed to such lease or deed of sale.

Mr. Hobhouse, in a printed reply, stated that the matter was under consideration.

Fair Wages Clause and Post Office Contracts.

Mr. Sydney Buxton, Postmaster-General, informed Mr. James O'Connor that in all contracts into which he entered for the alteration or repair of post office premises the fair wage clause was inserted. Careful investigation was made into any alleged breach of the clause.



BRADFORD FOOTBALL STAND.

This structure, one of the many instances in which reinforced concrete takes precedence by reason of its durability and the absence of expense in painting, etc., has been constructed with Kahn Reinforcement.

PRACTICAL CONCRETING.

(*Continued from p. 75, No. 755.*)

Tamping.

There is much difference of opinion, especially amongst engineers, as to the consistency of concrete. Some advocate the use of abundant water, others but just enough to obtain cohesion. When the concrete can be tamped or compressed, undoubtedly a moderate amount only should be employed; but if neither is practicable, except to a very limited extent—as for walls and floors—a more sloppy or pulpy state is essential, otherwise the concrete cannot be rendered homogeneous by reason of its dryness and stickiness, and consequent inaptitude of its particles to fill every crevice and interstice of the mass.

Setting.

Experiments made by the United States Government officials proved that "sloppy" concrete became much harder eventually than when only just water enough was added to create adhesion, but it took longer to acquire hardness. An advantage of well-saturated concrete is that it does not require so much tamping or beating, and in some cases none at all.

Chemical Action.

It is a peculiarity of Portland cement that it will not readily take up more water than is necessary for mixing, either with sand for mortar or with an aggregate for concrete, and if an excess is added the cement will part with it if opportunity offers. This is a curious property of cement; if it applies to lime it prevails in a much less degree, but there is no mistaking it in cement; if we could see the bottom of concrete after it had been trodden or rammed for foundations, we should find clear water, and on the top a sheet of writing paper could be saturated therewith and not soiled; in a short space of time the effluent water disperses itself in the minute cavities of the concrete. No positive harm arises from this effluent water that is known of, as its dispersal is gradual and gentle, and the cement having acquired an initial set is not disturbed thereby, but it plainly indicates that, although sufficient water is needed an excess is unnecessary. Perhaps more care is essential in this respect when the artificial foundations rest on a bed of clay or other non-absorbent material. If an unreasonable amount of water is used, the effluent water, instead of dispersing or throwing itself off, is in sufficient force to take with it a portion of the cement, and a serious weakening of the material ensues. In the case of concrete foundations this depletion results in pure cement being carried to the bottom thereof, and in walls or floors, wherever it may most readily find means of escape. If tricklings of cement are seen on the supporting boards of floors, or the encasing panels of concrete walls, it is direct evidence that too much water has been employed.

Depositing.

Prior to depositing, if the work is to be in trenches, the clerk of works is bound to see that the excavations are of the correct width and depth, and that a sufficiently good and level bottom is obtained, and that the trenches are free from water, mud, etc. If the trenches have been got out too wide, the extra width must be made up with concrete, and in no case must the proper width be kept by boarding, to be taken away as the concreting proceeds, nor must the void be filled with returned earth. If the concrete is to be deposited inside moulds, sheeting, etc., these must be inspected to see that no shavings, dirt, dust, or blocks of wood, etc., have been left in the same, which would occupy space that should be filled with concrete.

Experience has shown that no advantage is obtained by tipping concrete from a height to the level it is to occupy; at one time it was thought to consolidate the concrete mass.

The following further points are of importance in the uses of cement for concrete.

Cement Setting Properties.

The manufacturer has it in his power to make either quick-setting or slow-setting cement.

Slow-setting cement is that which sets after two or more hours, and is preferable to quick-setting cement for general work. Only for special purposes can a quick-setting cement be used advantageously.

In all cases the contractor should notify the manufacturer whether quick or slow-setting cement is required. This will obviate many unjustifiable complaints. But, first of all, it must be understood perfectly that the setting time asked for is actually required for the class of work to be carried out—he should not, for instance, order a quick-setting cement for grouting, and a slow-setting cement for pipe jointing!

Portland cement is of all cements the least sensitive to changes of temperature. Only during the process of setting can any injurious effect take place, and frost is then especially dangerous if the mortar is too wet.

In operations under water a quick-setting cement is preferable. In plaster work, cornices, etc., and when working in cold weather a cement should be used that is not too slow setting. In all other cases it is most advantageous to use a slow-setting cement.

Setting and Temperature.

Concrete sets more rapidly in hot water than in cold, and in the sun than in the shade. This is partly owing to the temperature of the water employed for mixing. It is unwise to attempt to make concrete with the thermometer below freezing point; in fact, some engineers state that concrete should not be made or employed when the temperature of the air on the ground is below 40 degrees or above 90 degrees, and that the temperature of water used for mixing concrete should not be less than 40 degrees. Very hot weather is unsuitable for concrete work, especially if it is exposed to the sun. The more asorbent and the drier the aggregate, the sooner the initial set commences.

Tamping.

The amount of force required in the tamping and the number and duration of the blows must depend on the size of the blocks to be made, and on the coarseness of the product. If insufficient force is used the material will not be as homogeneous as it should be, and internal strains will be produced which may prove serious later. Particular care should be taken that at first blocks of excessive depth are not attempted. These are exceedingly difficult to tamp effectively, and are a constant source of annoyance. The concrete maker, in his ignorance, lays most of the blame on the cement, changes his brand frequently and makes himself generally objectionable, whereas a little more friendly and tactful sympathy on the part of the cement maker to whom complaint is made would ensure the removal of this impression. Such detail as the tamping of concrete in constructional work is often thought to be beneath the notice of the average cement consumer, but he will find it of advantage to pay special attention to the point.

Cement Floors.

To construct durable floors of concrete the subsoil should be prepared in the following manner:—

For cement floors in the open, with great variations in the soil, after excavating to the necessary depth, a layer of coarse gravel or of ashes at least 18 inches deep should be made, levelled and rammed down. This serves to isolate the concrete and to draw off any moisture.

In places under cover, with a dry subsoil, it is sufficient to level and ram the subsoil down thoroughly.

The flooring should be in two layers, one of concrete, from 6 to 10 inches in thickness, which must be thoroughly tamped down, and an upper one made of a rich mortar about 1½ inches thick.

The mixture of the concrete for the bottom course may be made in one part cement, three parts sand, and five parts broken stone.

The upper layer is applied before the concrete has set, and is prepared by mixing one part of Portland cement with one part of sand. Before applying the top layer the concrete should be cleaned and roughened.

When the work is finished the surface should be carefully covered over and kept moist. In this way hair cracks may be obviated. If this necessary precaution is not taken cracks may occur, especially in the case of very large surfaces.

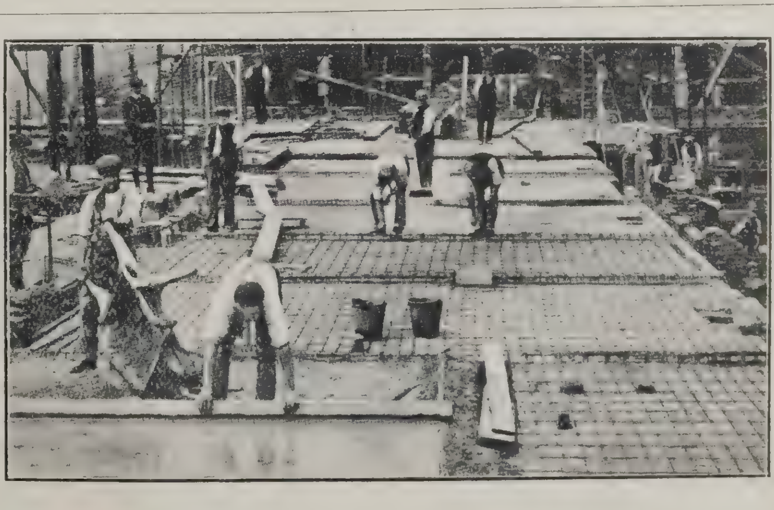
General.

To obtain the best results great care must be taken in the preparation of the mortar. Pure Portland cement may be used as mortar where the work remains permanently under water or in wet ground, or in enclosed spaces. Otherwise Portland cement must be mixed with a greater or less quantity of sand.

The quality of the sand, gravel and stone, has a great influence upon the hardness and strength of the work when finished.

Sand used must be coarse, clean, sharp and free from loam. The quantity of sand mixed with the cement is determined by the character of the work to be undertaken. One or two parts (by volume) of sand to one part (by volume) of cement is only employed when extrordinary hardness, great durability and water-tightness are desired. Three parts of sand to one part of cement is used for ordinary masonry.

The broken stone employed in concrete must not be inferior in point of hardness to the cement mortar used, therefore it is preferable to use granite, gravel, or hard limestone. The use of sandstone, brick-bats, and generally any porous stone should be avoided if the concrete is to be exposed to the influence of frost.



REINFORCED CONCRETE FLOOR AT THE WOMEN'S HOSTEL, BIRMINGHAM.

MAKING CONCRETE BLOCKS FOR THE NEW SOUTHAMPTON DOCK. *Photo: Topical.*

The view shows the extensive plant laid down for the manufacture of concrete blocks by the Contractors, Topham, Jones and Railton.

The pieces of broken stone or gravel should not exceed the size of a hen's egg.

In the case of good Portland cement, competent engineers suggest that the composition of concrete should consist of one part of cement, three parts of sand, with as much as five parts of broken stone.

The use to which it is proposed to put concrete should determine the quantity of sand and stone to be added to the cement.

Mix the sand and cement thoroughly before adding stone.

Add the stone to the mixture of sand and cement, and thoroughly mix these materials before water is added. Then add the necessary quantity of water and mix the whole mass again very thoroughly. Use immediately.

Clean water should be used in making mortar.

Do not change the proportions of cement, sand, and stone after the proper quantity of each has been decided upon, if a satisfactory piece of work is desired.

Great importance attaches to the careful tamping of concrete until water appears upon the surface, as it is only well tamped concrete that possesses great density and hardness.

The addition of water to the mortar is to be increased or diminished according to the requirements of the cement.

General practice requires the cement to be mixed with as little water as possible, and the mortar to be brought to the proper consistency by a prolonged and vigorous mixing.

Cement mortar is made by first spreading out the sand that has been measured, then the necessary amount of cement is spread over it and the mass stirred together until a uniform mixture is obtained; finally the necessary quantity of water is added and the mortar thoroughly worked.

It is important that the stone and brick, prior to being used, should be thoroughly wet.

Mortar that has set should be thrown away and on no account be retempered for use. It possesses no hardening properties and is therefore worthless.

The Special Commission on Concrete Aggregates, appointed by the British Fire Prevention Committee, have now prepared a provisional specification for concrete aggregates, which it would be well for all concretors to bear in mind, viz.:—

Artificial Materials for Aggregates.

1. Coke Breeze.—Coke breeze for use as a concrete aggregate shall be entirely coke taken from the gas retort, coke oven, or special furnace. It shall be absolutely free from clinker, coal, and all substances that will not float in water, and from any admixture of material taken from the retort furnace or water-pan below it, and from cinder, ash, or other admixture. The proportion of sulphur in coke breeze shall not be more than.........per cent.

Note.—It was decided that the determination of the allowable amount of sulphur should be the subject of future consideration.

2. Clinker.—Clinker for use as a concrete aggregate shall be the thoroughly burnt and hard waste product of furnaces, free from dust, shale, or free lime, and not having more than.........per cent. of sulphur.

Note.—Pan breeze is included in this definition.

Note.—In this case, as in that of coke breeze, it was decided that the determination of the allowable amount of sulphur should be the subject of further consideration.

3. Blast Furnace Slag.—Blast furnace slag for use as a concrete aggregate to be obtained and selected from pig iron smelting furnaces (to the exclusion of basic slag), to be of porous quality, to be washed to remove dust and sulphur, to be without free lime, and not to contain more than......... per cent. of sulphur.

Note.—In this case also it was decided that the allowable amount of sulphur should be the subject of further consideration.

4. Broken Brick.—Broken brick for use as a concrete aggregate shall be from well-burnt and perfectly sound and hard clay bricks, such as London stock bricks, or bricks of equal quality, and shall be of the size specified and be free from old mortar, and from dust or particles that will pass through a sieve of ⅛-in. mesh.

5. (a) Gault Clay Burnt.—Burnt gault clay for use as a concrete aggregate shall be free from free lime and sulphur and from unburnt particles, and shall be thoroughly hard, so that pieces soaked in water for ....hours shall not disintegrate.

Note.—It was decided that the Tests Sub-Committee should be asked to determine the length of time to be inserted in the clause.

5. (b) Ordinary Burnt Clay Ballast.—Ordinary burnt clay ballast for use as a concrete aggregate shall be free from free lime and sulphur and from unburnt particles, and shall be thoroughly hard, so that pieces soaked in water for.........hours shall not disintegrate.

Note.—It was decided that the Tests Sub-Committee should be asked to determine the length of time to be inserted in the clause.

5. (c) Broken Terra-cotta (1) Porous.—Broken porous terra-cotta for use as a concrete aggregate shall be (a) from clean and well-burnt earthenware, unglazed, which has been mixed before firing with some combustible material such as sawdust, so that

after firing it is of a porous or cellular texture, or (b) from clean and well-burnt unglazed earthenware which is capable of absorbing at least.........per cent. of its own weight of water. (2) Dense.—Broken dense terra-cotta for use as a concrete aggregate shall be from clean and well-burnt earthen or stone ware, unglazed, and shall be incapable of absorbing more than.........per cent. of its own weight of water.

Note.—It was decided that the Tests Sub-Committee should be asked to determine the percentages to be inserted in these clauses.

Natural Materials for Aggregates.

6. Natural Ballast (Gravel).—Natural ballast for use as a concrete aggregate shall be gravel from river beds, sea coasts or glacial deposits, washed, if necessary, to remove dirt, loam, earthy or saline matter, clay, and other foreign substances.

7. Volcanic Rocks.—All rock of volcanic origin for use as a concrete aggregate shall be entirely free from decomposed parts and must show no signs of expansion, disintegration, or dissolution after having been immersed in water for 72 hours. Rocks of this nature may be divided into the following classes:—(a) Basalts, traps, dense lavas, etc., weighing not less than.........lbs. per cubic foot. These shall be dense, thoroughly vitrified, not scoriaceous, show a clean fracture when broken, be homogeneous and free from marked cellular structure. (b) Lavas and rocks of similar character weighing not less than.........lbs. per cubic foot. These shall be hard and free from all soft or organic matter, but they will not be so hard, and will be more cellular than those of section (a). (c) Pumice weighing not more than ....lbs. per cubic foot. It shall be hard, free from all organic matter, soft dust or impurity, and show a bright silky structure when broken.

Note.—It was decided that the Tests Sub-Committee should be asked to determine the weights to be inserted in these clauses.

8. Granite.—Granite for use as a concrete aggregate shall be obtained from.........(here insert name of quarry), and shall be reduced to the specified dimensions by crushing or breaking, and shall be close, hard, and of even texture; free from large crystals of felspar, dirt, argillaceous or organic materials, all decomposed particles, and from dust that will pass through a 1-16-inch mesh.

9. Sandstones, Limestones, Quartzites, and Rocks of Similar Character.—Rocks of these characters for use as concrete aggregates shall be dense, uniform, and homogeneous in structure and composition. They shall have small, even grains and crystalline texture.* Fractures shall be clean and free from large flaws. The weight of the material shall not be less than 130 lbs. per cubic foot, nor its crushing strength less than 200 tons per square foot, and it shall not absorb more water than 8 per cent. of its weight after immersion for 24 hours. The aggregate after preparation shall be free from all dirt, decomposed rock, argillaceous and organic material.

---

*This is not intended to exclude Oolites otherwise suitable.

REINFORCED CONCRETE FACTORY AT HARROW.

An extensive reinforced concrete factory, which has just been completed at Harrow for the Kodak Company is here illustrated. The building, which measures 337ft. without a cross wall by 39ft. 7½in. wide, consists of two floors and roof in one part, and in the other portion three floors and roof. The first floor is supported by a row of columns which run the full height of the building, supporting the intermediate floors and roof, the section of these columns at ground floor being 14in. by 14in. reduced to 10in. by 10in. on upper floors.

The first floor girders run from wall to wall, being supported in the centre by the columns, the clear spans being 19ft. 9in., section of main girder 21in. by 12in. Between these run intermediate beams, 14in. by 9in., forming panels 16ft. by 6ft. 7in., the 4in. floor being supported on these beams.

The main roof forming covering to first floor is of rather unusual design, as, owing to the prohibition of projecting beams, it is constructed in a clear span of 19ft. 9in., being supported on one side by a single girder running the full length of the building between the columns, and by the wall on the other.

This floor, which is 12in. thick, is constructed with tiles to section as shown on detail, 12in. by 12in. by 10in., with a 4in. space between the tiles, which is filled in with concrete and reinforcing rods, so forming small concrete beams at 16in. centres, the tiles being covered with a 2in. layer of concrete, which is weathered with vulcanite. The necessary falls were formed in the centering, so doing away with the necessity of thickening up the concrete topping. The upper roofs were constructed in a similar manner. The concrete throughout was composed of crushed ballast, washed sand, and cement gauged in the proportions of 1 cement, 1⅔ sand, to 3⅓ crushed stone.

Messrs. D. G. Somerville, the contractors for this work, which they are constructing on the Kahn system, report that they have at the present time an exceptionally large number of important contracts in hand, and that they are just starting on what will probably be one of the largest reinforced concrete buildings in the South of England, namely, new printing works at Blackfriars, and it is anticipated this will take at least a year to complete; and as there will not be a brick or steel joist in the building, this should form a notable addition to the increasing number of complete reinforced concrete buildings in this country.

REINFORCED CONCRETE FACTORY, HARROW.
The building measures 337 ft. long by 39 ft. 7½ in. wide.

REINFORCED CONCRETE FACTORY, HARROW
The floor girders run from wall to wall, the section of the main girder being 21 in. by 12 in., the clear spans being 19 ft. 9 ins.

Federation News.

MANCHESTER, SALFORD, AND DISTRICT ASSOCIATION.

Secretary: J. Tomlison.

Since the last report two new members have been elected into the association. The joiners' branch, after two years' negotiations with the operatives, have now arrived at a settlement regarding their working rules, with the exception of the district within which the same are to apply. As this is likely to take some considerable time to define, owing to the Manchester district being so closely surrounded by other federated districts who will have to be consulted, the amended rules have been issued as far as they have been agreed to.

The plasterers' branch have also completed their negotiations with the operative plasterers and labourers for amended working conditions, the chief amendment being the abolition of the old walking time rule, which has been superseded by payment of expenses in and out each day, the men to be on the job at starting time. This alteration has also been gained by the joiners and masons' branches, so that as far as the three trades are concerned walking time has become extinct. The masons' branch, after taking their dispute with the operatives before the whole of the boards provided under the national scheme, failed to attain any settlement, with the result that they at first declined to accept arbitration as recommended by the National Board, and after receiving the support of the association and of the Lancashire and Cheshire Federation they decided to enforce their notice for a reduction in wages and amended working hours. The men struck against this notice on July 10th, and after being out on strike about two days the employers, acting on the intervention of the Board of Trade, who had interested themselves in the matter, decided to place the same before a Board of Trade arbitrator, and the men immediately returned to work. Since then a joint meeting has been held with the operatives, and all rules, with the exception of the wages and working hours, were mutually agreed upon. The arbitrator appointed by the Board of Trade (A. A. Hudson, Esq.) heard the case in Manchester on Monday, the 9th inst., and he awards a reduction in wages of ½d. per hour with extended working hours, practically the old conditions prior to their being amended by the local Conciliation Board twelve months ago by a mistaken vote. He also decided that the amended conditions shall take effect as from Saturday, the 14th inst., and remain in force at least twelve months from the date of his award, during which time no notice for alteration shall be given by either side. This means that the employers of masons have carried every point which they set out to recover, as contained in their notice to the operatives. The General Committee of the association have under consideration the question of "municipal trading," and the matter is being discussed with a view to approaching both the Manchester and Salford Corporations thereon.

THE BELGIAN MASTER BUILDERS

Dinner given by the London Master Builders' Association.

On Thursday evening last, August 12th, the London Master Builders' Association entertained to dinner at St. Ermin's Hotel, Westminster, a number of Belgian master builders, whose tour in England, which extended over seven days, ended last Saturday. Among those present at the entertainment were the following:—Mr. F. G. Rice, president L.M.B.A., in the chair; Mr. D. S. Rice, Mrs. Rice, Mr. Arthur Brown, Mr. E. J. Brown, Mrs. Brown, Mr. A. G. White, secretary N.F.B.T.E., of G.B. and I.; Mr. W. F. Wallis, Mrs. Wallis, Mr. Fredk. Higgs, Mr. G. Bird Godson, Mr. James S. Holliday, Mr. Leonard Horner, Mr. H. W. Horner, Mr. Joseph Randall, Mr. A. W. Turnbull, Mr. H. Knight, Mr. C. Wall, Messrs. J. Chessum and Sons, Mr. Albert Monk, Mr. J. W. Jerram, Mrs. Jerram, Mr. E. A. Hough, Mr. G. H. Parker. Among the Belgian guests were Mr. Vandewren, V.P., of the Brussels Association; Mr. Hesbain, president of the Antwerp Association, and V.P. of the Belgian Federation; and Mr. Van Autryve, president of the Ghent Association.

At the conclusion of the dinner, the chairman (Mr. F. G. Rice) addressed the gathering in French. As, he said, their guests were doubtless anxious to make the best of their brief visit, the toast list would be short. He regretted that the expected friends from Sheffield had been unable to attend the dinner, but their absence was unavoidable. He had received a telegram conveying their regrets and wishing the Belgian visitors an excellent and enjoyable time.

The toasts of "The King" and of "His Majesty King Leopold" were enthusiastically accorded with musical honours.

Mr. Hesbain, speaking in English, said the President had addressed them in the French language, which was one of their two national languages, and he would do his best to reciprocate the compliment by addressing them in English. They must excuse him if his attempt proved a failure, as he doubted his ability to speak so successfully in English as the President had done in French. In the name of the National Federation of Belgian Builders, of which he had the honour to be vice-president, he thanked their host and his friends for the hearty way in which they had been received, and for the hospitality which had been bestowed upon them since the moment of their arrival. It was extremely kind to give them such a reception, and to entertain them to such a princely dinner. He was glad that the health of their King had been drunk in a manner not only of loyal subjects, but of builders. Their sovereign was known as the "King of Builders." To be in sympathy with the great English nation was surely good, and he believed could only tend to promote that friendliness which they all desired. Last year, when they had received the Sheffield builders at Brussels, a mutual friendliness had arisen, and it was directly owing to that visit that they were here now. He could not thank them enough for the kind reception, but he hoped that their English friends would come in great numbers to the International Exhibition to be held at Brussels next year, when they hoped to pay back the kindness they had received.

The chairman, speaking in French, then proposed the toast of "Our Guests." He said: "Ladies and gentlemen,—Here we have a complete picture. Round this table are gathered the builders of two different countries, for, although our lands are separated by the North Sea, our wishes and our aspirations are exactly the same. The visit you have honoured us with has caused us great pleasure, and I hope it has been the same for you, and that you have enjoyed our company. I am sorry that your visit has occurred during the holiday season, and that owing to this dining room not being large enough to hold us all only a small reception committee of our association could be here to meet you. I hope I shall visit Belgium next year for the purpose of seeing the International Exhibition of Brussels, as doubtless many of my countrymen will do, which you are now so busily preparing for the enjoyment and edification of your visitors, and which I feel sure will be the great success it deserves to be. Some of your countrymen visited this country two months ago and were successful in winning the Great Challenge Cup at Henley, and, although you do not return to your country bearing the laurels of victory, I hope you will take back with you many happy memories from England. I know that you have in Belgium a great number of buildings which are excellent examples of good design and construction, and which can truly be called works of art. I hope that your visit to England has not disappointed you, and that you have observed some of our buildings, both ancient and modern, worthy of your remark, and of which we, as Englishmen, are so justly proud. We are all united in the desire of beautifying our different countries with fine buildings, but here in England we have not so often the opportunity of doing so as we should wish, as the state of the building trade is now very depressed. I hope it is not the same in Belgium, and that you may always have in your own country plenty of work to occupy your time and abilities. We are glad to see the ladies amongst us, and I shall ask my friend Mr. Higgs to propose a toast to you.

I give you the toast "Our Guests," and success and prosperity, coupled with the name of Mr. Van Dyck, the worthy president of the Chambre Syndicale des Entrepreneurs de Travaux des Belges."

Mr. Vandewren, speaking in French, replied to the toast, and Mr. Arthur Brown afterwards summarised the remarks in English. Mr. Vandewren, he said, was pleased to be associated with the health that had been proposed. He would like to thank them for the way in which they had been received in London. He was most happy to think that their friends proposed to come to Brussels next year to see the great buildings and the objects of art. Let the members ever bear in mind the words, "One for all and all for one," and they would go forward hand in hand to success. He drank to the society and to the president. Mr. Van Autryve then addressed the meeting in Flemish, and Mr. Hofman (secretary of the Chambre Syndicale) translated his remarks into English. Mr. Van Autryve was glad to be able to voice his thanks for the generous way in which they had been received in England. Wherever they had gone they had been greeted in a most hearty and friendly manner. Mr. Fredk. Higgs, speaking in French, then proposed the toast, "The Ladies," which was received with obvious delight.

Mr. Hofman responded for the Belgian ladies in English, and said that, judging from the nice words that Mr. Higgs had spoken, he was unmarried. In the name of his fair countrywomen he heartily thanked Mr. Higgs for the toast. At the request of the President, Mr. E. J. Brown made a humorous valedictory speech in French, which was also punctuated by bursts of spontaneous mirth, which conveyed in no uncertain way the whole-hearted appreciation of the happy Belgians. With this the dinner concluded.

Trade and Craft.

Messrs. J. F. Phillips and Son, of 21, Old Queen Street, Westminster, S.W., Brighton and Liverpool, who are the licensees for the Cable system of heating, have now in hand the following installations, viz.: The French Hospital, Shaftesbury Avenue, W.; the Borough Hospital, Brighton; the Royal Alexandra Hospital for Sick Children; the Sussex Eye Hospital. The Cable system, owing to its independence of levels and avoidance of all underground ducts and channels, in addition to its other many advantages, renders it specially advantageous in hospitals, asylums, schools, and public buildings generally.

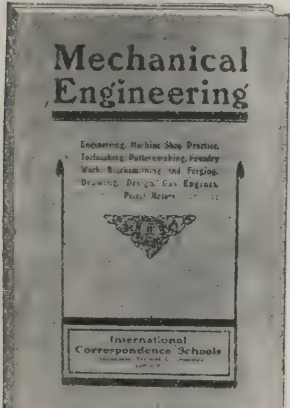
Insurance.

Free £500 Accident Insurance Coupons have this week been sent to the following: J. C. S. (Edinburgh), G. W. B. (Mansfield), C. B. (Reading), H. V. (Reading), G. W. W. (Newcastle), W. M. E. (Liverpool), E. F. H. (Newbury), H. B. (Plumstead), J. C. (Manchester), W. R. G. (Southgate), G. B. L. (Bournemouth), W. H. H. (Royston), J. G. T. (Abergavenny), L. S. (Huddersfield), F. M. (Reading), J. D. C. (Notting Hill), C. S. (Manchester), H. J. A. (Ashburton), L. H. (Holmfirth), G. H. D. (Birmingham).

Five Years Ago these Two Men Started Level

—one is still at his bench, toiling hard and long for a slender pittance—the other now occupies a high-grade position in his profession, enjoying high pay, congenial work, influence and power. What is the reason of the present difference in their fortunes? It is not that the successful man has more brains than his "stand-still" colleague of five years ago—**but he does know better how to use them.** In a word, he has **trained** his brains on practical remunerative lines, while the man still at the bench has not.

This instance is just typical of thousands we could cite in which men have devoted a few months to serious home study with the International Correspondence Schools, and, as a direct consequence, have secured a future of success and happiness, while their less ambitious colleagues have condemned themselves to a monotonous continuance of the old round of drudgery.



Mechanical Engineering
Engineering, Machine Shop Practice, Toolmaking, Patternmaking, Foundry Work, Blacksmithing and Forging, Drawing, Design, Gas Engines, Petrol Motors
International Correspondence Schools

Free books on subjects below.

What about Yourself Five Years from now?

You must be ambitious or you would not have read thus far. Determine then to realise your ambition—to rise out of the rut—by enrolling right away for a course of specialised training with the International Correspondence Schools. Spare time home study only is required. You make the fullest use of your leisure, wasting no time travelling to and from classes. You make every hour you give to study count in your career, for the I.C.S. course arranged for you will have the one and only aim of preparing you for the high grade position to which you aspire.

The evidence of the thousands of students who have benefited by our training during the past 17 years is conclusive on this point. This is how one of them puts it—

Aston, Birmingham.
"There is no doubt that yours is in reality 'the system that raises salaries,' that raises a man who doesn't mind work to the highest eminence in his trade."
(Signed) A. H. Du Rose.

Mark the Coupon below, or write us about any other career. Don't delay! Think of the significance to your future of your present choice and

TAKE THE WISE STEP TO-DAY

Caxton House, Westminster, London.

L. & C. HARDTMUTH'S
KOH-I-NOOR PENCIL

is the most economical Pencil made. It lasts six times as long as an ordinary pencil. But it is the velvety smoothness of the lead that is the great charm of the Koh-I-Noor. There is no other pencil that nearly approaches its quality. The lead of the Koh-I-Noor is specially prepared by a perfected process which gives it a firmness yet delicacy of touch that cannot be imitated. The Koh-I-Noor is made in seventeen degrees to suit all pencil purposes.

Koh-I-Noor Pencils are 4d. each, and 3s. 6d. per dozen, everywhere. Of Stationers, Artists' Colourmen, Photographic Dealers, &c. Booklet free from

L. & C. HARDTMUTH,
12, Golden Lane, London, E.C.

KOH-I-NOOR
TRACING CLOTH

Is a stout and substantial cloth possessing every advantage for the drawing room. Its surface is smooth and clear, free from blotches. Does not tear or break. Is transparent enough for the finest work. Erasures may be freely made without causing the ink to run. Is excellent for giving impressions by process

THE GREATEST SATISFACTION IN USING THIS SPECIALITY IS FOUND IN ALL DRAWING OFFICES.

Of Stationers, Artists' Colourmen, Photographic Dealers, &c.

L. & C. HARDTMUTH, 12, Golden Lane, London, E.C.

The Ideal Home Discovered. To see ourselves as others see us may be a medicine for the soul, but it is apt to have a nasty taste. An American contemporary, who has been comparing English domestic architecture with that of American country and suburban houses, has kindly done his best to sweeten the mixture. He remarks on "the ability and ingenuity of our English brothers" (we thank him for that word) "to secure pleasing textures in the surfaces of walls and roofs." He states further that "the picturesqueness, the amazing variety, the distinct individuality, shown in the materials used and in the manner of employing them, are sources of continual wonder and admiration to us." So far the comparison appears to be in our favour. But it is evident that, in the opinion of our critic (who, however, is much too polite to say it outright), the Americans transcend us in the vital affair of planning, their supremacy in this matter being much greater than ours in the other, so that it is not really a case of "honours divided." "It has often seemed to us," says our American brother, "that the majority of the English country houses were designed from the outside in. To us, the English plan seems entirely a secondary matter. If the English architect secures a picturesque mass and a harmonious combination of materials and textures, the battle is won—the arrangement of the interior may be "divided to suit the tenant's needs,' if possible. If the given mass cannot be so subdivided, the tenant's needs will suffer, not the exterior appearance of the building." Our critic thinks that a reason for the avoidance of direct connection between closely related portions of the interior is the Englishman's ingrained love of privacy. 'It is natural for us [the Americans] to try to express in the exterior of a house the disposition of the interior. If we recognise at a glance when approaching a house that the dining-room is on this corner and the living-room on that, we think the building meets one of the requisites of good architecture. Not so with the Englishman. He wants no one to know, from the outside, anything of the interior arrangement—that is a very personal matter with the owner. And if the visitor wanders hesitatingly through the crooked halls, coming now and again upon an unsuspected little library or lounging-room, never completely grasping the general lay-out, the Englishman has secured his ideal home." In all this there is sufficient truth to raise an indulgent smile on the face of the English architect, who, while well aware that it is one of the canons of design that the house should be built from the plan, is lucky if he has not been compelled in some instances to forgo the rigour of the game in deference to the whims and oddities of obstinate or aggressive clients. He takes leave, therefore, to felicitate his American brothers on their more tractable and more complacent constituency. It is an undoubted fact that whereas the English client is decidedly apt to prefer his own ideas to those of the architect, and is occasionally addicted to fatuous and intolerable meddlesomeness in matters that are too high for him, the American, on the other hand, is commonly shrewd enough to recognise his own limitations, and to refrain from undue interference with the expert for whose skilled advice he is paying substantial fees. This difference in national temperament no doubt exists; but it is, in each case, easy to exaggerate it, and this, we suspect, is what the American critic has done, in order to heighten his contrasts.

Hardships of Tendering. Loose estimating is no doubt, as Messrs. George H. Gibson and Horne Morton observed in the course of a paper on "The Design of Industrial Works," read before the Glasgow Technical College Scientific Society, very unfair to proprietors, as it may launch them on a sea of expenditure that is wider and deeper than they had been led to expect, and, indeed, may conceivably involve them in ruin. The authors are therefore justified in laying stress on the necessity for exceedingly careful ascertainment in estimating for large works. The authors deal mainly with engineering works—and, by the way, they advocate that a single authority should be responsible for the design of the buildings, the steel structure, the power plant, and the transmission system: thus virtually eliminating the architect in favour of the engineer—but obviously the principle is equally applicable to less specialised buildings; and it is equally clear that carelessness in tendering works both ways. It may tend to ruin the builder rather than the client, and, under the system generally in vogue, it is certainly the contractor who is most liable to suffer. Possibly it is the knowledge of this fact that renders corporations and other clients less scrupulous than they should be in accepting tenders that, as compared with those of the other competitors, are so exceedingly low as to suggest to common sense that there must be some error, and that the work cannot possibly be done for the money. The contractor, therefore, well knowing from observation if not from actual experience that, in the event of miscalculation or other mistake, his accepted tender will be saddled upon him without compassion or compunction, owes it to himself also to do his utmost to keep well within the margin of profit. The task is not easy. Since, even under the most favourable conditions, clerks are fallible, and an estimate is at best of the speculative character that its very name implies, it is not at all wonderful that, when the estimators are compelled to race against time, very serious errors occasionally arise. Instances innumerable could be cited of the clerical staff being kept up all night, and for several nights in succession, getting out estimates of which ridiculously short notice had been given. It has often struck us that the acceptance of the lowest tender is a crude and barbarous way of deciding such competitions. On the face of it, there is something bordering on absurdity in the assumption that the lowest bid will secure the best bargain. It would perhaps be better for all concerned if it were the practice to accept, not the lowest tender, but that which approximated most closely to the mean of all the tenders received. Anyhow, we must again protest against contractors being harassed into error and then pinned down to it in the merciless fashion with which we have become only too familiar. The law on the subject seems to be badly in need of revision.

"Light" Humour. Even a Consistory Court is not exempt from the occasional intrusion of light comedy, or of the delicately ironical humour which is commonly called Gilbertian. Mr. Chancellor North, giving judgment in the Consistory Court for the Norwich Diocese, could not —and perhaps he would not if he could— suppress this latter exhilarating element. The matter before him was quite simple. Application was made for a faculty to remove from Kilverstone Church a stained-glass window and substitute cathedral glass. The little church (it has seating for seventy persons) was on the estate of the late Mr. Vavasseur, who, being a gentleman of great wealth, had restored the church with great taste and regardless of expense. He had desired the change for which the faculty was sought. When Mr. Vavasseur died, application was made to amend the citation by the substitution of Mr. Vavasseur's successors. Then Chancellor North discovered that the Court was being asked for leave to do something which had been already done; the cathedral glass having been *in situ* for three months! This, of course, was very improper. But who was to blame? Not the architect. The Chancellor did not know whether it was the business of the architect to see that there was a faculty before any work was done to a church. The incumbent? The Chancellor did not think that the incumbent was at all to blame. Then it must have been Mr. Vavasseur who had given the orders for the work, and who was dead. "Mr. Vavasseur had exposed himself to be proceeded against by articles for an ecclesiastical offence; *but, as he was dead, he was out of the jurisdiction of the Court*"—surely a right Gilbertian expression, reminding us very pleasantly of the extra-judicial utterances of the "highly susceptible Chancellor" in "Iolanthe." The faculty, however, was refused on its merits, the Chancellor finding no force in the plea that the plain cathedral glass was necessary as giving more light; "and that left it open for proceedings to place matters *in statu quo*," which means, we suppose, that the cathedral glass must be removed and the stained glass put back. Chancellor North, dealing with the belatedness of the application, quoted with approval the comments of his predecessor, Chancellor Blofield, on a similar case: "The Court should, I think, be very careful in its investigations of cases in which confirmatory faculties are asked for. When important alterations in, or additions to, a church are contemplated, it is obvious that a faculty authorising them should be obtained before the work is begun. To carry out the work without authority, and then perhaps only to apply for a confirmatory faculty when compelled to do so, opens the door to abuse and should not be encouraged; and it should be remembered that to do work requiring a faculty without one, exposes the doer to be proceeded against by articles for an ecclesiastical offence." Yet similar inversions of order are not uncommon. It happens quite frequently that corporations borrow money or begin works before obtaining Parliamentary or Local Government Board sanction. In their case, the plea of urgency may serve their turn; but there is always considerable risk in proceeding in advance of powers; and the awkward position that has arisen at Norwich certainly shows the unwisdom of presumption.

The New Architectural Tour.

The linking-up of London's tramways, which is at length making a near approach to completion—one might almost say, to perfection—possesses much special significance for architects and builders. For one thing, it has relieved, almost too thoroughly, the congested areas which, but a few years ago, made certain districts of London a byword and a reproach. It has given to suburban building operations an exaggerated stimulus, with consequent reaction, the depressing effects of which are on all hands evident in the vast numbers of unoccupied houses tabulated in the return that has just been extorted from Mr. John Burns, who surely must require to summon up all his characteristic optimism in order to view with anything like equanimity these perhaps unanticipated effects of his own strenuously pursued cheap transit policy. Most of the ill-effects, however, can be only temporary; but these, unfortunately, cannot be held to include the miles upon miles of cheap and shoddy dwellings that have sprung up to meet the sudden demand created by the rapid extension of the electric tramway systems. It cannot be denied that, as a writer in the daily Press observes, "the advent of the tramway is rapidly causing the landscape to be blotted by staring new houses and unsightly heaps of bricks and mortar." These, however, are not the only kind of buildings that one can see from the top of the car. A ride of a few miles, in any direction, on 'bus or tram, affords hitherto unexampled opportunities for a rapid superficial survey of London's buildings, old and new. It is now possible to ride by car from Barnet (in Hertfordshire) where the King-maker was killed, to Purley, in Surrey, where Horne Tooke indulged in his linguistic "Diversions." This is a distance—from the Great North Road to the Brighton Road—of some five-and-twenty miles, and it is some of "the houses in between," rather than any of the occasional and scanty, but by no means unlovely, landscape effects, that render the journey worth while to the studious architect or builder. Other journeys, of at least equal interest, and of almost equal length, can be made between North London and Bexley Heath in Kent, or between Purley and Waltham Abbey, which was built by Harold the Saxon, and possibly enshrines his bones. The London County Council's excellent route-book, in which the places of interest in and around London that can be easily reached by tram are enumerated, and in numerous cases illustrated, will now need amplification; and, furnished with this and with Murray, the architectural student will be at no loss for specimens of periods and styles. The linking-up of the tramways should be a valuable factor in his education, providing him with means and opportunities that he will not, it is to be hoped, be so foolish as to despise because they are cheap and obvious. The architect who knows his London thoroughly has achieved not only a professional, but a liberal education.

Earthwork in England.

The discovery of indications of a Roman villa on land controlled by the Associated Portland Cement Manufacturers affords further indication that, lying, perhaps unsuspected, beneath our feet, there are probably enormous stores of interesting relics of the Roman occupation. Indeed, so numerous, of late years, have been the discoveries in this kind, that there is some danger of our becoming sated with them, and indifferent to the value and significance of the treasures that they yield Yet every fresh discovery sheds fresh light on the history and customs, and the artistic and constructive methods, of the wonderful people to whom we owe our introduction to the arts, sciences, and laws of civilisation, and of whose characteristics and institutions we are to some extent the heirs. It would be a great pity, therefore, if the frequency of such finds were to breed the apathy of repletion, or the contempt that proverbially comes of familiarity. Indeed, apathy in such matters is already sufficiently pronounced. Otherwise, the enthusiasts would not be compelled, as they have been in so many instances, to abandon, for want of the necessary public support, excavations that were yielding rich results. The public indifference was brought home rather forcibly the other day to the writer of this note, who, on visiting the Roman villa at Morton, near Brading, in the Isle of Wight, was somewhat scandalised to find that the work there, which has produced such splendid discoveries of pottery, of excellently preserved decorative pavements, of baths, hypocausts, wells, etc., has come to a standstill, although in all probability further excavations would continue to yield a rich reward; and the conditions at Brading are typical of many another baulked investigation. Surely such educative work should not be eternally left to private enterprise, but should be amply subsidised from the national exchequer. Scholarly and enthusiastic workers are not wanting; and, with the necessary funds at command, they would soon collect materials for a really authentic account of the architectural and building methods of the Roman invaders. The most recent discovery of early British remains is perhaps that which was announced last Monday as having been made at Pokesdown, Bournemouth, where, on a hitherto unexplored site, there has been discovered what is believed to be an early British village.

Foreign Factories—Made in England.

The Patents Act having now been in operation for a full twelvemonth, the curious in such matters are taking stock of its effects. These appear to be favourable to building in this country. A foreign manufacturer of an article for which he has obtained a patent in this country must manufacture it here, otherwise his patent may be revoked, so that anybody is free to take up the manufacture in Great Britain. In some instances the revocation of the patent makes no material difference, the patentee holding the field so dominantly as to defy rivalry; for the revocation of his patent rights does not prevent his importing the goods. In other instances, the patentees have found it advisable to take the steps necessary to preserve their patent rights; and it is here that the Act proves beneficial to the British builder. Already, it is stated, twenty-four foreign firms who have thought fit to comply with the requirements of the Act have spent nearly £200,000 on the erection of buildings here; and it is believed that for some years to come the amount will continue to increase, there being as many as 30,000 British patents held by foreigners. Of these, not one in a thousand are likely to build in this or any other country; but, nevertheless, the most pessimistic view of the probabilities affords ground for hope that the Act must result in substantial benefit to builders and landowners, who will perhaps be willing to allow Mr. Lloyd George this comparatively slight set-off against the heavy per contra account represented by his Finance Bill proposals, which, in their assumed general discouragement of building—and even of the making of bricks, if clay-getting is to be taxed—may, indeed, even operate against the building of factories for foreigners. But, when political animus is allowed to pervert the judgment, it is easy to exaggerate both the good and the evil effects of legislation.

LEOPOLD BRIDGE, LIÉGE. GENERAL VIEW.
This illustration of the Pont Léopold, or Pont des Arches, Liége, affords an idea of the general effect. Details of the statuary, coping, etc , are shown at the foot of the page.

THE BRIDGE BEAUTIFUL: AND OTHERWISE.*

By Robert Boyle, B.Sc.

At a moment when the bridging of the Thames may be said to be under revision, the following extracts from a paper on "The Design of Bridges with Reference to Æsthetic Treatment" seem to be peculiarly opportune.

The author contends that in bridge design there need be no sacrifice of practical accuracy, of mechanical precision in workmanship, of reasonable economy, to include the qualities of good proportion, true elegance and beauty, as inherent parts of the structural system. There should fundamentally be a delicate proportion of parts, and every detail should be so chosen, all decorations should so act, as to emphasise, relieve, contrast, or distinguish special and important points in the structural scheme.

Rather than misplace the decoration on a bridge, leave it to tell its own tale without any ornament whatever; but occasionally a slight moulding, a bold accentuation of the arch, a bold marking of the roadway, renders a structure beautiful which might be only useful in appearance. Perfect combination is the secret of beauty. Correct treatment will consist in the unforced combination and mutual supplementing of the elements of the beautiful with those of the good and the true.

The collaboration of engineers and architects will be necessary in all first-class work. It is not a question of sending an engineering design for architectural treatment, as there should, in general, be a constant interchange of opinion, a see-saw of the plans, till the question is argued out and agreement results.

The author realises that no amount of observation of rules will produce a work of art, and that no complete set of rules on æsthetic treatment is possible. The main points emphasised in his paper are thus summarised:—

1. Æsthetic requirements are best met by appropriateness of design, by fitness of the structure for its purpose, by static correctness. This involves the axiom that any violation of engineering principles is also a violation of good taste.
2. The structure should be clear to the perception of the intelligent beholder, and create in him a feeling of satisfaction.
3. All beauty should be more inherent than extraneous.
4. The engineer should aim primarily and fundamentally at beauty of economy and material, beauty of workmanship, beauty of accomplishment, whether traditional architecture be considered or not.
5. The study of nature is the basis of all art.
6. Critics of engineering work are not yet educated up to a due appreciation of structural steel work and what it involves.
7. The main features in any design should be accentuated.
8. There must be no deceit, no suggestion of anything being what it is not: there must above all be truth.

Towards the close of the paper the author described some noteworthy existing bridges, classifying them according to type.

Type I.—Suspension Bridges.

No class of bridge lends itself more to artistic outline and graceful appearance. The outline is almost entirely in the hands of nature, and the curve of the chain is the most suitable for the function of the structure. The form is not radically altered by the subsequent addition of the weight of the platform. A bridge with a horizontal stiffening girder, sometimes assisted by sloping ties from the tops of the towers, is perhaps more useful and more economical, but is less flexible and less beautiful than when no attempt is made to control the flexibility of the chain. The most pleasing designs are those with two supporting towers. Designs with practically straight anchor chains are less graceful, less æsthetic than those with the approach spans supported by land chains with a curve similar to that of the chains in the central span.

Tower Bridge.

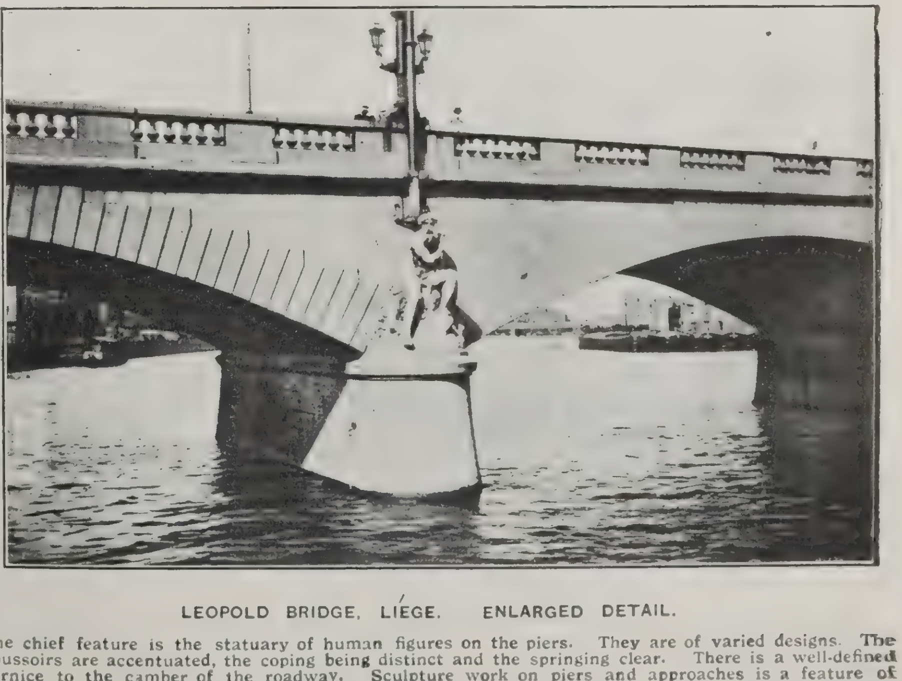
Because of the proximity to the Tower of London, it was originally stipulated that a castellated fortification at the north abutment should be part of the scheme. Such a principle is obviously objectionable. The four stone towers simply serve to enclose or hide four pairs of steel towers, which carry the loads from the suspension cables. The towers are standing in the air on a steel girder. It is all an attempt to make a thing look like what it is not. The heavy chains attached to the ends of the two high-level girders within the towers appear to be supported by the stonework, which they would pull down.

Menai Suspension Bridge.

The bridge is well suited to its surroundings, and is graceful in its details and proportions. If there be any fault, it is that the land arches appear to be redundant, and that the structure would have been more elegant, more proportionate, more a true suspension, if they had been absent and the bridge constructed like the Clifton suspension. A certain amount of stiffness, lateral rigidity, and aid in erection would, however, be given by the arches, and this is apparent to the observer.

Type II.—Arche.

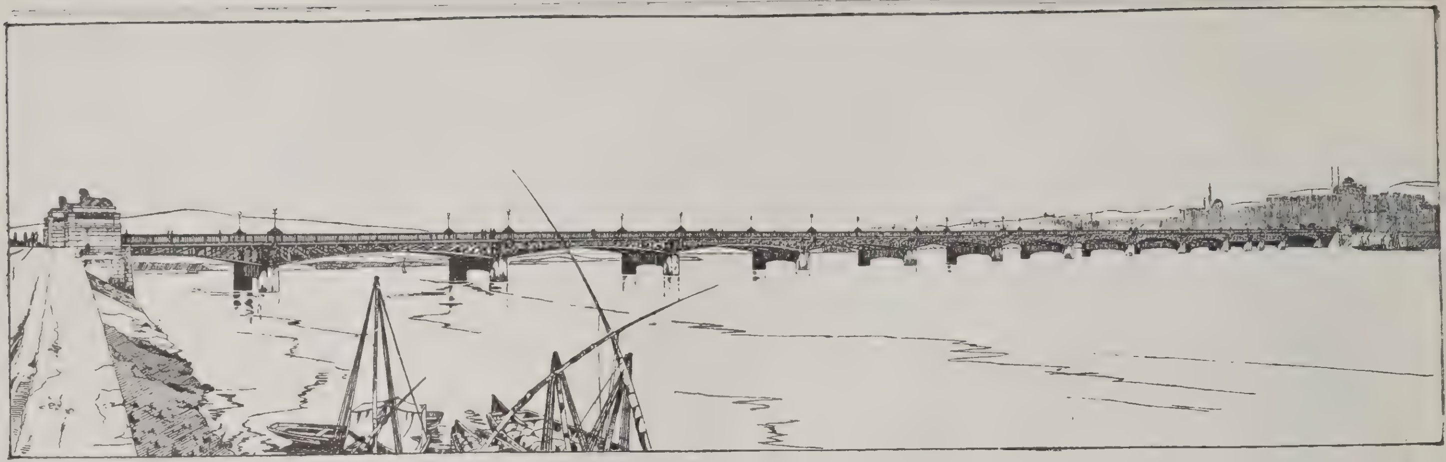
Masonry arches were built by the Romans, and, up to the end of the 18th century, masonry and timber were the only materials used. The first cast-iron arch was 100ft. span, and was built across the Severn at Coalbrookdale in 1779. Since then a remarkable development has taken place, steel being used for all the largest spans. Reinforced concrete has been successfully applied to moderately large spans. Most masonry bridges are under 150ft. span. The segmental and elliptical arches are preferably used for the wider spans of moderate height, while the semicircular arch gives better æsthetic effect when carried on a number of high piers. The treatment of the voussoirs has considerable effect in emphasising the magnitude of an arch. In the best bridges, the shape of each is apparent, and the individuality accentuated. In bridges like the Grosvenor over the Dee there is a heavy moulding on the arched ring, and the separate voussoirs are not distinguished. In the Dean Bridge, Edinburgh, an outer rib has been used beneath the footpath. This construction is a convenient one to apply in widening, as in the case of the bridge over the Rhône at Lyons. Another method, adopted in the Clyde Bridge at Motherwell, is to bracket out the widened portion on the face of the arches, but the former method is



LEOPOLD BRIDGE, LIÉGE. ENLARGED DETAIL.
The chief feature is the statuary of human figures on the piers. They are of varied designs. The voussoirs are accentuated, the coping being distinct and the springing clear. There is a well-defined cornice to the camber of the roadway. Sculpture work on piers and approaches is a feature of Continental bridges rarely seen in Britain.

---

*Extracts from a paper read by Mr. Robert Boyle, B.Sc., before Glasgow Association of Students of the Institution of Civil Engineers.



MAIN BRIDGE OVER THE NILE AT CAIRO.

This was recently completed by Sir Wm. Arrol and Co., Ltd., whose design was accepted in an international competition. Special attention had to be given to æsthetic effect. The curvature of the bottom boom of the main girders is appropriate, and the cast-iron parapet, with rest and light standards, enhances the appearance considerably. The architectural treatment of the abutments was by Mr. R. W. Paul, architect, London.

certainly æsthetically superior. In the case of a number of arches it is sometimes doubtful whether it is better to keep all the crowns on the same level or to keep the proportion of rise to span constant all through. The latter is perhaps better, and it admits of a gradual rise to the centre of the bridge or a camber on the parapet. In the best examples of arch construction the springings at each pier are on the same level.

In steel arch types there are three main divisions:—

1. Those which may be regarded as flat ended. The rib is continuous and generally increases in depth towards the abutments, as in Blackfriars Bridge.

2. Those in which the rib is continuous and is pin-ended or hinged at the abutments only, as in the Zambesi arch, Garabit viaduct, and the bridge over the Rhine at Bonn.

3. Those in which the rib is in halves, and is hinged at both crown and springings, as in the Alexandre III., Paris, and the new bridge, "De Smet de Nayer," at Ostend.

Blackfriars Bridge.

The piers are surmounted by cylindrical columns composed of polished red granite, with pediments and capital of Portland stone. They have the appearance of being immensely strong, are too short and stumpy, and have little reason for their existence. The piers would have been better treated like London Bridge. The correct treatment of the face of a pier is that of a buttress to take the thrust, not a weight-carrying member with no weight to carry. The face ribs are of wrought-iron covered with ornate cast-iron fascia. The cast-iron work on the spandrels is commonplace, and the placing of cast-iron rosettes at intervals along the web is wanting in engineering dignity.

Waterloo Bridge.

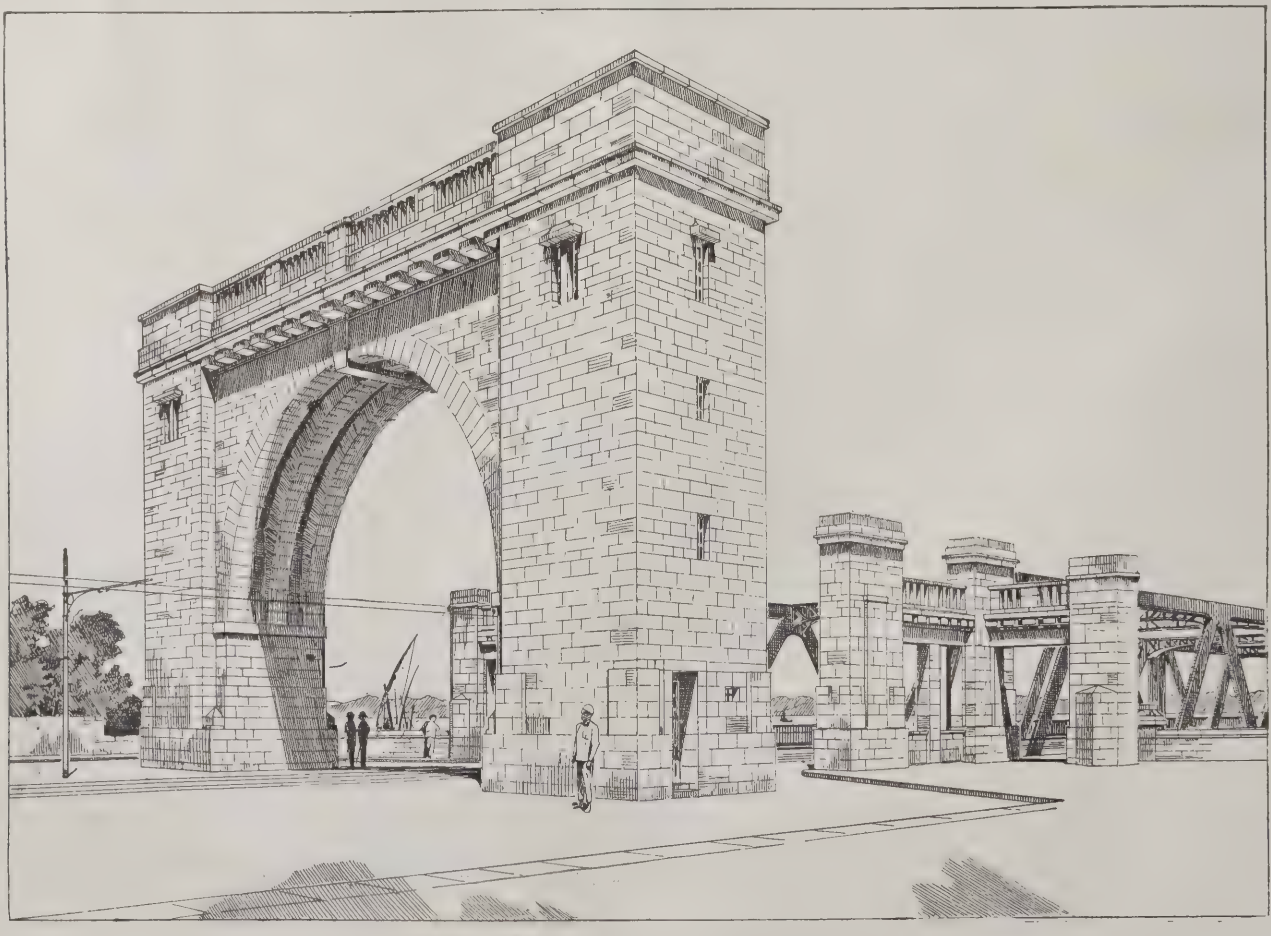
The design is excellent. The arches are semi-elliptic and the keystone is not accentuated. Nothing has been gained in appearance by surmounting the piers with two severely classic Doric columns, supporting an entablature. They are, however, plain and unobtrusive. The balustrade is finely detailed. The lamps would perhaps have been better over the piers instead of over the keystone, though they emphasise the centres of the spans. The whole structure, however, is remarkably graceful and beautiful, though practically level throughout its entire length.

London Bridge.

The treatment of the arch is suggestive of great strength and simplicity, and the whole design is chaste and harmonious.

Great Western Road Bridge, Glasgow.

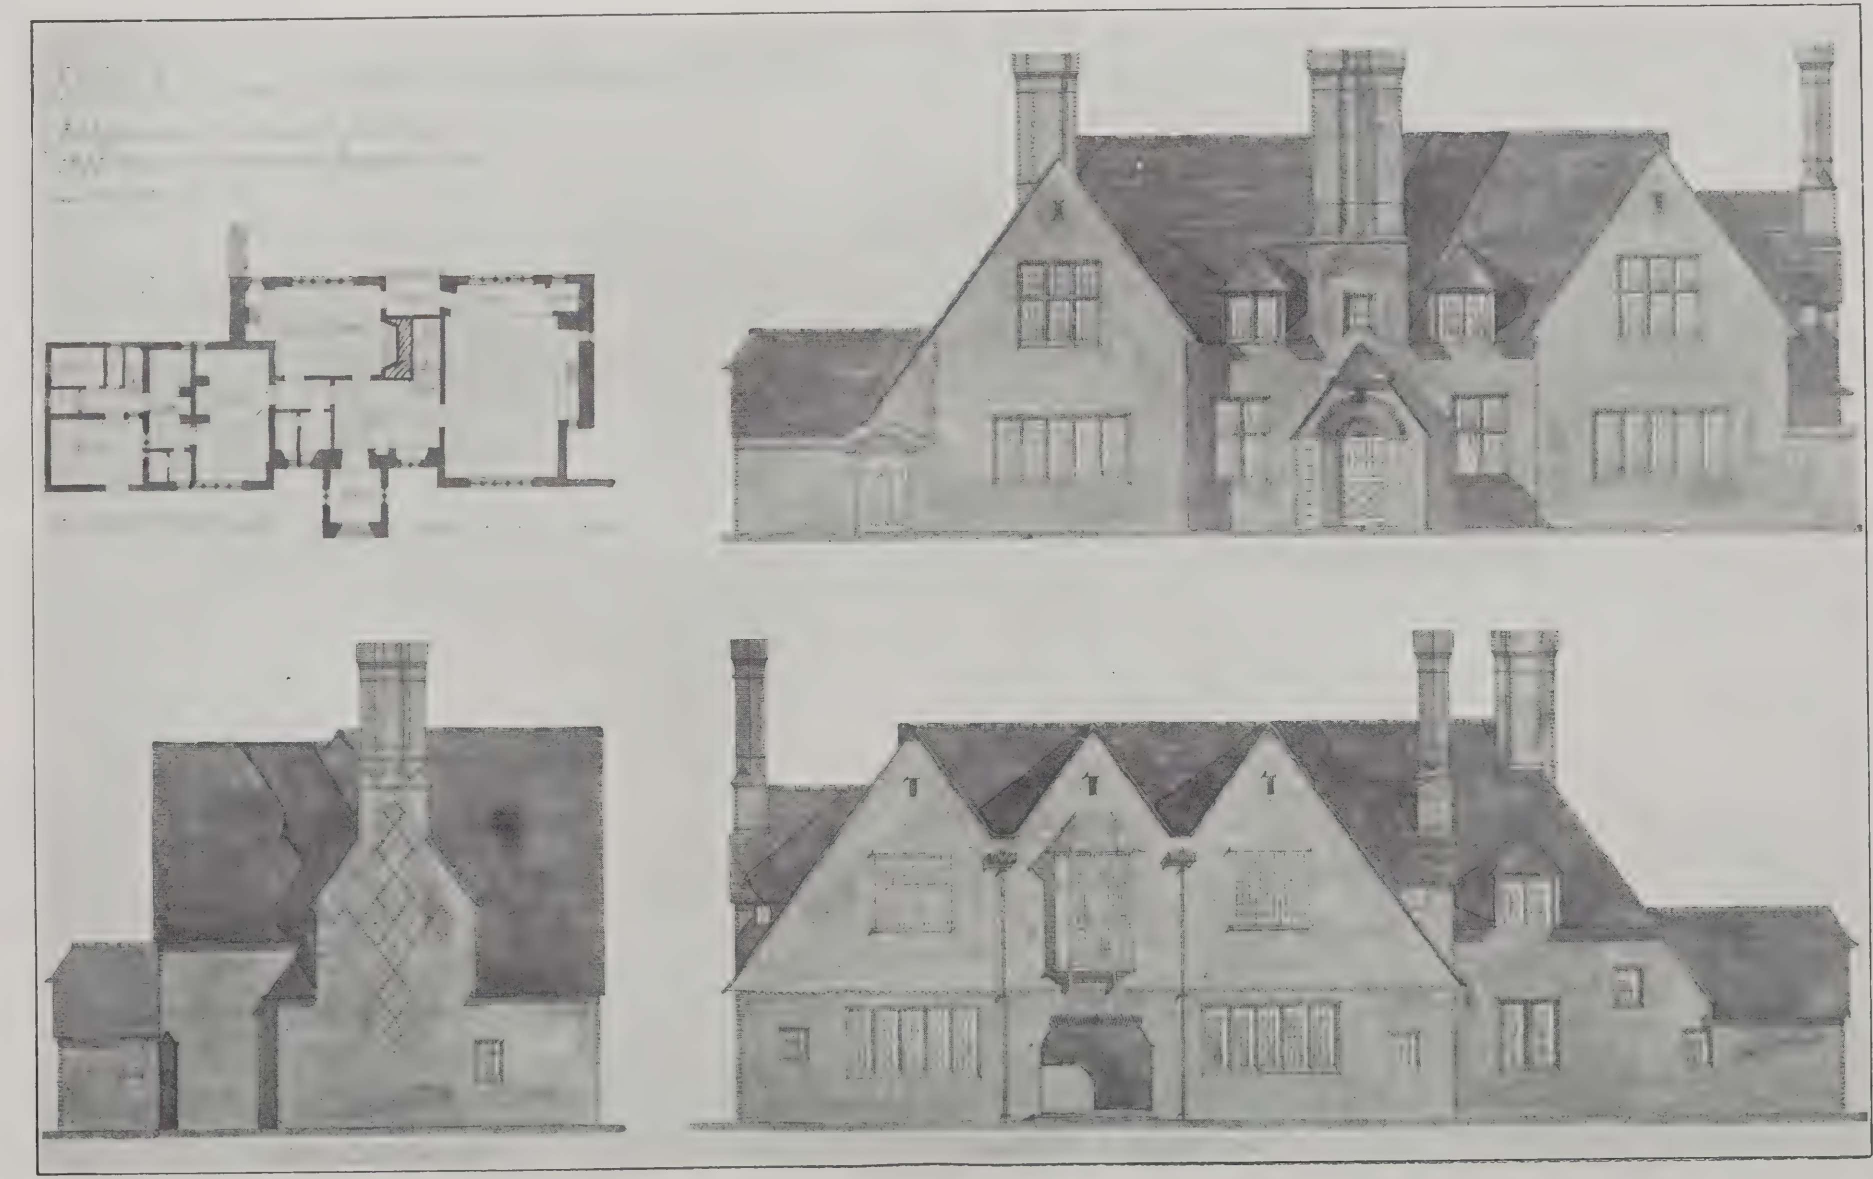
The moulding as applied to the metal rib is open to criticism. The treatment is Gothic in the pillars on the faces of the piers, and in the cast-iron geometrical tracery in the spandrels. The latter does not blend with the cold heavy cast-iron parapet, nor with the panels which take the place of the tracery in the two side spans. The Glasgow

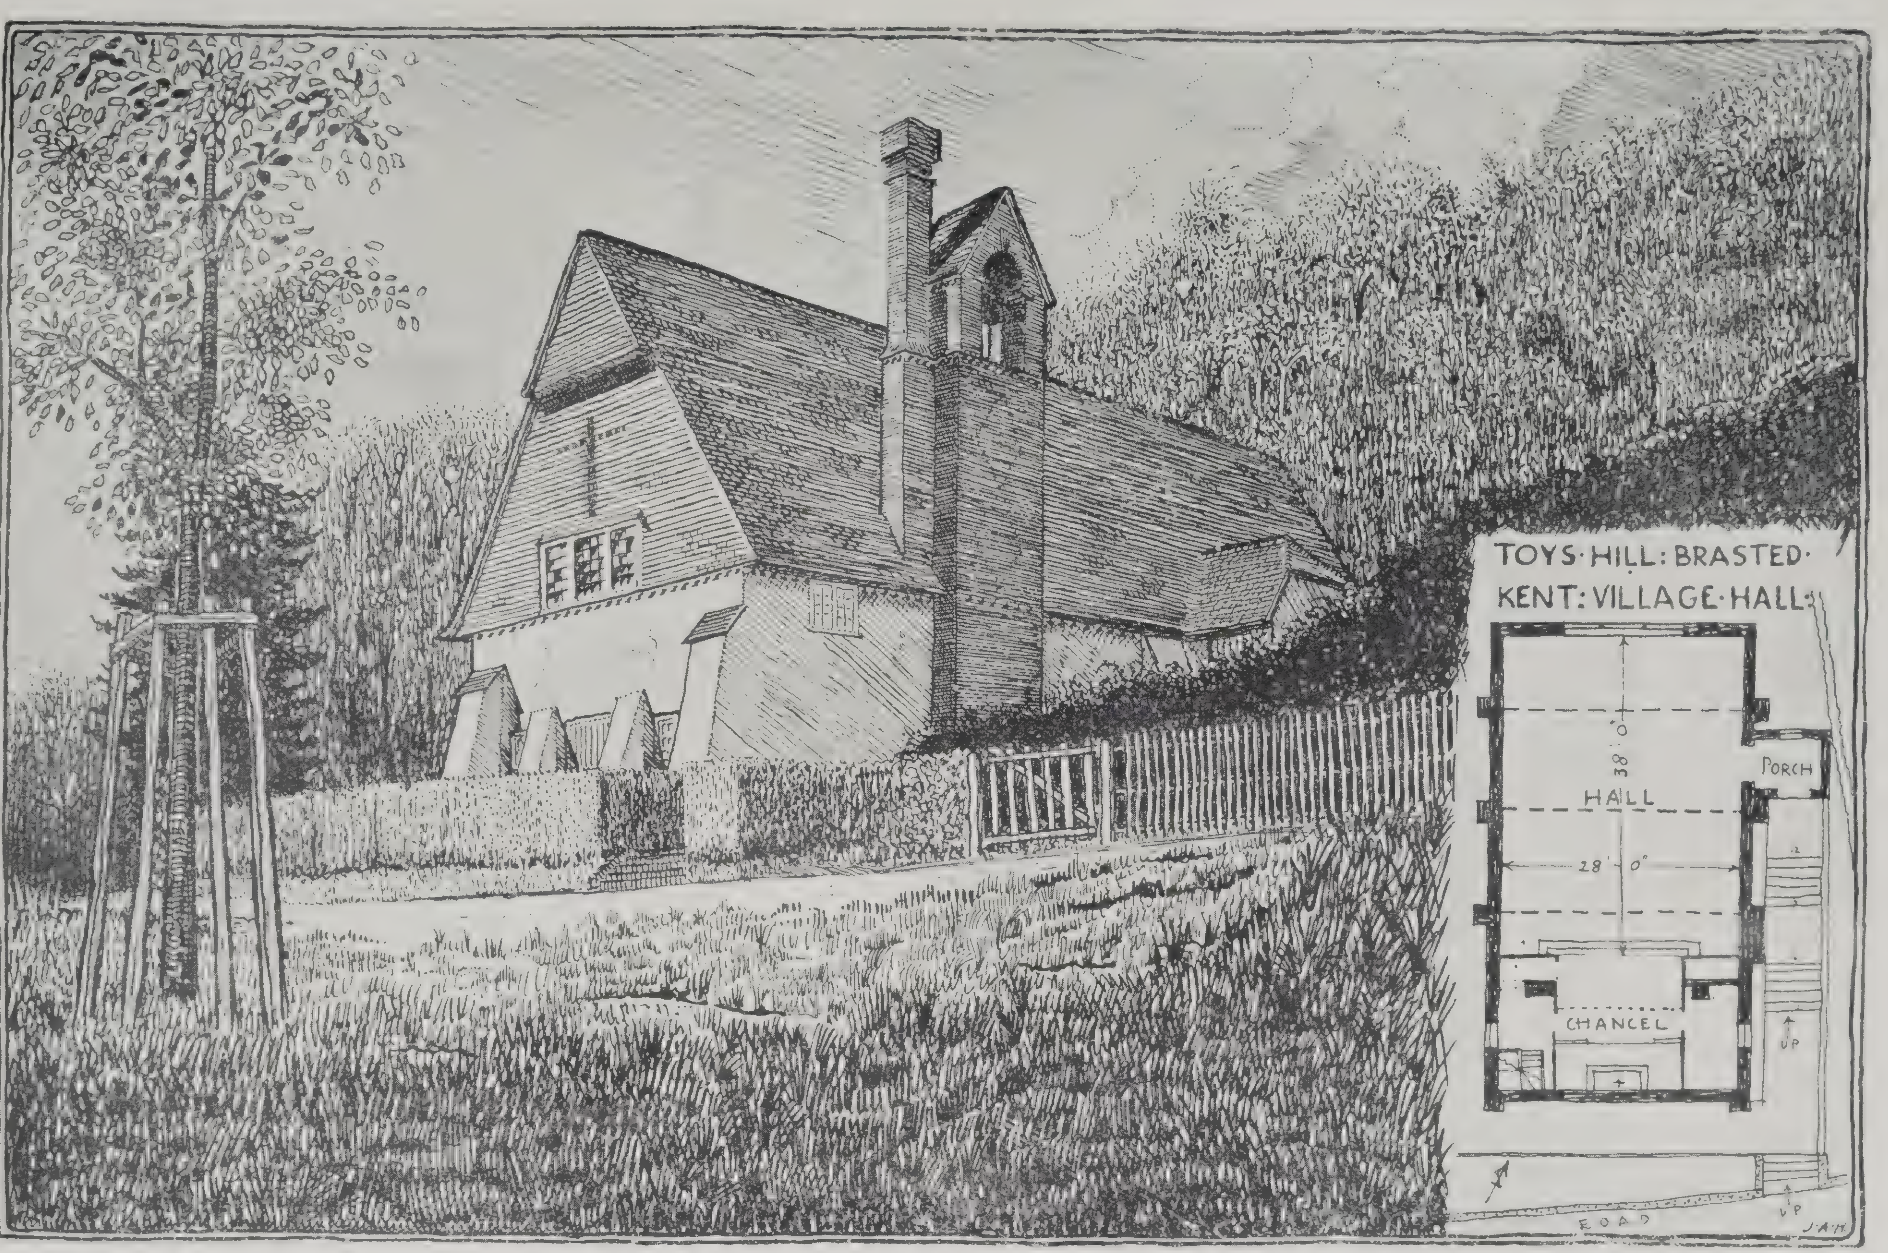


BRIDGE OVER THE NILE AT BOULAC, CAIRO.

This is an instance of the collaboration which ought to take place between engineers and architects. The sketch of the abutment with granite arch was prepared by Mr. Roland W. Paul, architect, for the engineers.

LIBRARY
OF THE
UNIVERSITY OF ILLINOIS





J. ALGERNON HALLAM, ARCHITECT.

[illegible]

coat of arms on the spandrels is gaudy, out of scale, and inappropriate. The piers are carefully proportioned. The Lendall bridge at York is of cast-iron, and is similar in Gothic treatment. It is beautifully symmetrical, but the cornice is unfortunately interrupted by the arch ring.

Broomielaw Bridge, Glasgow.

The general effect is good. The arch is of uniform ring stones with chisel draft on all the edges, while the spandrels preserve the megalithic character. The piers have octagonal ends, supporting octagonal counterforts.

Le Pont Alexander III., Paris.

This bridge is the joint product of an engineering firm, architectural firm, and three or four of the leading sculptors of the time. The proper place for monumental architecture on a bridge is, as here, on the approaches. Two magnificent pylons flank the entrance at each end, and are fine examples of excellent design. The structure would probably have looked better with small subsidiary arches instead of the ornamental festoons, but the beauties of the bridge are inherent in its curve and outline, its graceful air, its correct proportion.

Type III.—Bowstring Girders and Combinations.

Saltash Bridge, Plymouth.

The towers do not sufficiently balance the ironwork. The upper part of the centre pier is of cast-iron, and was constructed lighter because the foundation was about 100ft. below water level. The difference in construction is therefore justified. The upper parts of the girder are too massive compared with the chains and bracing.

Broen over Sarplossen, Sarsborg.

A roadway is carried below which detracts from the appearance. The piers might have been improved by being treated like the Saltash ones

Type IV.—Parallel Girders.

Britannia Tubular.

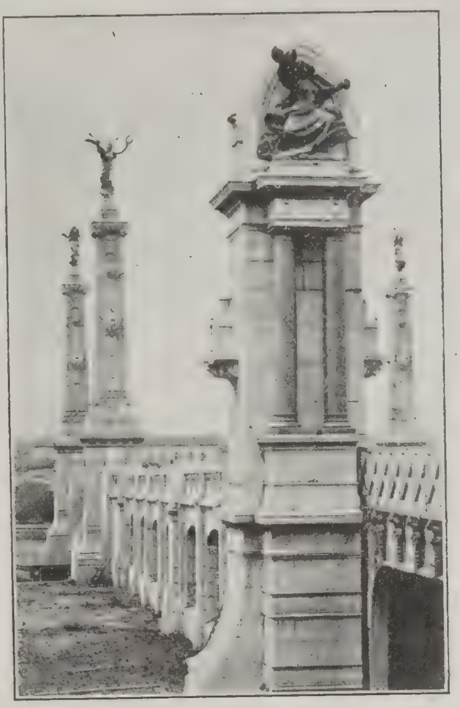
It was pointed out by Sir B. Baker, in discussing "The Æsthetic Treatment of Bridge Structures," that the piers of this bridge were built to admit of chains being used during erection, and perhaps afterwards in addition. It is rather remarkable that a bridge designed for suspension chains which were never erected should be such a fine piece of architecture, and that its prominent features should be largely redundant. It is difficult to say whether the girder is divided or continuous, but the concealment is with artistic effect.

New Caledonian Railway Viaduct over the Clyde at Glasgow.

The piers are substantially treated. An ornamental lattice parapet, with cast-iron cornice, cope, and rosettes, is carried out from the outer main girders on ornamental steel brackets. The appearance is graceful, but the rosettes at the intersections might have been better dispensed with.

Type V.—Cantilever Bridges.

These consist essentially of four divisions. 1.—Those with horizontal lower boom, like "Le Pont Doumer sur le Fleuve Rouge" at Hanoi and the Connel Ferry. 2.—Those with horizontal upper boom, like the Poughkeepsie, New York. 3.—Those with both booms inclined, like the Forth. 4.—Those which are arched and are of the type known as "constrained cantilevers," of which the Viaur viaduct, "le pont Mirabeau," and Dalginross bridge at Comrie are examples. It is wrong to attempt to hide the break in continuity at the junction of the central girder and the cantilevers. Nothing could be worse than attempting to imitate or suggest an arch or a suspension bridge by reducing the depth towards the centre of the suspended girder. It is uneconomical and a violation of the fundamental principles of æsthetics. It is admissible, however, in cases like the Nile Bridge at Cairo and the Harvard Bridge, where the arch is very flat at the suspended girder.



THE NEW BRIDGE, OSTEND.

The view shows the decorative treatment applied to the piers. The succession of high piers crowned with statuary is a very prominent feature on the roadway.

Forth Bridge.

The perspective effect is distinctly good. The batter of the piers in the transverse direction is very tasteful. Ornament on such a bridge would be out of place. The curvature of the lower boom is an excellent feature. Fitness for duty has been the primary consideration, and the bridge, though not pretty, is grand, imposing, stupendous.

Our Plate.

Sketch for the Red House in Hitchin.

This is a sketch designed for a house proposed to be built with small uneven bricks unpointed, the roofs to be covered with dull red hand-made tiles, the windows to have iron casements, lead glazed, in brick mullions and transoms. The three gables to garden are to be covered with rough oak boarding, the window frames in these gables being oak, also the oriel on staircase landing. Mr. J. Algernon Hallam is the architect.

Village Hall, Tongs Hill.

Tongs Hill is a small hamlet about 3½ miles from Westerham. The hall will be on a hill-side, the large gable looking across the weald. The point of view of the sketch is on the road coming up the hill from Edenbridge and Four Elms. The road turns right and left in front of the hall, the small bell gable pointing up the hill along the road. Owing to the steepness of the site, the hall proper is at the first floor level, brick steps externally leading up to the porch. In front on the ground floor will be a small kitchen and heating chamber. The altar and back part of the stage will be consecrated and shut off by a movable screen, there being no church at Tongs Hill. The hall will have to serve for entertainments, and also for purposes of worship. The walls will be covered with rough plaster, the roof covered with hand-made tiles, and the bell turret will be constructed with small bricks unpointed. It may be mentioned that great interest is being taken locally in the hall; the farmers are going to cart materials from the station up the steep hill to the site, digging for foundations, etc., is also being done gratuitously. Mr. J. Algernon Hallam is the architect.

London Suburbs.

Kilburn and Brondesbury.

The change that is passing over the outlying provinces of our enormous capital can nowhere be better studied than in the Kilburn High Road. Approaching it by Maida Vale, which not many years ago was sufficiently far "out" to be quite suburban, with its roomy, handsome Palladian villas and deep gardens, from which there has been a sudden exodus caused by the din and dust of the motor traffic, we turn into Kilburn, close to the site of the old turnpike gate from which Dick Turpin started on his ride to York. Although we are going away from "town," we come not to green fields, but to a district whose inhabitants considerably outnumber those of some manufacturing towns; the High Road is densely crowded with foot traffic, and on Saturday nights is almost impassable, and one of the sights of London; yet a few yards away on either side are quiet suburban roads, and the visitor is driven to ask where the multitudes of people, and especially of working people, live. He will find out by exploring the roads that run beside the London and North-Western Railway, and penetrating into "purlieus" of little cottages behind the main road; a medley like the road itself, and mostly very small, an extraordinary instance of the fortuitous, haphazard growth of later London.

Broadly speaking, the neighbourhood may be divided into two sections, one of which, Kilburn, is built in the style of the "forties" and "fifties," and chiefly faced with stucco; the other, Brondesbury, presents the inevitable red brick fronts and roofs with dormers suggestive of bad upper rooms; it spreads far to the north-west and touches Willesden Green and Cricklewood. The narrowness of the foot pavement of the Kilburn High Road is very inconvenient, but no one seems to have anticipated the growth of the suburb. As we look down its length a very recent change obtrudes itself harshly; this is a procession of telephone supports rising above the roofs: it would seem that in the near future there will be no outlines left to anything. Cannot electrical engineers and architects find some other place for their system?

As usual, the local offices of well-known banks stand out rather conspicuously, but take it for all in all the great main thoroughfare of Kilburn is, architecturally speaking, a mere patchwork, and the road itself too narrow. Actually a town has grown up and cannot find accommodation in a suburb. Public buildings are few and unimportant, though the lofty tower and spire of St. Augustine's, Kilburn, dominate the neighbourhood—a building too well known to need description here. Hard by is the little church of St. John's, whose interior, with its apse, good adaptation of a small clerestory and simple nave arcade, are worth a visit, if only to justify the Victorian architects in their love of English Gothic.

Between the two Kilburn stations there is a length of about a mile of High Road, which is characteristic of Kilburn; there is the comparison of styles of building, never assuming any definite form or the style entirely of our own age so often promised, and there is, unfortunately, the endless disfigurement by gigantic lettering of names of firms, besides advertisements, one or two clothiers leading the way in spoiling Kilburn as a leading house agent spoils West Hampstead. All legitimate purposes of trade could well be served without this exaggeration and repetition. In spite of all defects, however, the suburb is a popular one, and the High Road still retains two pleasant features—the yard and buildings of the Kilburn Brewery and the fine trees of the Grange Elms, a low, rambling house in modern Gothic standing in fine grounds, but the last of its kind left in the district.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himself of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable and it must be understood that both question and reply will, as a rule, be published in these columns

Sub-contract Tendering.

CHESHIRE. — TEAK writes: "A builder A has tendered for the erection of a building, but wishing to sub-let one of the trades before himself tendering, he sent out copies of the quantities for this trade, and based his own tender on the price received from B, being the lowest for the trade in question. Having secured the work and signed the contract, he finds, on offering to accept B's price, that B is not willing to do the work. A must perforce go on with his contract, and to do so will have to accept the price for the sub-contract next higher than B's. Can A recover the difference between these two amounts from B? The time which elapsed between receiving B's price and the offer to accept same was three weeks. In tendering, B did not state that he agreed to do the work for that amount if called upon to do so, but simply that his price for the work according to quantities was so much, and signed his name at the foot."

The above question can be answered by a study of the law relating to tenders. When does a person make a tender? A tender is really an offer to do work at a certain price. An offer can be withdrawn at any time before acceptance (*Routledge* v. *Grant*, 1828, 4 Bing., 653), but not afterwards. In other words, a concluded contract comes into existence as soon as a tender is accepted (see, generally, "Emden's Building Contracts," 4th edit., p. 19, et seq.). Applying these principles to the above facts, it seems clear that B was bound to make good his tender as soon as the same was accepted. The fact that he did not use the word 'tender' in making his offer is immaterial, for it was decided in *Crawshaw* v. *Pritchard*, 1899, 16 T.L.R., 45, that where builders wrote,—in answer to a letter inviting a tender:—"Estimate.—Our estimate to carry out the sundry alterations to the above premises, according to drawings and specifications, amounts to the sum of £1,330," and this tender was accepted, they were held liable in damages for refusing to carry out the work. This principle probably governs the present case. It would seem that the only defence B could raise to a claim for the difference between his tender and the next lowest would be that it was an implied term that the acceptance was to be communicated within a reasonable time, and that a delay of three weeks was too long. In law, the courts would doubtless hold that the tender must be accepted within a reasonable time; and what is a reasonable time is a question of fact. *Prima facie*, three weeks ought to be regarded as a reasonable time in this case. BARRISTER.

Rights of Extension of Premises.

LIVERPOOL.—P. D. writes: "In the accompanying sketch [not reproduced] is A allowed to extend his premises to line of iron railing? The portion enclosed with iron railing belongs to him. Both A's and B's shops are very old. Also in the second sketch [not reproduced], is A allowed to build the proposed extension, two storeys (about 19ft.), to eaves? Is there any new law as regards right of light in this case?"

I understand these sketches to refer to entirely different frontages and circumstances. First case.—There is no reason at all why A should not bring forward his shop to the line of the iron railings and of the property adjoining, but to avoid friction, I advise him to let his neighbour B see the drawings before he commences work. Second case.—This is a great deal more difficult than the other case, and I rather doubt whether the extension can be built. The answer to the question depends on the following:—(a) When the proposed new building is completed, will there be left at the rear of A's premises the sufficiency of air space required by the local by-laws? (b) Will the new building materially interfere with the light which B now enjoys through all or any of his three windows? (c) Has C any right of light to his property? No change has recently taken place with regard to the law of easements affecting light and air. Twenty years' enjoyment gives a right which cannot be interfered with, but the damage suffered must be substantial and not of merely a trivial character. F.S.I.

Workmen's Compensation Points.

PROVINCES.—DOUBTFUL writes: "A is a retired builder, and owns a piece of building land upon which he has decided to erect some dwellings; he gave one of his old hands a job to get out the foundations ready for the brickwork, and of course was liable under the Act should an accident have happened to him. This man is now discharged, having finished his job. A decides to let all the labour required in the erections to separate men under the several trade heads, the brickwork at so much per rod, the carpenters, slaters, plasterers, etc., at so much per house; A will provide all necessary materials, but not plant or scaffolding; the respective contractors will each engage what help they require. Kindly give your opinion on the following points:—1. Is A responsible for any claim if any of the workmen meet with an accident at his work on any of these buildings? 2. If so, to what extent, as a principal or otherwise? 3. Seeing that only the brickwork is let at per rod, which is commonly spoken of as piecework, would the liability, if any, be removed by letting the brickwork at per house?"

The answers to the questions above propounded depend upon S. 4 of the Workman's Compensation Act, 1906. To put the matter shortly, A is liable, subject to an indemnity. The Act provides that (1) where any principal . . . contracts with any contractor for the execution by or under the contractor of . . . part of any work undertaken by the principal, the principal shall be liable to pay if that workman had been immediately employed by him . . . (2) Where the principal is liable to pay compensation under this section, he shall be entitled to be indemnified by any person who would have been liable to pay compensation to the workman independently of this section, and all questions as to the right to and amount of any such indemnity shall in default of agreement be settled by arbitration under this act. The only exception to the liability prescribed by this section is contained in SS. (4), which is as follows:—"This section shall not apply in any case where the accident occurred elsewhere than on, or in, or about premises on which the principal has undertaken to execute the work, or which are otherwise under his control or management." It is thought that this sub-section would give but little relief to "Doubtful," inasmuch as the premises would clearly remain under his control and management. BARRISTER.

The committee promoting the erection of a memorial to the Pilgrim Fathers at Southampton have selected a design involving an estimated cost of £2,000. The scheme embraces the erection of a monument on the Western Shore, a corbelled projection in the form of the prow of a ship.

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Sept. 1.	NEWBURN. Council Chamber Offices and Caretaker's house. The Newburn U.D. Council invite designs for these buildings to be erected in Newburn Lane, Newburn. Open only to Architects practising in Newcastle upon-Tyne and in the County of Northumberland. The author of the design considered the best will, subject to the general instructions and conditions of the competition, be employed to carry out the work. A premium of £10 will be awarded to the author of the design considered second in the order of merit. The Council has appointed Mr. Richard John Leeson, of the firm of Oliver, Leeson, and Wood, of Milburn House, Newcastle-upon-Tyne, architects, as assessor. A plan of the site and a copy of the general instructions and conditions of the competition may be obtained from George Wilkinson, Clerk to the Council, 1, Mosley Street, Newcastle-upon-Tyne, on payment of a deposit of One Guinea, which will be returned on receipt of a *bona fide* design, or if the plan of the site and copy of the general instructions and conditions are returned within 14 days with a notification of non-intention to compete. The designs are to be delivered at the Clerk's Office, No. 1, Mosley Street, Newcastle-upon-Tyne.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.
Oct. 11.	HULL TRAINING COLLEGE for Teachers in Elementary schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd, and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.
Nov. 30.	HERNE BAY PAVILION ON PIER. Herne Bay Urban District Council invite competitive drawings for a pavilion to be erected on the proposed extension of the pier at a total cost not exceeding £4,000, exclusive of architect's commission. Premiums of twenty-five guineas and ten guineas respectively will be awarded for such two designs as shall be judged of sufficient merit by the Council, and placed by them as first and second; the premium of twenty-five guineas to be afterwards merged into the usual commission payable to the architect, provided the work is carried out by such competitor. Plan of the site and copy of the conditions may be obtained on application to the undersigned on and after the 24th instant on payment of one guinea, which will be returned on receipt of a bona-fide design. Drawings to be deposited at the Clerk's Office, Town Hall, Herne Bay, not later than noon on the 30th November next.—Joseph Jubb, Clerk to the Council, Town Hall, Herne Bay.
No date.	NATIONAL MUSEUM OF WALES. The Council desires to receive competitive designs for the erection of a new National Museum at Cardiff. Three premiums are offered. The Council have appointed Sir Aston Webb, R.A., Mr. John J. Burnet, A.R.S.A., and Mr. Edwin T. Hall, F.R.I.B.A., as Assessors. Particulars and plans of the site will be supplied to competitors on payment of a fee of £2 2s., which will be returned on receipt of a design in accordance with the conditions, or if all papers are returned within 14 days. Inquiries to be addressed to Dr. Wm. Evans Hovle, Director of the Museums, City Hall, Cardiff.

Builders' Notes.

Foreign Granite.

It is probable that the question of British versus foreign granite will be, like the poor, always with us. This vexed topic has been re-opened now that the Government is asking for tenders for the granite required at the Rosyth Naval base. The Scotch quarry owners on the last occasion quoted what were regarded as extravagant prices. As a result the contract went to Sweden, the price accepted being some £20,000 less than that demanded by the Scotch firms. There are reasons, considering the higher wages and shorter hours of British workmen, why these things should be; but it is doubtful whether the powers that be appreciate the significance of the situation.

* * *

Germ-Killing Paint.

Nowadays most chemical inventions come from Germany; and it is not surprising, therefore, to learn that a new germicide paint has been invented at Chemnitz. It is called "Vitralin," and, in the report which has reached us, is said to have a basis of white lead or zinc white, or, in other words, is compounded on the lines of ordinary paint. The specific disinfectant property of "Vitralin" results from the oxidisation of the linseed oil, "which forms an important constituent of the paint. The bacilli of several forms of dangerous disease were brought in contact with it, and it was found that the germs of tuberculosis are completely destroyed in three days, while the germs of diphtheria went under in five hours, of typhoid fever in eight hours, and of pus in from six to thirteen hours." No lethal effect, however, could be observed upon the spores of anthrax, even when contact lasted 30 days, although a distinctly retarding influence upon the development of the spores was noticed.

* * *

Fireproofing & Foolproofing.

The fatality at a cinematograph exhibition at Southsea lends point to the aphorism that while it is difficult to render a building fireproof, it is impossible to make it foolproof. It appears that a film flared up, but was promptly extinguished, and all would have been well but for a foolish cry of "Fire!" The assemblage consisted mainly of children, who at once became panic-stricken, and rushed for the doors, when, a baluster giving way under the severe pressure, a little boy was killed. Similar accidents have been very numerous, and it is hardly possible to suggest any practicable means by which they may be prevented. Where the crushes have been known to occur in passages or on staircases that were narrow or crooked or both, the remedy was obvious; but, seeing that people occasionally crowd each other to death in open streets and in large squares, it is obvious that the only possible means of preventing such calamities is less a matter of planning than of police.

* * *

The Out-of-date Death-trap.

Without reference to the Southsea case, but speaking quite generally, it is to be feared that, in various provincial towns, there are many out-of-date buildings that, being used regularly or occasionally as places of public assembly, would become terrible death-traps in case of panic. The writer of this note was present the other evening at a small country theatre which a vigilant authority like the London County Council would instantly close. Built in the old pre-scientific days, it consisted largely of unprotected woodwork. The exits were few and narrow, and there were passages that seemed to have been very ingeniously planned with the express object of obstructing egress; and there was no evidence of a fireproof curtain. Although the theatre was filled to suffocation (and, by the way, means of ventilation seemed to be non-existent), the audience numbered only about 300 or so; but the tediously long time it took to filter out suggested the horrible conviction that if ever that theatre takes fire during a performance, there will be a repetition of some very ghastly history. As remarked in the immediately preceding note, it may be impossible to make a public building absolutely panic-proof; but, happily, it is possible, by the employment of modern methods, to ensure almost perfect immunity from fire; and the knowledge that these methods are rigorously insisted on, as they assuredly should be, by the responsible authorities, will go far towards extinguishing, at least among adults, the now too common tendency towards panic. People who have acquired confidence that a building is so constructed as to be but little likely to catch fire, that at the worst the fire would spread very slowly, and that the exits are plentiful and practicable, will not kill each other in a mad attempt to escape from death, and will not be greatly addicted to or readily influenced by either false or true alarms. It is the manifest duty of local authorities to establish this confidence by the strictest enforcement of the best-conceived regulations for protection against fire and panic. It is their duty to act on the knowledge that the "death-trap" building is out of date.

* * *

"Building for all Time."

A correspondent of the "Liverpool Daily Post," writing under the suggestive cognomen of "Stonehenge," asks a pertinent question about the stone that is being used for the new cathedral. He asks for evidence "that the chemical and hydraulic tests applied prove the stone (red sandstone) to be one which actually hardened with the weather. Some," he says, "will be inclined to doubt that statement in face of the rapid efflorescence," noticed on other buildings in the city. The effect of the sea air, the various gases, and sulphurous fumes, I am afraid, will make one sceptical that any modern building is 'for all time.'" The preservation of our cathedral fanes is exacting unremitting care and vigilance; but their age and, in some cases, not very stable construction, are adequate excuse for the frequent repairs that are necessarily demanded. But if the air of Liverpool is already acting with deleterious effects upon recent buildings, it would seem to possess quite extraordinary potency. We prefer to believe that "Stonehenge" is of the numerous army of alarmists.

* * *

The Belgian Builders' Visit.

The party of Belgian builders have, we hope, had an interesting and jovial holiday on our shores. Certainly the account of the London dinner, which we reported last week, and the particulars of their doings in Liverpool and Sheffield, which are given in another column, lead one to believe that our guests had a thoroughly good time, and that the way has been further paved for a better understanding between the British builders and their confreres of the Continental nations. The visit has not been without its humorous phases, one or two of which found their way into cold print. One story that is immensely rich concerns the two Yorkshire builders, unknown to each other, who commenced a conversation in "alleged French," each being under the impression that he was addressing a Belgian confrere. The mutual horror and disgust of the two when the inevitable mental tangle occurred, and one of them disclosed his nationality by regretting the absence of his dictionary, may be better imagined than described. Another little incident occurred on the steps of the Sheffield Town Hall, where a well-known local builder was asked what he thought of his own city, and was recommended to look at the new post office by some enthusiastic fellow-citizen who happened to be passing, and who hurried away before his victim could recover from his very natural amazement. These little incidents tend to the gaiety of nations, and we trust that they are not apocryphal, although they "come fra Sheffield."

* * *

Small House Inspection.

The clause in the Housing and Town Planning Bill which provides for the inspection and registration of all small houses is to be strenuously opposed by the Association of Municipal Corporations. This inspection and registration, it is proposed, shall be carried out by the local authorities once in five years. Opposition is based on the ground that the authorities already possess powers in this direction, and any further enactment would only result in needless waste of the ratepayers' money. Mr. T. C. Horsfall writes to "The Manchester Guardian" drawing attention to the danger to the measure which the elimination of this clause would entail, and emphasising the importance and value of its application. With this sentiment we are in entire agreement. It is beyond question that numbers of people invest money in small property who are not fitted to hold it because their means will not allow of their keeping it in a proper state of repair. They live on the rentals until the property sinks in such a condition of dilapidation and want of repair that the sanitary officials condemn it and obtain a closing order. But though this may end the evil itself, it by no means checks the mischief which the existence of such property exercises upon its surroundings. Slums drive respectable people from property in the vicinity, and deteriorate an entire neighbourhood. The damage they inflict may be out of all proportion to their own value and extent. It is therefore a matter of some importance to see this clause retained; and from the builders' point of view it should be an advantage to have these periodical repairs and redecorations carried out. The speculative builder, too, may suffer loss in the development of an estate if the first houses built and sold by him are in the hands of small landlords, who allow the property to go to rack and ruin to the detriment of the new dwellings he is erecting. Mr. Horsfall does not hesitate to say that while some cases of bad housing may be attributed to the negligence of owners, very many are due to the bad habits of wilfully careless and destructive tenants, upon whom this periodical inspection would prove a wholesome check. The system of inspection of all small dwellings is now in use in Hamburg, Lubeck, Hessen, Alsace-Lorraine, Saxony, Baden, Bavaria, Wurtemberg, and in the Rhine Province of Prussia. Wherever it has been tried it has been found to be the necessary foundation for a really effective attack on bad housing. The following statement respecting the results obtained in Dresden fairly represents the tenor of the annual reports issued in all the towns and states which are named:—"The last report on the inspection of dwellings in Dresden is also very encouraging. Dresden has 136 000 dwellings and over 400,000 inhabitants. There are twelve inspectors of dwellings. Ground plans of all the houses have been prepared, and in future examinations of all the dwellings can easily be completed in about six months. The inspectors report that inspection is more and more welcomed, both by landlords and tenants, and the inspectors receive more and more requests for their intervention, advice, and suggestions. It is their object to be regarded as friends and advisers rather than as police officials. They report that, while many of the dwellings are too small, most of them were clean, and that only five dwellings had to be emptied on account of lack of cleanliness. In all other cases, when some want of cleanliness was objected to, improvement was effected without delay."

The Age and the Style. Mediæval architecture is based on the idea of vertical expansion, classic architecture on the idea of lateral expansion. The desire of the one is to rush up: of the other is to spread. Can we say that the tendencies of architecture stand for certain tendencies in human nature? Yes, on the whole, is the answer. The Middle Age, with its love of action and belief in its all-sufficiency, is the time of the birth of pointed architecture. Chivalry and romance, poetry, the Crusading frenzy, and Gothic architecture, one after the other, emanated from France—the impulse, that is, to consecrate and idealise a love of action; indealised energy, in fact. Gothic architecture was the typical child of the mediæval age, an age poor in thought and rich in energy. And Gothic architecture must therefore have the defects of its age. Only what can be got out of life can be put into art. The energy which characterises mediæval life we find in the architecture. If lack of thought equally characterises that life, we shall find that in the architecture, too. The Doric temple, the laterally expanding in style, the supreme example of horizontal architecture, is essentially the product of an age of thought, of an age just as fully charged with thought as the mediæval age is charged with energy. Classic architecture, as developed under Rome, had many bad qualities, but one fine quality—its spacious and ample proportions: proportions in which are measured for us the qualities of the classic mind and which produce upon us something of the same calming effect which contact with the classic mind itself produces. The connection between spaciousness in architecture and a free play of the mind is still more plainly shown by the Italian Renaissance. In fact, we shall find that the accessibility or inaccessibility of various parts of Europe at various times to ideas is measured for us in the readiness of architecture in those parts to expand, or in its refusal to expand. Why is early Victorian art a bye-word—not of that which is good? After the French Revolution England was thrown violently back upon herself; she distrusted France, always receptive of ideas, more than ever; she contracted, as it were, and her insular prejudices and limitations reasserted themselves with vigour. This isolation took effect in many ways. It showed itself in the dullness and ponderous self-satisfaction of early Victorian society and early Victorian art. It showed itself, even, in the nature of the revolt against that dullness, a revolt which, far from interesting itself in contemporary European life and thought, busied itself in the resuscitation of our own dead ideals and in the mournful retrospection of the pre-Raphaelites. But, above all, this isolation, this severance from the life and thought of Europe showed itself in a passionate revival of Gothic architecture.

* * *

A Simple Test for Mortar. The following is said to be a useful test as to the quality of mortar:—A large pat of the mortar is placed on a clean shovel, the latter being held at a sharp angle so that the mortar may slowly slide down it. If the material is of good quality the metal will be covered all over the portions previously covered by the mortar with a whitish slime. If lumps remain on the shovel after most of the mortar has slid off, too little water has been used in the mixture. If, on the contrary, the shovel is covered with a film of dirty water and the mortar slides off too quickly, it is a sign that too much water is present—the mortar has been mixed too soft. Irregularly distributed white spots suggest that too little lime has been used, or that the mixing is defective. Very soft, easily spread lumps in the mortar indicate a lack of sand, but brittle portions show that more lime or lime and water is needed. Obviously this test demands considerable practical experience, and even then depends overmuch on the personal judgment of the man who makes it. Such rough-and-ready tests, however, are often valuable as being the means of bringing the operator's experience and judgment to a focus, or of concentrating his energies upon particular points. For this reason, if for no other, crude rule-of-thumb methods ought not to be lightly despised. They fix the attention in much the same way as in the case of the youthful Walter Scott, who could never recite his lesson unless he could at the same time fumble with a button.

* * *

Science and the Builder. That the common fund of knowledge of stresses and strains is by no means perfect needs no proof, and the need for amplifying it has been rather forcibly indicated by recent bridge failures, such as that at Quebec, and hardly less strikingly by the frank confessions by engineers of their ignorance on certain points that have only recently assumed practical importance. There is an urgent demand for data derived from actual experiment—as to the different effects, for instance, of various moving loads—and from careful observation of the effects of natural influences—wind, sun, heat, frost, etc. Concerning all these matters, and perhaps some others, the old data need revision and amplification, and it is not impossible that, in the course of properly conducted investigation, further facts and phenomena could be deduced or discovered. Such investigations should not be left to voluntary effort and private endeavour. Now that our universities are devoting more attention to scientific work, it may be anticipated that the experiments in which they engage will not be confined to barren repetitions of what has been already ascertained and established, but rather that they will partake more largely of the character of independent research, so that the recently widened gap between theory and practice may be reduced or bridged. With regard to loads, it is plain that this is a matter which closely concerns not only the engineer and the builder of bridges, but also the architect and the builder of warehouses, and other large structures in which modern methods are adopted. In this respect the conclusions that are to be, and doubtless soon will be, established, are likely to make for economy rather than for safety—that is to say, they will make for both, although since it is known that the present conditions err on the side of safety, the most valuable achievements in research may be expected to arise from demonstrable proofs that this essential object can be assured with less expenditure on labour and materials. The investigators will renew, on scientific lines, the ancient and inevitable quest of efficiency with economy. They cannot do it quite adequately, however, with the necessarily limited means afforded by the institution workshops and class-rooms. If science is to be really helpful to the builder, the builder must be really helpful to science. This he can be, without incurring much inconvenience, by affording facilities for the inspection of works in progress, and by referring interesting practical problems to the consideration of the trained and accredited expert.

THE WHITGIFT HOSPITAL CONTROVERSY.

Mr. John Burns, who, as President of the Local Government Board, may refuse to grant Croydon Town Council the powers to enable them to carry out improvements which would involve the destruction of the Whitgift Hospital, has paid a visit to the spot, and it is stated that, while his love of ancient buildings is well known, he favours the suggestion that the corporation should take the opinion of the ratepayers as to whether or not the hospital shall be cleared away. The Mayor of Croydon has stated that he and his supporters do not desire the destruction of the building, which, however, is situated in the busiest part of Croydon, in such a position as to prevent the widening and straightening of the main street. The Mayor sees no reason why the almshouses could not be pulled down, and re-erected on a more convenient site.

A curious compromise has been suggested by a correspondent to a morning newspaper. "He," says the 'Evening News,' "would settle the question by allowing the new road to cut off as much of the hospital as may be necessary. The demolished portion, he complains, might be set up somewhere else. 'Would not this,' he asks, 'meet the reasonable wishes of all concerned?' Now," comments our evening contemporary, "it is not a fact that the work of Elizebethan builders can be moved as easily as a galvanised iron cricket pavilion. But the peacemaker may be told that the peculiar beauty of the Whitgift Hospital does not lie in its bricks, which are very like any other ancient bricks. The beauty is there because the bricks were built up in the form of an Elizabethan house, enclosing a square garden court. Traffic at Charing Cross might be improved if we were to cut off the hind legs of Charles's horse, with their share of the stone pedestal. But even if we found room in Finsbury Square for the detached portion, there would be æsthetic and sentimental objections to the arrangement. We trust that we have now explained to the peacemaker why his Croydon plan would not 'meet the reasonable wishes of all concerned.'"

This compromise will not work. If there is to be a compromise at all, it may possibly be that suggested by active members of the Committee for the Survey of the Memorials of Greater London, who, we understand, point out that the requirements of the case might be met by continuing round the angle into North End the existing passage between hospital and the buildings adjoining it on the east, when a slight widening of the south side of the street would give sufficient space for the traffic. If the issue is to be decided by popular vote, we can only trust that the people of Croydon will make a right use of their opportunity for showing that they are not destitute of veneration and true taste. We admitted, last week, that there is some force in the argument that the hospital is obstructive to street widening. This situation, however, has been created by the local authorities, who, from time to time, have sanctioned street plans that have gradually led up to the present position of affairs. The result could hardly have been more effectual if, from the outset, the scheme had been conceived with the deliberate intention of making the removal of the hospital imperative. It remains for the people of Croydon to show that they have more veneration than their rulers.

A large factory has recently been erected in Pixmore Avenue Letchworth, for Messrs. Kinora, Ltd., Photographic Film and Hand Camera Manufacturers. The building is 120ft. long by 110ft. wide, and the front and side walls are built of Fletton bricks, the back being of corrugated iron sheeting, in order to allow of extension at some future time. The brickwork of the front walls is plastered, and is relieved by a base, pilasters, string course, and coping of local red pressed bricks. The roof is divided into five bays of sawtooth pitch, and is formed of steel trusses, supported in the interior of the building on girders and stanchions. The north sides of the bays are glazed with ¼in. patent rolled plate, and the other sides are boarded and tiled. The interior is divided by brick partitions into rooms to suit the requirements of the firm. The steel work was supplied by Messrs. Edward Wood and Co., Manchester. The roof glazing was supplied and fixed by Messrs. Henry Hope and Co., 51, Lionel Street, Birmingham, and the plastering was executed by Mr. J. Coleman, Letchworth. The whole of the other work, including the erection of the steelwork was carried out by the workmen of the First Garden City, Ltd., under the superintendence of Mr. W. G. Satchell, works manager. The factory was designed by Mr. H. Burr, surveyor to the First Garden City, Ltd.

RECENT CHANGES IN BRICKMAKING.

By Alfred B. Searle.

Although it is more than half a century since the first brickmaking machine was introduced in this country, the majority of brickmakers to-day still adopt the old-fashioned method of hand-moulding, which has been passed down from one generation to another for many generations. At the same time the majority of the bricks made in recent years have been produced by machinery.

These apparently contradictory statements are not really so divergent as they appear to be at first sight, as "the majority of brickmakers" include a large number of small yards of very limited local influence, whilst the "majority of bricks" include those produced by some of the yards which are large enough to turn out twenty times as many bricks as some of the smaller works.

The Ancient Simple Method.

It is interesting, on a holiday or other times, in visiting old brickyards, to notice how remarkably small is the change between them and the ancient brickyards of the middle ages. It is only when one is in the neighbourhood of a large town that the progress made during the last fifty years becomes appreciable and the value of the machinery to the brickmaker becomes apparent.

The simplest method of making bricks, and therefore the one most adapted to very small yards, such as are seen in out-of-the-way places, or where the amount of clay to be won is exceedingly limited, is the method of hand-moulding. For this it is usually necessary to have a clay which when dug is of such a nature as to form a suitable paste on mixing it with water in a pug-mill. In the smaller yards this mill is worked by a horse walking in a circular track, in a manner similar to the ancient chaff-cutter. The paste so produced is similar in appearance to mortar, but rather stiffer. It is made into bricks by the moulder taking up a sufficiently large lump and throwing it with great force into a prepared wooden mould, scraping off any excess of clay with a wooden straight-edge, and turning out the contents of the mould on to a board or on to a floor.

The mould is prepared in either of two ways—it may be covered with sand, or it may be dipped in water. The object of the sand and water is to prevent the clay from adhering to the mould when it is desired to turn out the brick

The brick, if placed on a board, is carried by a boy to a barrow or to the drying floor. Formerly, bricks were, as they are to a large extent at the present day, dried out of doors, being arranged in low walls about eight or nine bricks high, the bricks being set very openly. To keep off the rain and to protect them from too direct an action of the sun, they are covered with small gables made of wood, and sideboards or mats are also used to protect them. The more modern method, however, is to dry the bricks by artificial heat, either on a steam or flue-heated floor, or in a series of heated tunnels, through which the bricks are run on special cars. Many patents have been taken out for the use of artificial heat in drying bricks, but even now no arrangement has been found which will be equally satisfactory in all cases.

On the whole, artificial drying is the cheapest, but it requires the outlay of a considerable amount of capital, so that, for this reason alone, many brickmakers are compelled to continue using the less satisfactory method of drying in the open air on hacks.

Hand Pressing.

When bricks of a specially good shape are needed, the hand-made brick must be pressed, usually in a press worked by hand and of a portable pattern, so that it can be taken to different parts of the drying ground, as the bricks must be pressed before they are quite hard.

A method of burning which has been handed down from very early times, and is still used for the manufacture of London stocks, is to use what are known as clamps. These are structures built of the bricks to be burned, the bricks being so arranged that when once the clamp is lit it needs no further attention, but burns steadily on till the firing is complete. The fuel is supplied partly in the form of sifted cinder dust, which is mixed with the clay, and partly from larger cinders (breeze), which is placed in one or more layers in the clamp. When once thoroughly heated by the burning breeze, each brick becomes a sort of fire-ball, on account of the combustible matter it contains, and so needs no attention in the burning. Unfortunately this method is only applicable to certain classes of bricks, and most modern bricks are now burned in kilns.

Early Machinery.

One of the earliest pieces of machinery used for brickmaking consisted in forcing the paste into a mould so as to fill the latter, and then pressing it by means of a descending plunger. This method proved to be very slow, and had many disadvantages which required much ingenuity to overcome; though it was finally discovered that the use of a much stiffer clay paste than that ordinarily used made this process into a commercially satisfactory one, and it is now

used in many yards under the term of the "stiff-plastic process."

Another step forward was made by the use of a horizontal instead of a vertical mixer or pug-mill, driven by mechanical power, which produced a more complete mixture and in much larger quantities than when a horse was used, and it was not long after this that a die was fixed to the mouth of the pug-mill so that the clay issuing from the machine might be in the shape of a number of bricks laid side by side. This clay band is cut into strips of suitable length, and each of these strips is then cut into a number of separate bricks, which are then taken away to be dried. As the cutting is usually done by wire stretched on a frame, this process is commonly known as the wire-cut process, and the bricks as wire-cuts. Such bricks are usually better in shape than simple hand-moulded bricks, but otherwise resemble them in many ways. If the wires are not carefully watched, the bricks will have rough arrises; but the process is so simple, and is capable of turning out so many bricks, that it has become exceedingly popular, though the bricks are not so accurately shaped as those made by the stiff-plastic process, or as others to be described later, in which a press is used and each brick is moulded.

Semi-dry Dry Process.

The addition of water to clay in order to convert it into a plastic paste, and the necessity of removing this water before the brick could be sent to the kiln, have been considered by many people to be a great waste of time and money. A deeper knowledge and a wider experience of most British clays would soon convince them of the error of their judgment in most instances, but there are certain clays which can be worked satisfactorily without first being converted into a paste, and these may be treated by the semi-dry or dry process. These processes are only suitable for certain materials, chiefly of the shale class, in which it is not possible to develop more than a limited amount of plasticity. Such materials are ground to powder, placed in powerful mechanical presses, and formed into bricks which contain so little moisture that they may be taken direct from the machine to the kiln, and the labour of pugging and drying avoided. The best known bricks of this type are those made at Fletton, near Peterborough, but other districts in which suitable materials are found also produce similar bricks, as at Accrington, in Lancashire.

As the clay possesses but little plasticity, it is necessary to use great force in the compression, and in some cases as many as four separate pressures are considered essential to bind the particles firmly together.

Benefits of Machinery.

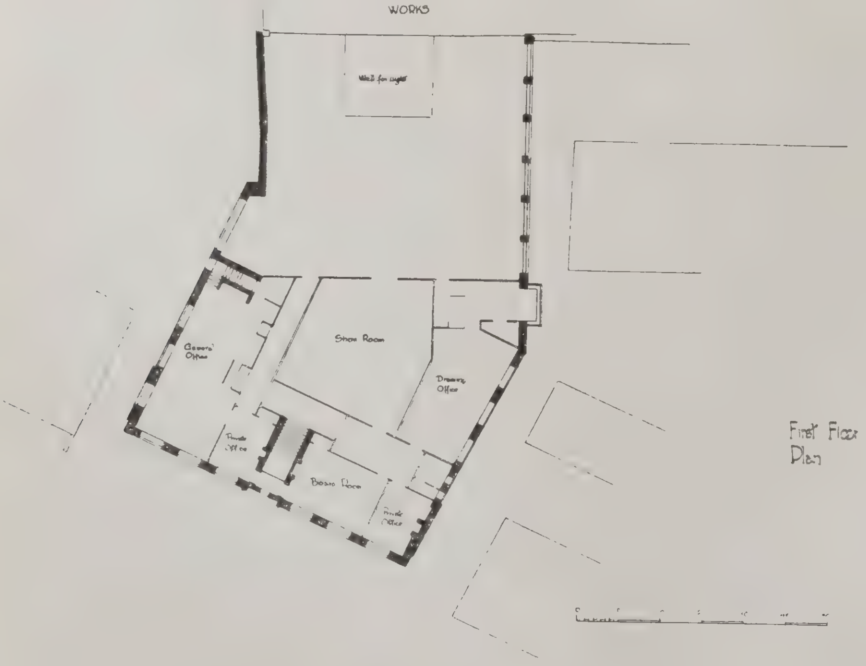
One of the greatest benefits resulting from the introduction of machinery to the brickmaking industry is the much larger range of raw materials which it is now possible to use. Formerly it was only those clays which could be made into a plastic paste with comparatively little trouble that could be employed; but, with modern methods of crushing, grinding and mixing, it is now possible, and in many instances preferable, to use materials which could not be employed before.

The strong plastic clays used for hand brickmaking are always troublesome to dry, and must usually be mixed with some non-plastic material to prevent their shrinking excessively in the kiln. As a plentiful supply of sand or other non-plastic material is seldom found in the neighbourhood of such clays, the sources of suitable material are still further restricted unless machinery is employed. Many shales and other hard materials are really in the nature of clays which have been compressed by natural agencies, and if these can have the effects of the compression destroyed to a sufficient extent to enable good bricks to be made from them, they will often be found to possess distinct advantages over the more plastic clays. It is in the utilisation of these materials that the greatest progress has been made in modern clayworking, and it is in connection with this class of bricks that the greatest changes in the methods of manufacture have been necessary.

Crushing Plant.

No modern brick plant of large capacity would now be considered complete without a crushing plant, consisting of crushing rolls with or without an edge runner mill; and in some cases, where the materials are particularly difficult, as many as three pairs of rolls and two edge runner mills, in addition to the brick-shaping machine, are used.

Yet, although the use of machinery for preparing the clay has brought about great changes in the methods of manufacture, it is probable that the changes in the kilns used have been of equal, if not of greater, importance.



NEW PREMISES FOR MESSRS. DRONSFIELD BROS., OLDHAM. J. HENRY SELLERS, ARCHITECT.

The front of the building is glazed with dull green glazed bricks. The dressings are of polished granite. The whole of the general offices and drawing office are lined with tiles. The private offices and board-rooms are panelled in teak.

Kiln Burning.

Formerly, when kilns were used at all, they consisted of comparatively small chambers heated by a series of fires, the greater part of the heat produced being lost in the chimney. The bricks so made were in many instances baked rather than burned; and yet, in spite of their being what would nowadays be termed under-fired, an average coal consumption of 10cwt. per thousand bricks was considered normal. Now it is thought extravagant to use more than 5cwt. of coal for a thousand bricks, except in very small yards, which cannot avail themselves of modern advantages owing to their limited output. With some shales it is even possible to use less than ½cwt. of fuel!

This great reduction in the cost of burning has been brought about through the introduction into this country of a German kiln, designed by Frederick Hoffmann, in which the heat from one set of bricks was utilised to heat up other sets, and the loss of heat thus reduced to a minimum. Unfortunately, the original Hoffmann kiln was only suitable for the production of common bricks, as the fuel being distributed amongst the goods caused irregular heating and spoiled the colour, unless exceptionally skilled burners were employed. Within the past few years this difficulty of inferior colour has been completely overcome, and bricks of perfect colour, hardness, and strength can now be burned with as little fuel as is generally thought to be possible only with the commonest bircks. The speed at which the burning is conducted has increased with great rapidity of late, though we are still a long way behind some of the German brickmakers in this respect.

Most single kilns require several days to get up to the heat required for finishing the bricks, as the temperature must be raised very gradually or the bricks will twist or crack.

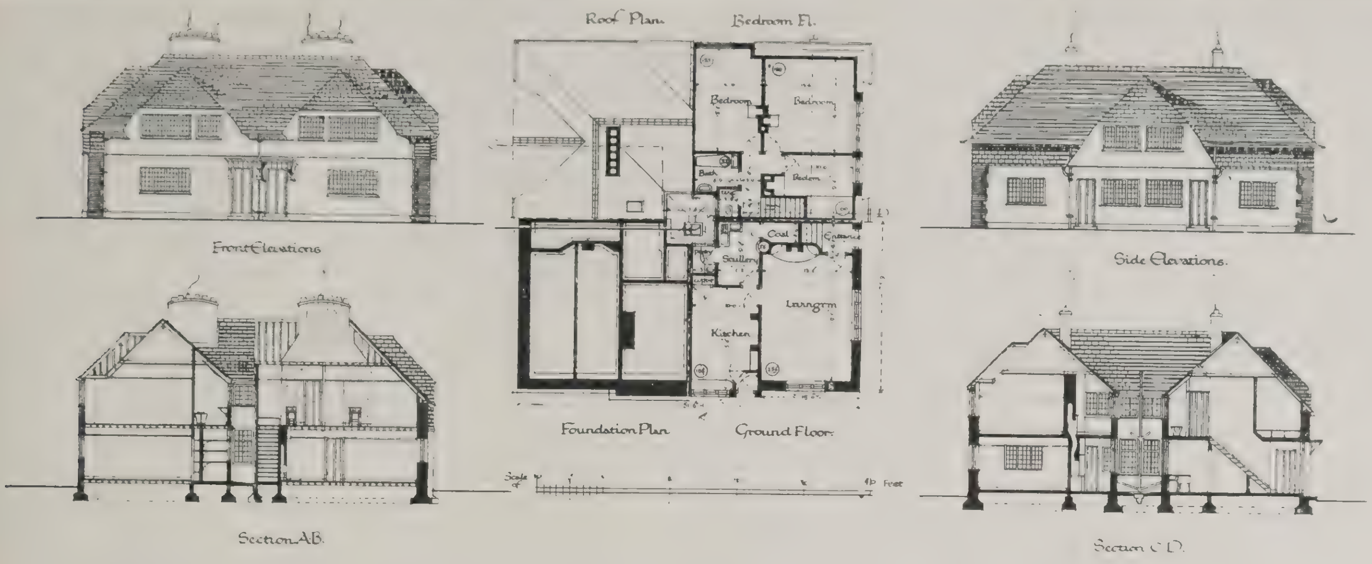
In a continuous kiln they may take almost as long; but the speed of the fire may be increased enormously if proper arrangements are made and the output is sufficiently large. This is possible because in a continuous kiln the bricks are continually being put in and taken out, and the fire travels round and round and never goes out as in a single kiln, the temperature being raised in a perfectly steady and regular manner at any desired rate.

The usual practice amongst British brickmakers is to allow the fire in a continuous kiln to travel at the rate of about 12ft. to 16ft. in twenty-four hours, but this is far slower than need be the case if the kiln is properly designed. Many firms using continuous kilns have not, however, departed noticeably from the original Hoffmann design, except to lengthen the kiln somewhat. By re-arranging the chambers, making them narrower and longer, it is easily possible, with clays that are not too plastic or dense, to allow the fire to travel at the rate of 128ft. per day of twenty-four hours. This wonderful speed is maintained in quite a number of German and Swiss works, but, so far as the writer is aware, only one English yard permits a fire speed of 100ft. per day.

Advantages of Rapid Firing.

So rapid a rate of firing has several advantages besides that of greater output, as the losses by radiation are reduced, and in various other ways fuel is saved and a better class of goods is obtained. At present, unfortunately, it is not possible to produce goods of the best colour at this rapid rate; but as English kiln builders continue to improve their designs, there is but little doubt that within a few years the average speed of kiln firing will be greatly increased. This is the more probable, as it is not difficult to alter many existing kilns so as to secure a more rapid travel of the fire.

The secret lies, as already indicated, in the use of exceedingly long chambers before and behind the bricks under fire, so that the cooling and heating may be carried out



DESIGN FOR A BLOCK OF FOUR COTTAGES ARRANGED AROUND A CENTRAL WELL. ANDREW MUIR, ARCHITECT.

This design is worked out on the idea that a square enclosure is the cheapest to build, and four squares grouped together give the greatest area of ground between groups. The rooms are worked to make the length equal the diagonal of the breadth, and are kept as low as possible. The windows to the well would be obscured, and one pantry would have a French or casement window to give access for cleaning, etc. We invite criticism of this design as to its practicability and saving of space.

steadily. To attempt to increase the speed of travel without altering present kilns would result in failure.

Kiln and Boiler Fans.

The brick chimney has for many years been a useful landmark by which the stranger might identify the works, but the use of fans for producing the necessary draught in kilns and boilers is increasing steadily, and constitutes another recent change in the manufacture of bricks. When a fan is used, the manufacturer finds that he not only has a much better control over the working of his kiln, but that he has a large amount of hot gas available from the boiler furnace, and this can be utilised in various ways for drying, etc. In the ordinary kiln with a chimney, the burner must depend to a large extent on the weather, as in winter the draught is different from that in summer, and a heavy shower of rain greatly diminishes the drawing power of the chimney. All these disadvantages result in an irregular working of the fires in the kiln, and tend to spoil the product or to make its quality less regular than it would be if the draught were under better control. Further than this, the use of fans enables the burner to have plenty of draught at his disposal, and he is therefore able to make more use of hot air and other by-products of his kiln than when he is dependent upon a chimney.

The objections sometimes raised against fans are not so serious as conservative brickmakers often suppose, and a careful and unbiassed study of the subject will clearly show their advantages in many cases, though in certain works where the output is small and the chimney draught ample, no purpose would be served by the introduction of a fan.

Transporting Clay and Bricks.

Nothing is more astonishing to the experienced brickmaker in a country yard than the great changes which have taken place in the means used for transporting clay and bricks. Formerly the wheelbarrow was the chief means employed for moving the clay, and this is still used in small yards and under certain conditions. In the larger yards the barrow has been largely, if not entirely, replaced by small cars or waggons running on a railway track and drawn by horses, ropes, or chains. In a few yards, overhead ropeways are erected, the material being carried in buckets suspended from an overhead rope. This method is particularly convenient when the clay pit is separated from the works by one or more fields or by a river, or where intermediate objects prevent a direct tramline being laid.

Clay Getting.

The manner in which the clay is mined has also undergone a series of remarkable changes during the last quarter of a century. The pick and spade are still used where the clay is of a variable character and needs careful selection, but most yards now use some kind of blasting powder to break down large quantities of material at a time, so that they may be loaded direct into the waggons. In some of the largest brickyards, where the clay deposit admits it, the material is dug by powerful steam excavators, which will dig a ton of material at a single stroke. Where these can be used, the cost of getting the clay is reduced to less than a quarter of its former figure.

In short, the brickmaking business has undergone not one but many revolutionary changes within recent years, those just mentioned by no means exhausting the list.

NOTES ON PAINTING AND DECORATION.

At a recent meeting of the Royal Institute of British Architects, a member appeared to throw cold water on the efforts that are to be made through a section of the Science Committee to produce a standard of quality for materials used in the preparation of paints. Yet the work undertaken is of a most important character, both to architects and their clients.

* * *

Doubtless it will take a great deal of time to investigate all the materials used in paint-making; but if only the most important are dealt with at first, even this approach to the subject will be of very decided advantage. The fact is that architects as a body know less about paints than they do about any other material used in building. It is perhaps natural that this should be so, because practically every other material enters into the construction of the building, whereas paint is added only either to beautify or to preserve. If the concrete, the bricks, or the stone used in a structure are inferior, the fabric suffers from the begining; but if the paint is bad, the only serious consequence is that repainting becomes necessary in a shorter time than would otherwise be the case.

* * *

Many architects appear to think that so long as pure white lead, pure linseed oil, and pure turpentine are used in a paint, they are absolutely safe. But what is pure white lead? It is only a few years since it was decided in a law court that sulphate of lead might properly be sold as white lead, although for centuries hydro-carbonate of lead has always been recognised as white lead proper. And, assuming that the lead is pure hydro-carbonate, it may yet be so coarsely ground as to yield a very bad paint indeed.

It is true that in the case of certain colours such as the lakes, Brunswick green, etc., it would be very difficult indeed to form a standard; but, on the other hand, many colours are quite definite in their composition, as, for example, chrome yellow, which is pure chromate of lead. One might give many similar instances. Then, again, as to linseed oil, there is a wide difference in quality, even among those oils which have not been purposely adulterated. The use here of the word "purposely" needs a little explanation.

* * *

The system of producing the oil by cooking the flax seed, expressing the oil under heavy hydraulic presses, and the subsequent refining, is practically the same at all mills; but in one important particular there may be a vast difference. In a few cases the seed is prepared for crushing just as it comes off the barges, and in not a few instances this seed is small and unripe. In the best mills, however, the seed is screened three times, and it is an "eye-opener" to see the large quantity of dust, dirt, and foreign seed—mustard, hemp, etc.—that is thus extracted. Comparing these two cases, can one say that no standard is required for oil?

* * *

With regard to turpentine, the high prices which prevailed about a year ago caused all sorts of adulterated goods to be put on the market, while it brought about the production of many substitutes, some of which may be used instead of American turps, and are literally "just as good." As a matter of fact, benzine may be employed instead of turpentine without bad effects, excepting for flatted work, when it will be found to evaporate so quickly as to give rise to unsightly laps.

* * *

The Science Committee of the R.I.B.A. have, therefore, in the paint question, a subject which has needed attention for many years past. The hope is that they will not get discouraged because of the immense amount of facts they will be compelled to get together. J.

The Circular Railway, which serves some portions of Berlin and its suburbs, was the scene of a curious accident on August 19th. An iron tower, 280ft. high, situated on the premises of the Imperial Gas Company, at Schöneberg, which are skirted by the line, collapsed just as a train was passing by. A quantity of the wreckage fell on to the last compartment of the train, causing injuries to a number of passengers. None were killed.

In Parliament.

By our Gallery Representative.

Structural Alterations to Burlington House.

Mr. Courthope asked the First Commissioner of Works what was the original cost of Burlington House; and what sums had subsequently been expended on structural and other alterations to this building.

Mr. Harcourt: The total cost of the block of buildings known as Burlington House, now occupied by the Royal Academy, the Learned Societies, and the Civil Service Commission, was £435,212. The trustees are responsible for the cost of all repairs to the portion occupied by the Royal Academy. There has been no charge on public funds on account of structural alterations to the portion occupied by the learned societies. Various alterations were executed for the London University at a cost of £4,051, including fittings, etc., and upon the transfer of that part of the building to the Civil Service Commission the works of adaptation cost £14,016.

An Irish College System Postponed.

Mr. T. W. Russell informed Mr. John O'Donnell that in June, 1907, a sum of £10,000 was provisionally allocated by the Irish Department of Agriculture for the erection of an agricultural college at Athenry. Owing to the unsettled state of the district, action in regard to the expenditure of this money was indefinitely postponed, and the Department were unable to say when, if ever, any portion of the said sum would be expended for the purpose for which it was allocated.

Labour Exchange Buildings.

Mr. Claude Hay desired information from the First Commissioner of Works as to the expenditure of £9,339 for providing buildings under the Labour Exchanges Bill during the next eight months.

Mr. Harcourt replied that the total estimated cost of staff was £7,839, made up as follows:—Professional assistance, including architectural and engineering assistants and draughtsmen, £6,767; technical assistance for furniture, £360; seven second division clerks, £370; four assistant clerks, £170; two female typists, £85; one shorthand writer, £87; total, £7,839. The balance of £1,500, making up the total estimate of £9,339, was in respect of travelling expenses. Mr. Harcourt added, in reply to another question, that it would not be in the public interest to state the items comprised in the sum of £4,500 to be voted for renting buildings, etc., for labour exchanges.

Trafford Park Improvements.

Mr. Joynson-Hicks asked the Chancellor of the Exchequer whether he was aware that about £250,000 had been spent in the preparation of Trafford Park for development, little of which sum would obtain exemption as roads or sewers under Clause 10 of the Finance Bill; and, if so, what steps he proposed to take to prevent such estate incurring the undeveloped land tax, in view of the terms of Clause 10 as now amended. Mr. Hobhouse replied: "I may remind the hon. member that under Clause 14, subsection 4 (a), the Commissioners are to allow, as deductions from the site value of any land, any part of the value which is proved to be directly attributable to works executed for the purpose of improving the value of the land as building land or for any business, trade, or industry other than agriculture." Mr. Joynson-Hicks asked if the hon. gentleman was aware that, according to the amendment made in Clause 10 last week, the exemption was limited to expenditure made within 10 years, and that the bulk of the Trafford Park improvements would not fall within that period. Mr. Hobhouse replied: "No sir, I am not aware of that. I am informed that the deduction which I mentioned under Clause 14 practically relieved the Trafford Park estate of all that of which it is entitled to be relieved."

Building Bills Abandoned.

The "Massacre of the Innocents" announced by the Prime Minister last Friday is fatal to the Buildings and Engineering Works Bill, to the Check-weighing Bill, and to the London Electric Supply Bill. The Government, however, is to proceed with the Housing and Town Planning Bill, the House-letting (Scotland) Bill, and the Electric Lighting Acts Amendment Bill.

The foundations of a villa, indubitably Roman, have been discovered in the marshes adjoining the new Ebbsfleet Pleasure Ground recently opened at Northfleet, and little more than a stone's throw from the confines of the flint field, the treasures of which are not yet exhausted. Already the typical rough red tile pavements have been uncovered, and a quantity of pottery and vases have been discovered, together with a Roman well some 12ft deep. The land is the property of the Associated Portland Cement Manufacturers (Limited), who are excavating chalk there, but to further the cause of antiquarian knowledge the covering earth is being carefully removed by a skilled workman under supervision. The discovery is of great antiquarian interest, as there is every reason to believe that innumerable Roman remains are buried in this part of Kent. The nomenclature of the surrounding district points strongly to extensive settlements of the Ancient Britons and the Danes. Watling Street passes through the woods higher up the hill not more than half a mile distant, and Roman stations are known to have existed at Southfleet and at Springhead. In the time of the Romans a creek, which ran from the river to Swanscombe, was navigable, and this may account for the prevalence of Roman remains, the value of which has been so greatly increased by the discovery of the Roman station or settlement.

BY FRANK B. DUNKERLEY, F.R.I.B.A.

Works in Progress and Completed.

ALBURY.—The church of St. Mary, a very ancient edifice situated on high ground overlooking the valley of the Ash rivulet, has recently been undergoing restoration, the chancel having received the most careful attention. The church is built of flint with stone dressings in the Early English style of Gothic architecture, and probably dates from the earliest part of the thirteenth century. The church consists of chancel, nave, aisles, south porch, and an embattled western tower containing three bells. The sum of £3,000 has been devoted to the work of restoration, which has been carried out under the supervision of an eminent ecclesiastical architect, Mr. W. J. Parker.

ALTRINCHAM.—The new extension of the public baths which were originally designed by Messrs G. Worthington and Sons, of Manchester, was opened recently. The addition has been designed by Mr. Percy L. Lodge, of Manchester, and has been erected at a cost of £4,500. The total cost of the building now amounts to £10,000.

ANNATHILL.—A new school of the central hall type, to accommodate 300 children, has been opened here. Ample room has been allowed for future extension.

ATTERCLIFFE.—The work of restoring the old chapel at Attercliffe with a view to using it as a mission station is now far advanced. All the old features of the ancient structure have been retained, this being specially kept in view by the architect, Mr. Webster. The builders are Messrs. James Fidler and Sons.

BOLTON.—The erection of the new church of St. Philip's, which, including the boundary wall, is estimated to cost £5,000, is now proceeding. The site provides for a church, a school, and a vicarage, and has cost £2,000. Accommodation will be provided for about 550 worshippers in the church, which is the only part of the scheme at present contemplated. The builder is Mr. R. J. Tyson, of this town.

CROMER.—The foundation stone of a new Wesleyan Church to be erected here, has been laid. The church, which will consist of a nave and transepts, is the design of Mr. A. F. Scott. The total cost of the building will approximate £4,000. Mr. Herbert Bullen is the contractor.

DUNDEE.—The new central reading room which is to be erected shortly from the designs of Mr. James Thomson, the city architect, is the gift of Mr. Andrew Carnegie, and will involve a sum of £37,000. The site has been given by Sir William Ogilvy Dalgleish, Bart. The building is in the English Renaissance style, and is crowned by a dome, rising to a height of nearly 100ft., at the base of which sculptured figures representing literature, art, science, and sculpture, are placed. The list of contractors is as follows:—Mason work, D. K. Symington, Dundee; steel work, Fleming Bros., Glasgow; joiner work, John Stewart and Sons, Dundee; painter work, Allan Boath, Dundee; plumber work, J. Farquharson and Sons, Dundee; slater work, Chas. Brand, Dundee; glazier work, Donald and Smith, Dundee; heating, David Keay, Dundee; fittings, Geo. C. Aimer and Son, Dundee; plaster work, Alexander Reoch, Dundee; electric installation, Maxwell, Son, and Co., Dundee.

FLEETWOOD.—The new Empire Theatre and Hippodrome, which was opened recently, is built externally of imitation Carrara marble. The total seating accommodation of the building is 800, of which number, ninety are disposed of by the grand circle. The theatre has been erected according to the plans prepared by Mr. Albert Winstanley, of Manchester, and St. Annes.

HALIFAX.—The new church of St. Hilda's now in course of erection, will accommodate 600 persons, and is to cost £6 484, exclusive of the land, which has been bought for £350. The amount in hand or promised is £4,605 7s., including £1,000 each from Diocesan Societies, Mr. J. T. Ramsden, and the Sanderson Trust, £500 from the Halifax Church Extension Society, and £200 from the Church Building Society.

KESWICK.—A Rochdale cotton spinner has initiated a scheme for the erection of artisan cottages on the garden city plan at Keswick. Tenders have already been accepted for the building of 23 houses, the rents of which will vary from £10 to £25. The scheme will cost £4,000.

LEIGH.—The foundation stone of a new Congregational Church was recently laid. The new buildings, which replace an old iron structure, will cost £5,000.

LONDON.—It is stated that on October 1 the Lord Mayor will open the new Technical College in Tower Bridge Road, which the generosity of the Leathersellers' Company has provided. The college, having a frontage to Tower Bridge Road and backing on to Tanner Street, Bermondsey, commands a most central and convenient position. The freehold has cost nearly £10,000, and the building and equipment of the college will require a similar sum, so that altogether the new Technical College represents a gift of £20,000.

LONDON.—A garage which is being erected by the "Daily Mail," at Wormwood Scrubs, for the purpose of housing the Clement-Bayard airship during its visit to London, is estimated to cost £5,000. The building is to be in perfect readiness by August 30. The builders are Messrs. R. Moreland and Sons, Ltd.

MIRFIELD.—An elementary school, half of which is for babies, and half for infants, was opened recently. Each portion has its central hall, around which are placed the classrooms. The various contracts have been carried out as follows:—Builders, Messrs. John Brown and Sons, Bingley; joiners, Messrs. Halliday and Glew, Queensbury; plasterers, Messrs. Bancroft and Sons, Halifax; plumber, Mr. H. Lindley, Leeds.

NEWPORT.—The erection of a new higher elementary school, designed by Mr. C. F. Ward, the borough architect, is shortly to be commenced.

SANDGATE.—The foundations for the centenary memorial to Sir John Moore at Sandgate are now being put in. The memorial shaft has been quarried, and is being worked with a view to being in position by September 23. The bronze bust of Sir John Moore will be on the side of the monument facing Shorncliffe Camp.

SOUTH SHIELDS.—The infants' department of the Mowbray Council School was opened recently, having cost about £6,800, exclusive of land, furnishing, and professional charges. The department comprises ten classrooms grouped round a central hall, accommodating altogether 600 children. Mr. Henry Grieves, A.R.I.B.A., is the architect, and Messrs. Stephen Sheriff and Sons, of South Shields, are the general contractors. Mr. L. R. Todd has acted as clerk of the works.

Proposed New Works.

ABERDEEN.—At the latest reported meeting of the Plans Committee of Aberdeen Town Council, six sets of plans were submitted, representing work of the aggregate value of £2,500. The plans were for the erection of three dwelling houses, and for sundry alterations and repairs. It is stated that the Episcopalians in the diocese of Aberdeen and Orkney are desirous of establishing a cathedral church, the diocese being the only one in Scotland that is without a cathedral. St. Andrew's, Aberdeen, is favoured as being the most suitable building for the purpose. Certain structural alterations would be necessary, and these would include the removal of the galleries and the extension of the west gable.

ACHNACARRY.—Plans have been prepared by Mr. P. Macgregor Chalmers for a new church which it is proposed to build here in connection with the Church of Scotland.

BARNES, SURREY.—Plans for the following works have been recommended by committee for the approval of the Barnes District Council: lavatory, Mill Lodge, Lonsdale Road, Messrs. Harrods, Ltd.; eleven houses, Martindale, Mortlake, Mr. H. Burridge; sixty-seven houses and two shops, Milton Road, Church Path, and Sheen Lane, Mr. Archibald Stanley; one house, Deanhill Road, Mr. R. B. Rowell; alterations and additions to 339, Upper Richmond Road, Mr. J. Baxter; addition to house, Vicarage Road, Mr. R. B. Rowell; alterations and additions to 40, Station-Road, Mr. Frederick Smith; six flats, Lower Richmond Road, Messrs. E. Beach and Co.; additions to coach-house adjoining Cleveland Hall, Mr. G. W. Smith; seven shops and ten flats, Castelnau, Mr. Arthur W. Osborn.

BLACKBURN.—The congregation of St. Peter's R.C. parish, Mill Hill, Blackburn, have in hand £2,100 towards the erection of a new church which is estimated to cost £6,000, but must raise at least £900 more before building operations can begin, and they hope to realise this amount by means of a bazaar.

BRADFORD. — Three gentlemen — the Lord Mayor of Bradford, Mr. Jacob Moser, and Mr. Joseph Craven, have each given £5,000 to start the fund for the erection of a new infirmary for Bradford, for which purpose an endeavour will be made to raise £100.000.

CLEVELEYS, LANCS.—The new church of St. Andrew, Cleveleys, for which designs have been prepared by Mr. R. H. Cunliffe, of Accrington, is to cost £5,000, and to seat 550. A vicarage and Sunday school are also to be built.

CLYDEBANK.—Warrant has been granted to the City and Provincial Heritable Company, Ltd., Hope-street, Glasgow, to erect seven four-storey tenements of shops and dwelling-houses in Kilbowie Road and Slip-road, Clydebank; also for the erection of a Congregational Church at Radnor Park, and Mr. Walter Kidd was granted permission to erect a double villa in Park Road, Dalmuir.

DUNDEE.—Among the plans that have been recently submitted for the consideration of the City Engineer are those for new centre reading-rooms that the Town Council propose to erect in Ward Road and Barrack Street.

FARNWORTH.—Mr. Lomax has been instructed to proceed with the working plans, specifications, and quantities for the new Carnegie library that is to be erected here at a cost of £5,000.

LOFTUS.—It has been proposed to erect a new school here, at a cost of £3,500, but the ratepayers have held a meeting protesting against the expense. The Council have decided to consider the matter at a special committee meeting.

MORECAMBE.—The Town Council have approved of a scheme for widening the promenade from the Winter Gardens to the West End Pier to a uniform width of 80ft.; to build a new sea wall from a point opposite Highfield to the West End Pier; to double the tramway track in order to afford greater facilities for the working of the system; and to erect new bandstands and construct underground lavatories and shelters. The whole work is estimated to cost £13,000. and is to be put in hand as early as possible, in order that it may be completed for the opening of next season.

NEWPORT, CO. MAYO.—The late Mr. Martin Carey has left £10.000 for the erection of a Roman Catholic Church here.

ROMFORD.—Plans recently approved by the Romford Urban District Council include those for a theatre in the Swan Field, for Mr. T. Cottrell.

STOKE-ON-TRENT.—The question of the extension of the Town Hall has been referred to the Council in committee, the assessor in the recent competition having stated that in his opinion the proposed expenditure of £25,000 on the work was hardly adequate to the requirements.

Notes and News.

There are prospects of better times for the building trade in Dundee. Schedules are issued for the £12,500 contract for the Central Reading Room, and the schedules are to be issued shortly for the £3,000 contract for the construction of the Blackscroft Library. Tenders are also being received for excavations at Caldrum Street Baths. It is also expected the Town Council will be asked to sanction the recommencement of work at Kinghorne Road.

* * *

We are informed that, as from July 31st, 1909, the firms trading as the Imperial Automatic Light, Ltd., the Standard Acetylene Co., Messrs. Hussons, Ltd., the Master Acetylene Co., will trade as Imperial Light, Limited, acetylene engineers, 123, Victoria Street, London, S.W. Departments: Acetylene installations with "Standard" plants; Imperial lights, windproof acetylene flares and hand lamps; oxy-acetylene welding and cutting work, or installations for same, carbide, and purifying materials.

* * *

If the local reporter is to be trusted, a curious performance was given by the gentleman who ceremonially "cut the first sod" for the foundations of a new church at Halifax. "Mr. Taylor was presented with a handsome spade, suitably inscribed, and a barrow, with which he cut the sod and wheeled it away in a decidedly workmanlike manner." Workmen certainly do strange things in the misapplication of implements, but we refuse to concede that it was "decidedly workmanlike" to cut the sod with a barrow.

* * *

The City of London, now that the Traffic Bill has received the Royal assent, has become its own traffic authority, with large powers of dealing with the many problems that beset the subject. Whether it will confine its attention to the relief of congestion by the better regulation of existing routes—that is, by forbidding the obstruction by travellers' broughams, brewers' drays, coal wagons, and costers' barrows—or whether it will also adopt the more heroic treatment that may be roughly indicated as street improvement, remains to be seen. Probably nothing drastic will be done until the fate of the Town Planning Bill is ascertained; but, in any case, the Corporation has now the opportunity of making London what it should be—a model business centre.

* * *

"A Small Owner" writes the following rather strong letter to the "Morning Post:" "Not the least atrocious of the many abominable proposals of the Government is that of taxing brick earth as a mineral. Many a small owner has paid a high price for a few acres of land for the purpose of extracting the brick earth from it and making bricks as a means of livelihood, and to tax him upon his laborious undertaking will be unjust and oppressive. Besides, such a tax must raise the price of bricks and consequently of dwellings. Already it is impossible to build good cottages for farm labourers without putting up with quite unremunerative interest on the outlay, because those men cannot afford to pay rents high enough to render the undertaking an ordinary commercial one, and Mr. Lloyd George proposes, in his reply to Mr. Montgomery, published in your issue of August 18, to render the difficulty of housing the working classes worse than ever."

* * *

The foundations for the centenary memorial to Sir John Moore at Sandgate are now being put in near the coastguard station, on the site of which the hero of Corunna resided while training the troops at Shorncliffe. The memorial shaft has been quarried, and is being worked with a view to its being in position by September 23. The bronze bust by Professor Bonanni will be on the side facing Shorncliffe Camp.

Insurance.

Free £500 Accident Insurance Coupons have this week been sent to the following:

Subscribers to "The Builders' Journal" are entitled to a Free Insurance for £500. Every subscriber should apply for this, sending a postcard with the name of the newsagent with whom the order has been placed. Subscribers can also obtain a General Accident and Sickness Insurance (the "Lighthouse" policy) at a reduced premium, which includes the Annual Subscription to this Journal. A pamphlet giving full particulars can be obtained free on application.

BURDENSOME REGULATIONS.

A draft regulation issued by the Home Office provides that employers shall, for the prevention of lead-poisoning, supply painters and plumbers with soap, nail-brushes, towels, and wash-basins, and that the workman shall use them, and also wear overalls.

The Employer: Now, then, Smith, get off to the job, and don't forget to wash your hands.
The Employed: Right you are, Guvnor. I've got the paraffinalia, but how can I carry the paint?

Secretary:

A. G. WHITE, 31 and 32, Bedford Street, Strand, London, W.C.

MONTHLY OFFICIAL REPORTS.

THE NATIONAL FEDERATION.

There is nothing of consequence to report since the half-yearly meeting in July; all matters arising out of that meeting have been put in hand.

Labour Exchanges.

Matters of importance, however, are coming forward, arising out of the present legislation for the formation of labour exchanges, and in connection therewith the scheme for insurance against unemployment, the building trade being one of the industries scheduled for the application of those measures.

As regards the labour exchanges, the idea is to substitute for the present methods of taking on workmen at the works, shop, or job, the method of applying to the labour exchanges for the number and class of men required. A little consideration will make it apparent that such a change of custom will demand some self-denial on the part of builders and their foremen, who have hitherto had the labour seek them wherever the work was going on, and have been able to select and test workmen until they had secured a fairly efficient manning of their job.

The Board of Trade are, very wisely, consulting representative men among the organised employers and workmen before drafting the regulations under which these exchanges are to be formed, with the object of securing the most simple and practicable arrangements and avoiding pitfalls such as might mar the working of the scheme. As far as possible, full regard will, it is understood, be paid to existing customs in the respective trades, but great tact and much loyal co-operation on the part of both employers and workmen will be needed to bring about so radical a change in the method of taking on workmen.

The regulations will be eventually submitted to the consideration of the various parties affected, and their suggestions considered before final issue.

Unemployment Insurance.

The unemployment insurance scheme will involve a contribution from the employers of our industry equal to perhaps 10s. to 15s. per £100 of wages paid. The idea seems to be that in some way the employers, by supporting the labour exchanges, and so aiding in the better distribution of whatever labour work is going, will be helping materially in keeping down the cost of the insurance against unemployment, and thereby keep down the amount of their own contributions thereto. How this is to be brought about has not yet been made quite clear, but doubtless it will be fully explained when the preliminary conferences with employers take place.

Annual Conference of Secretaries.

The secretaries generally are reminded that the conference of secretaries will take place on October 19th at Leeds, and that the undersigned is very desirous of receiving suggestions for the agenda. So far, very few are to hand.—A. G. WHITE, Secretary.

The Northern Centre.

Secretary: James Denver, Cromwell Buildings, Blackfriars Street, Manchester.

The following is Mr. J. B. Johnson's report to the Northern Centre on the recent negotiations leading to a further amendment of the National Agreement between the "Employers" and the National Association of Operative Plasterers, which, it will be remembered was accepted at the Portsmouth meeting of the National Federation on July 21st.

The first agreement dated 1899, Mr. Johnson states, was drafted and signed at the termination of a national lock-out in that year. Before the lock-out took place, the employers issued a manifesto specifying the points at issue with the N.A.O.P., which may be summarised as follows:—1, the N.A.O.P. require foremen to join union; 2, the N.A.O.P. require limitation of apprentices; 3, the N.A.O.P. boycott certain employers, print and circulate black lists of same; 4, the N.A.O.P. refuse to work with non-unionists; 5, the N.A.O.P. disputes as to demarcation of work; 6, the N.A.O.P. object to submit all trade disputes to a conference with employers before stoppage of work.

Under the first agreement—that of 1899—only two of the points at issue, viz., No. 5, "disputes as to demarcation of work," and No. 3, "blacklisting of employers," were dealt with satisfactorily. No. 2, "limitation of apprentices," was compromised by the employers agreeing that no employer should engage any additional apprentices to the trade while the number of his apprentices exceeded 1 apprentice to 4 journeymen. This arrangement still holds good, and in the new agreement the attention of local committees is directed to see that apprentices do not leave one employer for another in any irregular manner.

No. 1. "Foremen."—This point is now settled upon the following basis—that foremen regularly employed as such shall be at liberty to join the union or not, as they please.

No 4. "Refusal of the operatives to work with non-unionists or defaulters."—Under the new agreement, the operatives have agreed to cancel any objection to work with a defaulter, providing the default has occurred prior to the year 1899.

No. 6.—Under the new agreement, *all trade disputes* are to be submitted to a conference of employers and operatives before any stoppage of work can take place under any pretext whatever. Six days are allowed to locally consider disputes; and in case an agreement is not reached, an appeal can take place to a National Committee, for which ten days are allowed. The committees, both local and national, are to meet at least once a year, and provision is made for rules of procedure on the lines of the National Conciliation Boards in the other branches of the building trades. When the agreement was amended in the year 1904, a new rule was agreed upon, providing that employers were not to be called upon to pay more than the local standard rate of wages to men taken on at a job.

Lancashire, Cheshire and North Wales Federation.

At the annual general meeting of the Lancashire, Cheshire, and North Wales Federation, held in Manchester on June 21st, Mr. William Cooke, jun., plasterer, Preston, was elected president for the ensuing year in succession to Mr. William Bullen, Liverpool.

Before vacating the chair, Mr. W. Bullen, on behalf of the local associations and his colleagues on the administrative committees, presented the retiring hon. treasurer with a gold watch and chain, together with an illuminated address in album form. Mr. Bullen, in making the presentation, spoke in high terms of Mr. Marshall and the services he had rendered the Federation, and, having read the address, handed it to Mr. Marshall, together with the watch and chain.

Mr. Marshall, in reply, expressed the great pleasure it gave him to be with the federated representatives once more; he was not an orator; and to say that he was much obliged was but feebly to express his feelings. Most people were able to buy themselves a watch, but money could not buy the good feeling expressed by that meeting in appreciation of his services. The Federation, he proceeded, had in its early days passed through bad times financially, but he was pleased to see that he left it with a balance of over £1,000 in hand. He was sure the members of the Administrative Committee with whom he had worked so long were doing their utmost for the good of the trade, and he would always bear in pleasant remembrance the many friends he had made during his term of office. Amidst loud applause, he concluded his remarks by thanking all those who had contributed to give him so handsome a present.

Mr. Thomas Meadows, Stockport, was elected senior vice-president, and Mr. Frank Woods, Bolton, junior vice-president. Mr. Thomas Woolfenden, Rochdale, was appointed hon. treasurer.

The other officers and committees were duly elected according to rule.

LIVERPOOL ASSOCIATION.

Secretary: Bertram B. Moss.

The Belgian master builders arrived at Liverpool on August 9th. The visitors, who included sixteen ladies, numbered altogether ninety-six. They left their homes in Antwerp, Brussels, and Ghent on Sunday morning, August 8th, and, travelling by way of Ostend and Dover, reached London the same evening. They did not, however, remain in the metropolis, but came direct to Liverpool, arriving there in the small hours of Monday morning.

The Reception Committee was formed by the Liverpool Master Builders' Association, and consisted of Mr. Frank Griffiths, president; Mr. R. Arthur Costain and Mr. Charles Tomkinson, senior and junior vice-presidents respectively; Mr. R. Stevenson Jones, treasurer; Mr. Bertram B. Moss, secretary; Mr. J. B. Johnson, Mr. N. R. Stirling, Mr. Samuel Fowler; Mr. Otto Heinrich, who acted as honorary interpreter, Councillor John Dawson (Huddersfield), and Mr. A. G. White, secretary of the National Federation of Building Trade Employers of Great Britain and Ireland. These gentlemen, in conjunction with Messrs. Thomas Cook and Son, the tourist agents, arranged a comprehensive programme covering the whole of the day. Notwithstanding that they had only been able to obtain a few hours' sleep, the visitors were ready at half-past nine in the morning for a drive round the city, the gentlemen named, together with Mr. T. D. Alderson and Mr. Miles Mason, Messrs. Cook's representatives, accompanying the party to point out the various places of interest. The route had been selected with a view of embracing all the chief architectural features of the city. Glimpses were obtained in the first instance of St. George's Hall and the magnificent range of municipal buildings in William Brown Street, and then such institutions as the Exchange Buildings, the New Cotton Exchange, the Town Hall, the Queen Victoria Memorial, were passed in review. The drive was continued up Hardman Street and Myrtle Street, where are situate the School for the Blind, the Philharmonic Hall, and the new Children's Infirmary, to Sefton Park. There the party alighted and walked up to the Palm House. On the return to town, a call was made at St. James' Mount, and some time was spent in an inspection of the new Liverpool Cathedral, by permission of the Cathedral Committee and of the contractors, Messrs. R. Morrison and Sons.

For luncheon the visitors were divided into two parties, one sitting down under the presidency of Mr. Griffiths at the Adelphi Hotel, and the other at the Hotel St. George under the chairmanship of Mr. R. Arthur Costain. At each sitting the visitors very cordially pledged the health of the president and members of the Liverpool Master

ROBERT
HALL,
Building Surveyor,
52, Frederick Street, BURY.

With over 35 years practical experience of the Building Trade, and during the last 15 years a very varied experience in measuring up and adjusting contract and other accounts, is prepared to undertake and submit quotations for the following :—

The Measuring-up and Adjustment of Accounts,
Collection and Settlement of Accounts,
Assistance given in Estimating,
Annual or other Periodical Stocktakings,
Private Enquiries and Arbitrations undertaken,
or any other special work incidental to that of a Builder or Contractor.

Builders' Association, their spokesman at the Hotel St. George being Mr. Hesbain, the president of the Antwerp Association.

For the afternoon a trip was arranged on the Overhead Railway to the Canada Dock, where the Celtic was inspected by permission of the White Star Company. On returning the party viewed the new Royal Liver Offices and the new offices of the Dock Board, and then proceeded to the landing stage, and embarked on the Dock Board's steamer Galatea for a cruise on the river. This proved one of the most enjoyable and interesting features of the day's outing, and the visitors expressed their keen appreciation of the courtesy extended to them by the Dock Board in placing the vessel at their disposal. In the evening seats were booked at the second house at the Empire. From Liverpool the visitors proceeded to Sheffield (see the report from the Sheffield Association, given below), and thence they went to London, as recorded in last week's issue.

BARNSLEY ASSOCIATION.

Secretary: J. Denton.

The monthly meeting of Barnsley Association was held at the King's Head Hotel, on Wednesday, August 11th, the president and the senior vice-president (Councillor G. Haigh and Mr. E. Broley), with Councillor W. G. England, J.P., being present at Sheffield in connection with the reception of the Belgian delegates, and the junior vice-president (Mr. C. D. Potter) being confined to his house from injuries received in a trap accident, the chair was taken by Mr. J. Smith, who was supported by twelve members.

A letter was read from Mr. J. Davidson, secretary of the Yorkshire Federation, pointing out certain knotty points with respect to the recent resolution and discussion, at the last monthly meeting, on an alleged infringement of the building bye-laws in the building line of the proposed new tea-rooms at the local park, the report of which Mr. Davidson had read in the BUILDERS' JOURNAL. The tone of the letter was very favourably commented upon, and the definition of the statutory powers of a corporation found general acceptance. Correspondence was also read from Mr. Davidson, calling attention to the National Reserve Fund, and asking for the generous support and loyal co-operation of the various local centres. Mr. T. Lindley having explained to the several new members present the objects of the National Reserve Fund, it was unanimously resolved to lay an equitable levy on each member, and that the amount raised be paid without delay.

A copy of the fair wages clause in contracts, as approved by the National Administrative Committee, was next submitted by the secretary, the general feeling being, however, that the clauses did not apply to the Barnsley district.

An acknowledgment was received from the Town Clerk of Barnsley with respect to the recent letter sent by the Federation on the proposed tea-rooms.

Mr. T. Lindley submitted the report of the Yorkshire monthly meeting, held in Scarborough. He called special attention to the duty of supporting in every possible way the official organ of the Federation, the BUILDERS' JOURNAL, a copy of which was handed round by the secretary for the inspection of the new members. Mr. Lindley laid special stress upon the remarkable value members obtained for their money (apart from official connection). The secretary (Mr. J. Denton) corroborated Mr. T. Lindley's remarks, and added that as the BUILDERS' JOURNAL had been adopted as the official organ of the Federation, it was their bounden duty to subscribe to it.

It was unanimously resolved to call the attention of the Sheffield Association to a case of alleged infraction of the fair wages clause in the form of contract by a Sheffield firm, who were members of that association. The secretary was instructed to write to the secretary of the Sheffield Federation, and also to the contractors in question.

Votes of sympathy were accorded to Mr. C. D. Potter, junior vice-president, and Mr. H. Jacues, secretary of the Operative Joiners' Society, with reference to their recent accidents. It was a remarkable coincidence that both gentlemen are secretaries of the Local Conciliation Board, the former representing the employers, the latter the operatives.

A vote of thanks was unanimously accorded to the acting chairman.

SHEFFIELD ASSOCIATION.

Secretary: Thos. Smith.

The Visit of the Belgian Master Builders to Sheffield.

The Belgian master builders (to the number of 96), who visited Sheffield on August 10th and 11th, will doubtless carry back with them memories of as pleasant and interesting a time as, in the role of hosts, they provided for their Yorkshire friends who visited Belgium last year. The arrangements were in the hands of the Sheffield Association, whose efforts were most heartily supported by representatives of several other associations in the Yorkshire Federation who shared the Belgian hospitality last year.

The visitors reached Sheffield early on Tuesday morning from Liverpool, where they had been entertained by the Liverpool association, and were met at the station by representatives of the Sheffield Association, including the president (Mr. W. W. Mears) and Messrs. A. J. Forsdike, J. Biggin, J. D. Cook, T. Eshelby, W. Longden, J. Wilkinson, and T. Smith (secretary), together with the Belgian Consul (Mr. Schott) and Mrs. A. J. Forsdike and Mrs. W. Longden. After a hasty visit to their respective hotels they were taken to the Town Hall, where they were received by the Deputy Lord Mayor, Ald. H. P. Marsh, who gave them a hearty welcome to the city. The Lord Mayor, who was unavoidably absent, provided refreshments, and, in company with the municipal officials, the visitors made a tour of the Town Hall. Thence they were taken to the extensive electro-plate works of Messrs. Walker and Hall. At 1.30 the party found themselves at the Builders' Exchange, where a lunch had been provided to which about 130 persons sat down. Here the president (Mr. W. W. Mears) formally welcomed the visitors. It would be difficult, he said, to equal the welcome with which the Yorkshire builders were received in Belgium last year, but the Yorkshiremen were, on the present occasion, determined to do their best. One matter only cast a shadow on their gathering, and that was the remembrance that the esteemed Burgomaster of Antwerp, who received the Yorkshire builders so hospitably last year, had passed away. The president could assure our Belgian guests that the English builders shared their grief at the loss of a gentleman who occupied such an exalted position and was so intimately connected with their association.

Mr. Hesbain (president of the Antwerp Association) replied in English, and Mr. Van Autryve (president of the Ghent Association) spoke with much enthusiasm in Flemish, his speech being subsequently translated by Mr. Hoffmann, and loudly applauded. Further speeches were given alternately in English, French. and Flemish, amid scenes of much enthusiasm.

After lunch the visitors were shown over the cutlery works of Messrs. Joseph Rodgers and Sons, Ltd.

In the evening the visitors were entertained to dinner at the Royal Victoria Hotel, at which nearly 160 persons were present.

The president (Mr. W. W. Mears) was in the chair, and was supported by Colonel Sir John Bingham, the Mayor of Barnsley (Ald. Rideal), the Mayor of Rotherham (Councillor D. Mullins), Mr. J. S. Rose (Deputy Mayor of Barnsley), Councillor Fenton, Mr. R. M. Prescott (Town Clerk), Mr. F. E. P. Edwards (City Architect), Mr. Hadfield (City Road Surveyor), and Messrs. J. Biggin, A. J. Forsdike, J. D. Cook, T. Eshelby, W. Longden, T. Roper (Sheffield), Mr. A. W. Sinclair (Scarborough), Mr. R. Schott (Belgian Consul), Councillor J. Daw-

son (Huddersfield), Mr. J. Davidson (secretary Yorks. Federation), Councillor England (Barnsley), Mr. E. M. Gibbs and Mr. T. Smith (secretary). Amongst the Belgian guests were Mr. A. Hesbain (president of Antwerp Association), Mr. V. Merckx (president of Antwerp Conciliation Board), Mr. Vandewren (V.P. Brussels Association), Mr. Van Autryve (president Ghent Association), Messrs. A. Grangé and F. Van Dyck (secretaries of Antwerp Association), Mr. E. Opdebeeck (president of Excursion Committee), and Mr. F. Staadt (treasurer of Brussels Association).

The toast list was printed in both English and French for the convenience of the visitors, and the menu was a fine example of the printers' art, and was much in demand by the visitors as a souvenir of the occasion. On the front appeared the English and Belgian flags in colours interlaced, while in the centre three panels carried the portraits of the respective presidents of Sheffield, Brussels, and Antwerp.

The loyal toast having been duly honoured, Mr. Biggin proposed "La Belgique et Son Roi;" and took occasion to refer to the fraternal feeling which existed between the English and Belgian builders, a feeling which he knew was also shared by the people of both countries. They had very happy memories of the reception which was accorded them in Belgium last year, and they desired to reciprocate it in every way possible.

Councillor Dawson, in proposing "Les Entrepreneurs Belges," spoke in his characteristically happy vein, and his speech having been translated into Flemish by Mr. Hoffmann,

Mr. Hesbain (vice-president of the Belgian National Federation), replying in English, thanked them for the sympathetic reference which had been made to Belgium and to their King, whom they called in Belgium the King of the Builders. He had been told that a characteristic of Sheffield was its welcome to strangers, and their experience had confirmed this. Since they made the acquaintance of the Sheffield builders last year, they had urged them time after time to pay a return visit, and had even sent delegates to convey their invitation. They had no doubt that they would be received with open arms, but they were bound to confess that they never expected such a brilliant reception as that which had been given them. Their Sheffield friends had overwhelmed them with their marks of friendship and sympathy. He hoped that their gathering would promote more and more the co-operation of the builders of all nations, an object which was being most persistently pursued by Mr. Van Ophem (Brussels), who they regretted was unavoidably absent. At present, however, it was encouraging to note that the International Federation comprised 15 nations (including the English), and nearly 20,000 members. Between England and Belgium there had existed for centuries a mutual friendship founded on the same love of political and individual liberty and respect of the traditions of their forefathers.

Mr. Vandewren (speaking in French) referred to the happy results which were following the initiative of the Sheffield Association last year. They said in Belgium that union was force, and their international union could not but be productive of the greatest good.

Mr. Van Autryve also spoke in Flemish in a similar strain.

"The City and International Trade of Sheffield" was proposed by Mr. A. J. Forsdike, who regretted that the shortness of the visit did not permit them to show their guests more of the "Steel Metropolis." He hoped that they would carry back happy memories of their visit.

Colonel Sir John Bingham, replying in French, thanked the guests for the honour they had done to Sheffield by visiting it.

Mr. J. D. Cook proposed the toast of "The Visitors," to which the Mayor of Rotherham and the Town Clerk of Sheffield responded.

Wednesday saw the visitors astir early, and at 9.30 they left in special trams for the works of Messrs. Vickers, Sons and Maxim, where they were shown over these extensive works, and witnessed the rolling of an armour plate, and the forging of a large gun.

Lunch was again provided at the Builders' Exchange, and at 2 o'clock the party, whose numbers had now been swelled to more than 180, left in carriages for a drive through some of the prettiest Derbyshire scenery to Chatsworth House and park, and afterwards drove on to Grindleford, where tea was provided, Sheffield being reached by various sections of the party between 10 and 11 p.m.

On the visitors leaving Sheffield for London, on the Thursday morning, a pretty little ceremony took place on the platform, where the Belgian party presented beautiful bouquets to Mrs. W. W. Mears, Mrs. A. J. Forsdike, and Mrs. T. Smith.

On Sunday the following telegram, addressed from Dover pier, was received by the president (Mr. W. W. Mears): "Before leaving England, the Belgian master builders wish to send to your association their brotherly salute, with the expression of their feelings of gratitude for your kind reception, which they will remember for ever.—Hesbain."

CONCRETE PIPE FOR WATER UNDER HIGH PRESSURE.

Concrete pipes, reinforced with steel, have been used for several years by the United States Government in its various reclamation projects in the West. Until recently, however, some doubt remained in the minds of the department engineers as to the feasibility of transmitting water under pressure through pipes of reinforced concrete.

With a view to determine as nearly as possible the water pressure which properly made concrete pipes are capable of withstanding, the reclamation service engineers have been conducting a series of tests near Portland, Ore. The tests are not yet completed, and the ultimate results cannot be accurately foreseen, but hitherto the concrete pipes have withstood higher pressure than was expected, and have demonstrated their value in much of the work of the department in which more expensive steel pipe have hitherto been used.

Supervising Engineer E. G. Hopson, Portland, Ore, reports that the tests have been so satisfactory that the Government is proceeding with the manufacture of reinforced concrete pipes for carrying pressure currents of water on several of the projects in hand in his territory. He says that the interior diameter of the pipe tested is 46ins. and the thickness of the shell 3ins. The concrete was made of one part Portland cement, 1½ parts sand, and 2 parts gravel. Reinforcement consisted of specially wound 5-16in. wire which was subjected to strains in tension of 12,000lbs. to the square inch of metal.

The pipes were subjected to pressures up to 60lbs. to the square inch and successfully withstood all pressures applied. The water was forced into the pipes by means of a gasoline pump, which, unfortunately, could not deliver water under a pressure greater than 60lb. to the square inch. Under the high pressure, water exuded through the pipe in insignificant quantities. This action, is was shown, will cease after the pipes have been in service a few days.

A quantity of reinforced concrete pipes now in use on different projects has been found to be economical and satisfactory. Pipes had not hitherto been subjected to so high a pressure as the above, and the object of these tests is to demonstrate whether it would be safe to use it for pressures exceeding 100ft. head. The tests already made have proved so satisfactory as to warrant the manufacture of these pipes in large quantities.

Technical Journals, Ltd.,
CAXTON HOUSE, WESTMINSTER, S.W

"We have an excellent opening which I should like to offer you as one of our own men. The only question is: Do you possess the necessary technical training?"

What answer could YOU make if you were approached by your employer as shown in the picture above?

A man cannot fairly complain of not securing advancement if he fails to prepare himself to take advantage of his opportunities.

Determine *to-day* to get the training which will enable you to embrace every opportunity—to succeed in a high grade position—to command a good salary.

You can readily get this training—without interfering with your present work, without the inconvenience of attending classes, and without embarrassing yourself financially, through the International Correspondence Schools, which exist for the one purpose of preparing ambitious men, by home correspondence study, for better posts.

Leading employers recommend our courses as of definite money value, and our students are continually reporting how their studies have marked them out for promotion. Here is just one instance:—

> "Barrow-in-Furness.
>
> Referring to my progress, I may say that my employer seemed to take a great interest in the Schools and often came to enquire how I was proceeding with my studies, and when you wrote to him of my progress in your School of Mechanical Engineering he came straight to me and congratulated me. Of course, that made me try all the harder, and it certainly has done a great deal towards my getting transferred to a higher standard of work; it is considered a great honour here to be put where I am before five years are up. The report that you sent Mr. .... was instrumental in securing me the better position. (Signed) WILFRED J. HOLMAN."

"OUR STUDENTS' AID DEPARTMENT"

which is in close touch with employers in every district, devotes its entire attention to assisting I.C.S. students in the matter of employment by recommendations to present employers (when desired), information as to vacancies, introductions, etc.

Don't condemn yourself to poor pay all your life. Mark the coupon, or write us about any special career, and ask about our "Students' Aid Department"—NOW,

86

POST FREE, 12s. 6d.

Prof. C. H. REILLY, of Liverpool University, says: "I think it is a very valuable book, and I hope it will find its way into most architectural offices."

THE "PRACTICAL NOTES" gives in most convenient form for use on the drawing board examples with concise rules, explanations and dimensions for preparing Designs, Perspectives and Working Drawings for Classical Architecture with rapidity and precision.

STUDENTS preparing for the examinations of the R.I.B.A. can learn how to draw The Orders correctly with the smallest possible amount of study and work by utilising the invaluable drawings and data given in this publication.

We shall be pleased to forward a copy of this work on approval to any of our subscribers.

Builders' Locked-up Capital. A notorious evil that has long operated with ruinous effect in the building trade is illustrated with almost dramatic force in the instance of a Northern firm who have just voluntarily "filed their petition." This firm, which is of long and honourable standing (it was founded in 1848, is paying something like £2,000 a week in wages, and has occasionally paid as much as £6,000 a week), has been led to take this course for the simple reason that clients are in its debt to the very pretty tune of £80,000—actually eighty thousand pounds sterling! This thumping sum is said to be "locked up" in buildings for which payment has been unduly delayed. This current instance of the evil may be exceptional in its magnitude, but it is not otherwise extraordinary. Unhappily, financial failures among builders who would be perfectly solvent and prosperous if only they could come by their own are too frequent and familiar to excite much attention. They have come to be regarded as commonplace and customary trade incidents. Any fatalistic and spiritless submission to unfairness, however, is to be strongly deprecated. It simply aggravates and encourages an evil that ought never to have been tolerated by the trade. It has been allowed to grow to monstrous proportions because of the former lack of unity among builders, who in the old days could be more easily played off one against another than is possible now that the members of the trade have been wise enough to organise for mutual protection. It is only by concerted action that this distressing evil can be mitigated; and certainly whatever steps are possible should be promptly taken to arouse the public conscience in the matter of unreasonably and unjustly delayed settlements. United action and a determined front may bring a welcome relief from at least the worst horrors (the term is surely not extravagant, when we recall the undoubted fact that from this cause honest men have been harassed into untimely graves) of this curse of the trade. Insurance against bad debts and against deferred settlement of accounts has been suggested as a palliative; but the knowledge of such resources would simply harden the heart of the unscrupulous client. An aggressive assertion of right and justice would certainly be more dignified and would probably be more efficacious. Doubtless all commerce and industry are founded on a well-ordered system of credit; but the grave abuse of the system on "Kathleen Mavourneen" lines—"It may be for years, and it may be for ever"—should be discountenanced and discouraged in every possible way. The ordinary owner is apt to be "long-winded" enough; but it is amongst the millowners of the North that the vice is most rampant. They have reduced deserment to a fine art. In this quarter, we are credibly informed, failure to pay up within a reasonable time is habitual and systematic. The builder erects a mill; for years the owner refrains from paying for it, and is all the while making in reality a free exploitation of the builder's capital. The £80,000 belonging to the firm that has been impelled to file its petition is, it may be supposed, only unproductive in the case of the persons who by every moral right are entitled to the interest on it. It is those among whom it is distributed, by whom it is withheld, and to whom it does not belong, who presumably are realising more or less handsome profits out of it. Of course the evil of long credit does not end here. A long train of ill consequences may ensue upon the initial default. The builder whose clients are tardy in settlement may possibly be himself compelled to get into debt, to lose the discounts and other advantages of prompt payment, and even to borrow at heavy interest. Surely the whole question is one that the National Federation of Master Builders should immediately take into most earnest consideration—a course from which they should by no means be deterred by contemplation of the difficulties with which the subject is but too obviously beset.

Art an Instinct. At a Dutch symposium, it is or used to be the custom for everybody to smoke so prodigiously as to produce an all-obscuring reek; insomuch that, in order to rescue a man's countenance from mere oblivion, it was necessary to blow upon him with a pair of bellows. Even so has it seemed good to clear away the obfuscation from the fair countenance of Art; and the man with the bellows is a leader-writer in the "Times." He has repeatedly rendered this service; and he was never more successful in the dispersal of obscuration than when, in an article on "The Importance of Art," he lustily blew upon the strange misconceptions with which nowadays the issue is apt to be rather effectually obscured. Mr. A. B. Walkley, in his evidence before the Dramatic Censorship Committee, had said that in his opinion the importance of all art was apt to be overrated nowadays, and that we take such things a little too solemnly. The critic does not smite and confound Mr. Walkley, but expounds his meaning, which probably was that the art which strains after the expression of new ideas seems to its devotees to be of more importance than it is: "They are apt to suppose that all art is a mystery only to be understood by a few of the initiated, and even that the narrower the appeal the greater must be the art." The very sensible comment upon this misconception is that "If this were true, then indeed art would be a thing of small importance to the life of man; for only the few who have leisure enough to spend much of their time in cultivating themselves could get any good from it, and the good which they got from it would not be very evident to the rest of the world." This fallacy, the writer declares, could only have grown up in an age with little understanding of the nature of art and of its real importance. The masterpieces of art—in music, poetry, or painting—can only be produced as the result of centuries of popular art. "The master, and the technique of the master, are only possible after generations of obscure and humble effort, which would never have been made unless there had been a popular demand for it." The great masterpieces of art "are what remain to us from the wreckage of the past." Whistler's conception of them as springing into being by a sort of miraculous chance was shallow and unscientific, if not wholly fallacious. Clearly he had but little patience with the theory of evolution, although he would probably have yielded a conditional assent to the critic's proposition that "there must be something wrong with a society which fails in something which men have always tried to do and which gives innocent pleasure when it is well done." This follows upon a statement—which none dare dispute—that "so strong is the instinct of man to ornament everything connected with his daily life that if he cannot devise good ornament he will always devise bad," and that "that is the artistic instinct which not even the nineteenth century has been able to suppress, and which therefore we may assume to be, like love, as strong as death." The instinct—one is very doubtful about the legitimacy of the word, but it would perhaps be difficult to find a more appropriate substitute—is all too easily perverted; but, contrariwise, it should be easily susceptible to right cultivation. It can be trained to noble uses. Hence, as William Morris recognised in the substance and in the title of his famous lectures, we are perennially beset with "Hopes and Fears for Art;" and if we are wise and of good courage, the hopes shall predominate and prevail. To this end the man with the bellows is helping us mightily. By the vigorous and persistent application of his homely but effective implement, he is creating for us, if not a perfectly clear atmosphere, at least a sort of chiaroscuro, in which the true forms and lineaments of things become more clearly defined and more certainly discerned and recognised.

An Abortive Building Code. The New York building code is ten years old. It is therefore, as codes go—especially in swiftly moving America—a hoary antiquity. Building practice has got a long way beyond it, and £40,000 has been spent in revising it. Yet the resultant new code has been rejected, mainly because it was polluted with what a newspaper writer euphemistically calls "politics." What he means by this expression is made pretty clear when he adds the explanation that the proposed new code, "while excellent in many of its provisions, contained certain stipulations and restrictions that would have caused serious disadvantage to the community, although pecuniarily profitable to the interests responsible for their enactment." The axe-grinders, it appears, were defeated by "the energetic and reasonable opposition made by engineers, architects, and building contractors," who objected to the favouring of certain brands of building materials and equipment. The point around which contention raged most fiercely was a pronounced preference for brick and tile fireproofing to the disadvantage of concrete. This unfairness was fatal to the code, which, however, was excellent in the parts that were not infected by the deadly virus of "politics," as it provided for the examination and registration of engineers, architects, and builders, and stipulated for more efficient means of protection against fire and of preserving the public health. It would appear that the code had to be accepted or rejected holus-bolus; or, at all events, it does not seem to have occurred to the New Yorkers to adopt the advice of Hamlet to his mother, and "throw away the baser part and live the better with the other." Indeed, for some reason of which we in this country are happily not in a position to fathom the darksome depths, such a course would seem to be quite impraticable in the peculiar circumstances of American public life; for it is added that it is doubtful whether the good points "can be inserted in the next revision, whenever it may be made, without considerable opposition." All this is very, very sad; but any pharisaic impulse to enlarge on the superiority of our own public wisdom and morality should be repressed with careful artistic restraint. It might provoke reprisals; for the conflict between public and private interests is probably universal and sempiternal, although the methods of pursuing it are apt to differ with the country and with the diversities of national temperament. But we are nevertheless heartily glad to learn that the American engineers, architects, and builders are on the side of the angels, and, with their aid, possess sufficient dynamic force to defeat the hosts of darkness.

The Whitgift Almshouses. In another part of the present issue we print an article in which Mr. S. W. Kershaw, F.S.A., presents some interesting particulars relative to the inception and building of Whitgift's Hospital at Croydon. Together with other curious data, it is shown what the materials are, whence they came, and, in some instances, what they cost. In this account it is shown how completely the Hospital fulfils the crucial condition that modern purists have of late years persistently imposed: it is indigenous to Croydon. This was, of course, a foregone conclusion, seeing the age of the building; for although doughty deeds were done in the spacious and strenuous days of great Elizabeth, the means of conveyance and the state of the roads forbade the carrying of building materials over great distances. The fact that the Whitgift Hospital sprang as it were from the earth on which it stands is one reason why it looks so much more at home than the modern buildings which in its native simplicity it puts to shame. Of course it cannot be helped that most of our wood, much of our glass, and some of our slates are nowadays brought overseas from far countries. Nevertheless, the people of Croydon may excusably take pride and pleasure in the knowledge, to which we are happy in drawing attention, that this venerable and beautiful building is racy of the soil, a true creature of its natural environment, thoroughly English and completely Croydonian; and this consideration ought surely to make an irresistible appeal to local sentiment and patriotism, even if the artistic merits and historical association of the building were deemed to be an insufficient warrant for its preservation. We are happy in the assurance, which is given on the authority of an obviously inspired announcement in the "Times," that the Local Government Board will absolutely refuse to sanction the demolition of the Whitgift Hospital.

Town Hall Trials and Troubles. The selected plans for Burslem Town Hall are criticised at considerable length and with somewhat caustic severity by an anonymous correspondent of the "Staffordshire Sentinel," who complains that the assembly hall is not large enough, that supper-rooms, lounge, reception, card and entertaining rooms have not been provided, that the concert-hall is similarly ascetic, and so forth. He adds, "I cannot blame the assessor," because the printed conditions "merely require certain rooms, without indicating how these rooms are to be used." That the conditions of architectural competitions are seldom or never satisfactorily drafted, is an old story; the successful design that pleased everybody would be an amazing novelty. Still, as the correspondent remarks, the object of exhibiting the designs is presumably "to invite the criticism of the ratepayers who will be called upon to find the money," and who are proverbially entitled to "take it out in grumbling." By the way, is it quite fair to architecture for the ratepayers to make their town hall (there is here no special reference to Burslem) such a jumble of heterogeneous interests? Many of them are required to be of such mongrel constitution as to recall the famous compromise illustrated by Mr. J. F. Sullivan in a series of his inimitable drawings on "The British Working Man: by One Who Does Not Believe In Him." The client wanted a summerhouse built. The workman he consulted suggested that a pig-sty would be more profitable. The client pleaded even unto tears for a summerhouse. The workman's stony heart was so far affected that he resorted to a generous and an ingenious compromise. The resultant structure was so cleverly arranged in a Composite style, that it could be used either as a summerhouse or as a pig-sty, or as both, and nobody could tell from merely looking at it which it was really intended to be. If some of our modern muddled town halls do not exhibit a similar lack of definite character, it is because the architects have shown singular adroitness in reconciling diverse features that are mutually and almost hopelessly antagonistic. But the municipal appetite for this sort of mixed pickles seems to be general and insatiable.

Early London Theatres. In an announcement to the effect that Sir H. Beerbohm Tree has been invited to unveil a commemorative tablet marking the site—on one of the buildings appertaining to Messrs. Barclay and Perkins's Brewery, Bankside — of Shakespeare's Globe Theatre, the reporter has been betrayed, by the exuberance of his enthusiasm, into an egregious error. He claims that the Globe was probably the first theatre built in the Metropolis. Of course it was nothing of the kind. In fact, it was actually constructed of the materials of a theatre that had been in existence for more than twenty years at Finsbury. And thereby hangs a tale, which, founded on the actual facts, has been well told, if we remember rightly, by Mr. A. T. Quiller-Couch, in "Shakespeare's Christmas," with the addition of a good deal of handsome imaginative embroidery. It is told more convincingly if less artistically by Mr. T. Fairman Ordish, F.S.A., in his excellent "Early London Theatres." The Theatre, as it is called, was built in 1576, for the Burbages, on ground belonging to one Giles Allen, who, when the lease had expired, wanted to assume the ownership of the building. The Burbages and their friends, including Shakespeare, formed an armed party, who, in spite of protest and active opposition, demolished the Theatre, and conveyed the materials to Bankside, where they built the Globe. The party, in the words of Allen's Bill of Complaint against Cuthbert Burbage, "did then alsoe in most forcible and ryotous manner take and carrye awaye from thence all the wood and timber thereof unto the Banckside in the parishe of St. Marye Overyes, and there erected a newe playhowse with the sayde timber and wood." As to its materials, therefore, the Globe lends colour to the reporter's light-hearted assumption of priority; but as a structure it was junior to perhaps more than half-a-dozen other theatres. Its claim to commemoration is its association with Shakespeare, who was one of its proprietors, and with Ben Jonson and other great lights of the Elizabethan drama.

THE BUILDING OF WHITGIFT'S HOSPITAL.

By S. W. Kershaw, F.S.A.

In the County of Surrey are two hospitals for the poor, one at Guildford, founded by Archbishop Abbot, a native of that town, and another at Croydon, erected by John Whitgift. Such charitable institutions would seem to be the successors of those earlier structures in our land, which were used by travellers, pilgrims, or the monastic orders, in the 14th and 15th centuries, to whom they offered a refuge and hospitality. In the sister County of Kent, we find good examples of these buildings, of St. Bartholomew's Hospital at Sandwich, Eastbridge and St. John's at Canterbury, and another at Habledown. At Angers, the hospital of St. Jean, built by our Henry the Second, is almost perfect, and one of the treasures of 12th and 13th century domestic work in that city of artistic and antiquarian wealth.

The building accounts of Whitgift's Hospital reveal minute particulars of the care in the development of the building, which occupied three years. The first stone was laid February, 1596, and the building was finished September, 1599, the payments and charges were inspected weekly by Samuel Finch, Vicar of Croydon, and alterations, made from time to time by the Archbishop. The materials were all obtained from the locality, and the total expense was £2,716 11s. 11d., a large sum in those days. The bricks, lime and mortar were made near Croydon, the timber and stone also from the county, while the downs around the town afforded the chalk material, which was converted into lime and cement. The great Wealden forest of Sussex stretched into the Surrey border, while Norwood or the Northwood, dense in timber and underwood, surrounded Croydon on its London-ward side. Lingfield seems to have supplied much of the timber for the hospital, as appears from an entry in the accounts.

"There is hewed at Lingfield 27 loads of timber and a half at xvj's the load."

"For the carriage of four loads from Lingfield to the hospital at xj per load."

Nearer home from a wood called Dragnells, the name probably surviving in Dagnall's Park, near Selhurst, "xix loads of wood were obtained and used for the kiln at xiiij'd per load."

This item would be for kiln faggots that were employed for fuel, in the burning and mixture of the lime and chalk.

Wood might also have been obtained from the Archbishop's park, an appanage to the old Palace at Croydon; this park no longer exists—in past times, a keeper was regularly appointed; the name of the park survives in Park Hill, long ago modernized by suburban villas.

The stone for the hospital was found in the quarries of fire stone, extending from Reigate to Limpsfield northwards to Merstham; it was chiefly used for the details, as appears from the building accounts, "so much good and seasoned free-stone as shall be sufficient for the doors and windows."

The Surrey historians, Manning and Bray, mention a quarry at Godstone, where a sort of freestone was obtained, and "was made into window sills and coping stones of walls and sent to London." Great care was taken in laying the foundations of the hospital, "flint and chalk was provided for the building, and small for filling, because the lower ground is not so good and firm as the upper, and the weight of the work may not be trusted only on brick." It appears some of the stone was brought from Southwark, according to another entry, "paid for carriage of loads of hard stone from Southwark to the hospital."

This statement would refer to landing the stone at Southwark, in those days, river transit was the ordinary method, and Reigate stone which was used for building of the old Westminster Palace and for additions to Windsor Castle would have been sent by water and landed on the Thames bank.

Of the famous Nonsuch Palace, built by Henry the Eighth, portions were of Reigate stone.

The work at Whitgift's Hospital went on systematically, in a thorough manner, the two corner stones were laid by the Archbishop in March, 1596, and in June of that year "the first of all the hospital was reared." In 1597 all the outwork as tiling was finished, and in 1598 the seats in the Chapel were finished, and the Chapel paved and the door hinged in 1599. On the 9th of July, 1599, the hospital was dedicated to the use of the poor by Bishop Bancroft (London), and Anthony Watson, Bishop of Chichester, the seal of the foundation was that of Dires and Lazarus, and the statutes were framed by the Archbishop. The inmates who need relief not to exceed 40 in number, to be chosen by the Archbishop and his successors, from those employed at Lambeth and around, also from Croydon, and from some Kentish parishes.

Gardens and orchards once surrounded the hospital, but the pressure of building extension has much curtailed these grounds. The interior of the hospital is rich in carved and panelled work as seen in the hall and other rooms. The quadrangle affords an excellent view of the building, mellowed by the old brickwork, and picturesque in the trim flower beds around, somewhat recalling the college enclosures at Cambridge.

The little chapel in the corner of the quadrangle contains some old glass. The fittings and seats of the chapel were made of knotted timber, and the fine oak wainscot was put up about 1640.

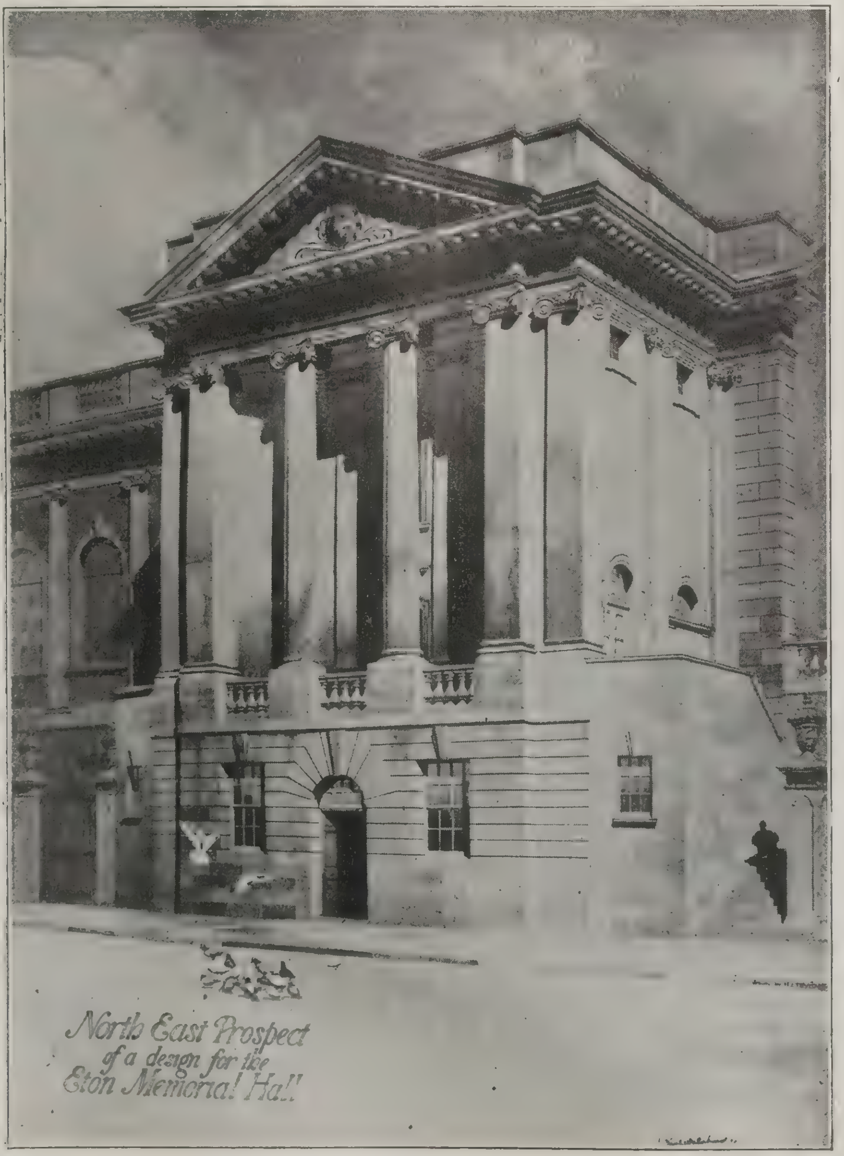
The Hall (where the inmates dine) claims special notice, being in the same condition as when the Archbishop used to dine with what he called "his poor brothers and sisters."

Here is some old glass with the arms of Queen Elizabeth, oaken tables, and on the mantel a block of black stone, part of the Archbishop's tomb (destroyed) in the Parish Church, which was almost entirely burnt in the fire of 1867. Other fine monuments perished, and were broken beyond repair, especially that of Archbishop Sheldon. The Whitgift monument was most ably reproduced by the help of old drawings and the skill of Mr. John O. Scott, F.S.A., architect. The recumbent figure of the Archbishop is surmounted by Renaissance work, with sculptural details, the black and white marble forming a charming contrast to the general setting.

In the large room of the hospital over the gate-house (now the warden's room) Dr. Whitgift used to entertain his friends, the Earl of Shrewsbury, Lord Zouche and Bishop Bancroft—in this room is some fine panelling, a carved mantel with the arms of the founder, stained glass, an ancient chest, and some rare Mazer bowls.

Thus the Hospital remains to-day both exterior and interior, an example of Elizabethan domestic work, the only such in Croydon, and a representative structure perfected and considered in every detail and method.

Such work to an extent endorses the graphic words of the historian, J. R. Green, who in his "History of the English People" wrote (in speaking of the change in architecture in the 16th century) "a social as well as an architectural change covered



PAUL WATERHOUSE, M.A., F.R.I.B.A., ARCHITECT, England with buildings where the thought of defence was abandoned for that of domestic comfort and refinement." Untouched by the Parliamentary forces which devastated, for a time, the old Croydon Palace, Whitgift's Hospital surely claims reverent treatment as an heirloom, not only of the town, but as a monument throughout England. William Morris, whose words still hold sway throughout the land, said of such houses, "Every time one of them disappears is a national misfortune, for while most other mistakes we make may be remedied, the destruction of an ancient building in irremediable."

Not only for architectural value, but for the charitable aim it fulfils, Whitgift's Hospital claims all influential support. By the very words of the Act of Parliament of 1596, "John Whitgift founded a hospital to *have continuance for ever, and to be incorporated.*" Croydon was the Archbishop's home, and his constant retreat, and surely this, his foundation, should for ever stand secure from danger and encroachment. Queen and Archbishop are both associated with this Hospital, for Elizabeth's grant to the founder is still preserved among its corporate papers and archives. Dr. Whitgift, too, was present to soothe the closing hours of the great Queen whose life ebbed away in her riverside palace of Richmond. That fantastic and stately mansion, sometimes called Sheen Palace, had also an architectural history, and the few outlying portions which still remain, tell of the spacious pile, which was the favourite home of the Tudor sovereigns.

[The following paragraph from a recent issue of the "Times" bears the impress of authority, or at all events, of inner knowledge, and seems to set a much-vexed question at rest. As this was a question in which the architectural profession were, for once in a way, able to join heartily with the archæologists, our readers will rejoice at the attitude of the Local Government Board. "It was stated in the 'Times' of August 17 that it was understood that the Local Government Board was in sympathy with the views which had been strongly expressed against the scheme for the demolition of the Whitgift Hospital, Croydon. It may now be taken as certain that the day is very far distant when consent will be obtained for the destruction of the hospital."]

The first, or priming coat, upon a surface of steel in a fit condition to receive paint is of the greatest importance, in view of the circumstances that the union of the paint and the substratum depends entirely upon the adhesion of this coating, and the first problem to be solved in the painting of steel is necessarily—not which paint sticks best on another coat of paint, but which paint adheres most firmly to iron. For a long period red lead alone was employed for this purpose, and even now still enjoys a reputation not altogether undeserved, and, when in competent hands, has given very fair results. It must be borne in mind that of all pigments red lead requires the smallest proportion of oil or varnish in order to form a distributable and well-covering paint; and it must be noted that the protection afforded by the pigment is largely dependent upon the property it has of absorbing and retaining oil. Also, on account of its great specific gravity —(9.19)—the proper mechanical mixtures of red lead with oil is almost impossible, settling and setting take place very rapidly; hence the general practice of mixing in the kettle before the application. The best priming coat is obtained by the use of orange lead, a pigment of lower specific gravity—(6.85)—and of finer texture, which, when mixed in certain proportions with an inert pigment having a great oil-absorption, produces a paint which can be properly ground and mixed for use, having, by reason of its fineness, great adhesive power, and capable, owing to the presence of the inert pigment, of lessening the oxidising action

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

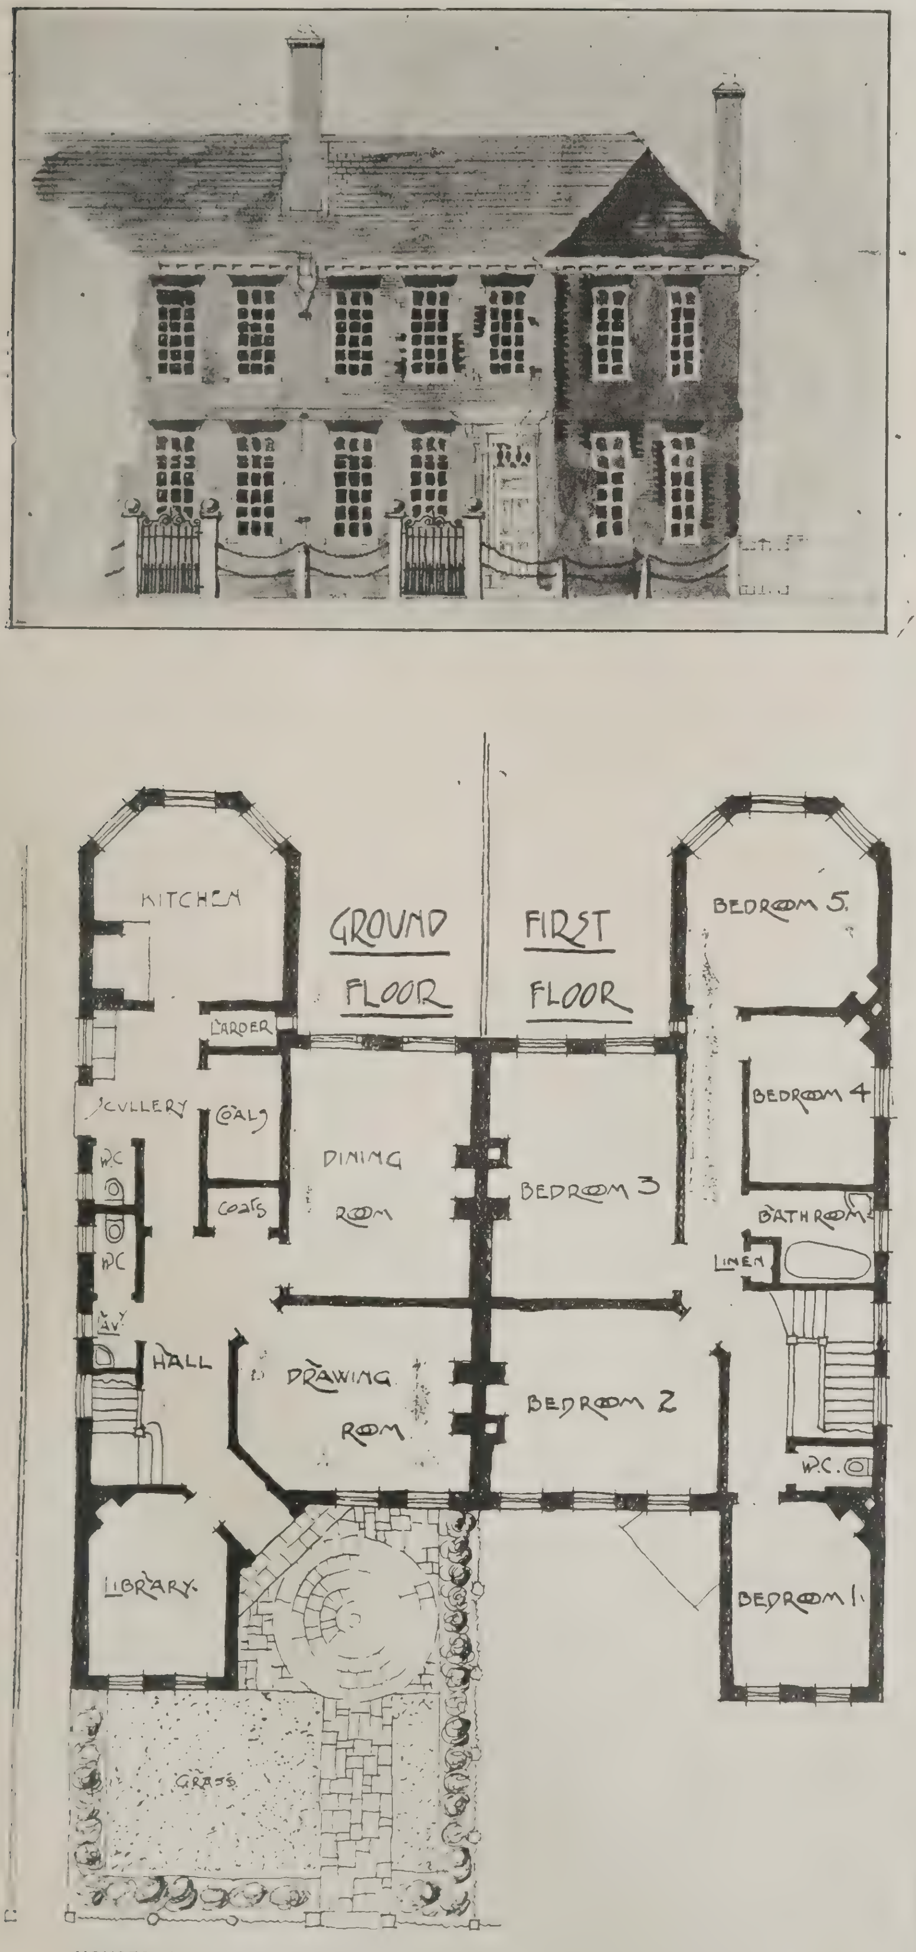
Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.
Oct. 11.	HULL TRAINING COLLEGE for Teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd, and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.
Nov. 30.	HERNE BAY PAVILION ON PIER. Herne Bay Urban District Council invite competitive drawings for a pavilion to be erected on the proposed extension of the pier at a total cost not exceeding £4,000, exclusive of architect's commission. Premiums of twenty-five guineas and ten guineas respectively will be awarded for such two designs as shall be judged of sufficient merit by the Council, and placed by them as first and second; the premium of twenty-five guineas to be afterwards merged into the usual commission payable to the architect, provided the work is carried out by such competitor. Plan of the site and copy of the conditions may be obtained on application to the undersigned on and after the 24th instant on payment of one guinea, which will be returned on receipt of a bona-fide design. Drawings to be deposited at the Clerk's Office, Town Hall, Herne Bay, not later than noon on the 30th November next.—Joseph Jubb, Clerk to the Council, Town Hall, Herne Bay.
No date.	NATIONAL MUSEUM OF WALES The Council desires to receive competitive designs for the erection of a new National Museum at Cardiff, Three premiums are offered. The Council have appointed Sir Aston Webb, R.A., Mr. John J. Burnet A.R.S.A., and Mr. Edwin T. Hall, F.R.I.B.A., as Assessors. Particulars and plans of the site will be supplied to competitors on payment of a fee of £2 2s., which will be returned on receipt of a design in accordance with the conditions, or if all papers are returned within 14 days. Inquiries to be addressed to Dr. Wm. Evans, Hoyle. Director of the Museums. City Hall, Cardiff.

Burslem and Stoke Town Halls.

Several leading articles, and a vast amount of correspondence, have been published in the Staffordshire papers relative to the Burslem and Stoke competitions. The excitement at Burslem seems to be very largely a matter of local feeling. The merits of the chosen design are somewhat grudgingly acknowledged, but complaint is made that local taste, sentiment, and circumstances have been insufficiently regarded, and for this the critics blame neither the assessor nor the successful architects, but the system under which competitions are held. A leader-writer in the "Staffordshire Sentinel" says: "These criticisms do not involve in the slightest degree any reflection upon the skill and the experience of Messrs. Russell and Cooper, who were apparently guided by the printed instructions, which very likely were not sufficiently explicit. Probably no printed instructions could have been sufficiently explicit; local knowledge was desirable, and local knowledge is, of course, not possessed by architectural firms in London, however eminent." This seems to be the gist of the complaint; and it is complicated with an exceeding bitter cry from the distressed ratepayer, who conveys the impression that in these hard times it is wicked to spend money on large building schemes. "Burslem Ratepayer" objects to "hard-earned money being so recklessly and wastefully squandered by such ridiculous schemes as new town halls, etc." Factious elements being so prominent in the controversy, the architectural interest in it sinks almost to zero.—With regard to the Stoke-upon-Trent Town Hall Competition, the exhibition of plans only serves to deepen our regret that, owing to the inability or the unwillingness of the local authority to spend a sufficient amount of money on the project, none of them is likely to be realised in three dimensions. Hence the labours of the assessor, and some exceedingly fine work by some of the competitors, have been rendered comparatively fruitless in consequence of yet another manifestation of the "fault of the Dutch." With regard to the Stoke competition, the assessor (Mr. Stokes) had written as follows:—"A careful examination of the designs sent in for the Town Hall extension competition will, I think, show that the sum of £25,000 is hardly adequate to meet all your requirements. However, of the less costly designs, I am of opinion that the best is Number 33, and the second and third respectively Numbers 1 and 37." The Corporation committee, having considered this letter, and made a detailed inspection of all the designs submitted for competition, could not recommend that any of them was of such a character as to justify the Council in carrying it out, mainly on account of the excessive price. The committee having made a further inspection of the designs placed first, second, and third, were of opinion that as the cost of the first and third materially exceeded the sum of £25,000, they were disqualified under rule 15 of the conditions, and that other sufficient reasons existed for not adopting such designs. With respect to the design placed second by the assessor, although the committee were not prepared to recommend its adoption, they considered that as regarded cost it more nearly conformed to rule 15, and that therefore the premium of £100 (the second prize) should be awarded to its author. The committee recommended that the whole matter should be referred to the Council in Committee. That the committee's position, in condoning in the second design what they have condemned in the first and third, is somewhat illogical need not be insisted upon, logic being the last thing to be expected in public affairs; but it nevertheless seems to place them in an awkward predicament unless the authors of the first and third designs magnanimously waive their claims to the premiums to which they seem to be entitled under the assessor's award. The troubles at Burslem and at Stoke, following so closely on several similar discontents, emphasize the need for careful reconsideration by the R.I.B.A. of the whole subject of competitions. There would appear to be something, or many things, radically wrong with a system that in almost every successive instance produces so much clamour and dissatisfaction.

The restored choir of Selby Abbey is to be re-opened on Tuesday, October 19th next. In response to the appeal issued in June last for £1,000 to complete work upon the fabric, contracts for which had been entered into, the money has been practically secured, but a further considerable amount is needed for furnishing the sanctuary and choir of the Abbey. The Benedictine Abbey at Selby was founded by William the Conqueror in 1069, and raised to the dignity of a mitred abbey by Pope Alexander II. Henry I. was born in the Abbey, and this fact naturally accounts for some of the privileges conferred upon it. The Abbey Church, which has been much changed in appearance since the foundation of the Abbey, was made parochial in 1618.



HOUSES NEAR GOLDER'S GREEN. JOHN W. RHODES, ARCHITECT.

The houses here shown are typical of a series to be erected. While no two sets of plans are exactly alike, all the elevations suggest the same period. The facings are Luton bricks, with red sand-faced long-and-short work, and red rubbed arches. Black sand-faced roof tiles are to be used throughout.

REINFORCED CONCRETE.

By Arthur C. Auden.*

(*Continued from page 132, No. 758.*)

Reinforcement.—Since the issue of the first patent with reference to reinforced concrete in 1831—which it is interesting to note was to an Englishman, and, as far as the author's present information stands, this patent out-dates all others in any country—the number of patent systems, forms, and methods of reinforcement have been very great, of which many survive. However, it is not now proposed to enumerate the various systems, whether patent or otherwise, but only briefly to draw attention to the advantages and disadvantages of such in each particular instance.

First, it may be said that practically every one of the many systems at present in use has good points in which it is superior to others, but it is also certain that no one system has the monopoly of being the best in every instance and in every form of construction. For example, that which is exceedingly good for beams is inapplicable or unnecessarily costly for use in flat surfaces, and the same may be said as regards others for use in columns and not in arches, and so on.

Secondly, it is frequently cheaper to sacrifice a little of the theoretical efficiency of any method for the sake of ease in handling upon the actual work in progress; and all the metal in reinforced concrete being covered up, any error in position due to misplacement or to any part having become loose or driven or shaken out of place when the surrounding concrete is being punned, cannot be seen and put right. It will therefore be readily recognised that any methods involving loose pieces, or such fastened together at many points with small diameter wires, are not so efficient in actual work as those where all the parts are rigidly fixed together.

It is also important that all reinforcement should be so designed as to possess a considerable amount of initial rigidity, so that it does not "sag" or "warp" or "twist" when placed in position in the mould boxes. Many illustrations regarding this could be quoted, but that of compression-bars intended to be above the neutral axis in a beam, sagging down by their own weight till a portion of their length is below the said axis, where it is worse than useless, is not by any means as rare as it should be. The same remarks apply to lateral misplacement, particularly in the case of columns and struts, as well as to the pitching and spacing of reinforcing bars or metal on flat surfaces such as floors, walls, etc. In these last-mentioned it is practically essential to have the bars or metal so designed that they cannot be knocked out of place, as it is almost impossible to keep a number of separate loose bars in proper pitch; it is advisable, therefore, that all reinforcement for this form of work be woven together.

Punching or slitting solid plates into strips or bars is another efficient form of reinforcement for flat surfaces, particularly for those which are approximately square in plan, viz., where the strains are practically equal all over; but for flats where the length is considerably greater than the span, a wire meshing is cheaper, as the cross-span wires take the load, the longitudinal ones being only necessary to keep the others in pitch, and it is not advisable to pay for metal and strength in the longitudinal direction where it is not wanted.

Auxiliary Tension Members in Beams and Slabs.—An examination of all the accepted specifications, for the last ten years, dealing with reinforcement, or a reference to the advertisement pages of technical journals, will show that it is almost universally acknowledged that these important accessories must be inclined to the main tension-bars and *not* be at right angles thereto, and also that such bars must be so designed as to retain absolutely their positions where they are connected to the main tension-bars and cannot be slipped or moved along the same when ramming the concrete or otherwise. The reason for this inclination appears on examination of a slab breaking under a test load. It will be seen that the cracks are not normal to either the neutral or transverse axis, but are at an angle thereto, and it is known that the most efficient way of preventing any two surfaces from coming apart is to spike them together with a nail at right angles to themselves. This reinforcement is therefore designed so as to pass through the weak portion of the beam or slab where cracks are likely to occur, at right angles to such cracks (or planes of rupture) this reinforcement being of course in addition to the main tension-bars taking the main tensional stresses below the neutral axis of the beam. It is not such good practice, though frequently exceedingly convenient, to obtain auxiliary tension members by means of placing a large number of rods or bars in the bottom of the beam and bending up the ends of them at various points, although by this means the desirable inclination abovementioned is gained, but this design involves a considerable excess of metal at the centre of the beam and a greater weight of steel than is required must be purchased.

---

* Part of a Paper read at the Liverpool meeting of the Institution of Mechanical Engineers.

Reinforcement of Struts and Columns.—There are two very distinct methods of reinforcement in use for these—one being that in which the vertical bars are prevented from spreading by being spirally wound with rods or wire, and the other where the same end is obtained by means of rings or loops of wire tying the vertical bars together, such loops or rings being arranged at various distances apart to suit the design and strength desired. Both these methods have good and bad points, each one being the best under appropriate conditions.

The spiral winding has given most excellent results, and is considered by many to be the best for columns, etc., as it permits the use of lighter and fewer vertical rods, but it has the disadvantage of being somewhat difficult to make it a "good mechanical job," that is, so that the spirals shall all be the same diameter and parallel in bore, otherwise some will clasp the group of vertical bars too closely and others hardly touch them, which results in unequal stresses. This is, however, generally made much easier by using bands of flat rectangular section which bend readily, and by first winding the spirals on a cylinder and then slipping them over the vertical bars when made. Great care must be taken when using spiral reinforcement in vertical columns that it is not made in too long lengths, as all the concrete has to be put in from the top of each length, and it is well known that when concrete is dropped from even a small height the mixture of its constituents becomes very uncertain. Care must also be taken that each length of spiral is "corkscrewed" well into the one below it, as otherwise there is a plane of weakness between each length of spiral. This form of reinforcement must be so designed that the required strength is obtained without the pitch of the spiral being closer together than the size of the largest pieces of aggregate used, as if it is so, the stones become jammed between the coils and a lack of homogeneity is the result.

The second method of column and strut reinforcement above-mentioned, namely, loops or rings slipped over the vertical bars and held at the proper distance apart, is also an excellent one, especially when the loops are carefully made mechanically on hard metal formers, so that each one is an exact replica of its neighbour; the result being that each one equally clasps the group of vertical bars, otherwise should one be tight and the other slack the bursting strains will not be taken up by all the loops in equal proportions. As the first desideratum of this design of column and strut reinforcement is the prevention of the vertical rods spreading apart under the load (the loops themselves being further apart, do not resist the bursting strains on the concrete to the same extent as the spiral windings), it is not good practice to allow the loops to be curved in between the points where they touch the vertical bars. Unless the wire or rodding forming the loop is straight between its resistance points, it does not get a chance to develop its tensional strength, as it must "pull itself straight" first, which it does at a low stress. For this reason the use of comparatively high-carbon steel is often recommended for columns or strut loops, as it is stiffer to resist distortion; and as distortion is one of the main things to avoid, particularly in this phase of reinforcement, the use of harder steel, if the same can be obtained without any marked increase in cost, appears to be certainly indicated; in fact, as the elastic limit of all reinforcement is almost of as great importance as its ultimate strength, the use of bars and rods possessing considerable resistance to stretching is certainly to be recommended, provided that the said ultimate strength is not appreciably decreased. The use of high-carbon steels has been recommended for various other reasons.*

It is often said that it is immaterial whether the reinforcing rods are bent or not, as, being bedded in concrete, they are immovable, and doubtless this may be true in a structure where there is no vibration and where the loads are unvarying in amount and disposition; but where it is not so, there is a tendency on the part of the concrete on the concave side of the curved pieces of wire or rodding to become friable, and this tendency should be eliminated in the design by working the reinforcement in straight lines whenever possible. It should also be noted that all the joints of the vertical rods in columns and struts must be in close-fitting sleeves—preferably of good quality lap-welded steam barrel.

When designing reinforcement there are of course many points for consideration quite irrespective of the particular method of constructing or attaching the various parts or members, one of the principal being that all beams or floors running continuously over the tops of columns or stanchions or walls must be reinforced above their neutral axis where they pass over the said columns, in exactly the same way as they are reinforced below that axis in their clear span, as the parts in tension and compression are reversed in these circumstances. In one well-known system the bars are run along both top and bottom surfaces from end to end, but these rods or bars in the compression area are only provided as a means of keeping the shear-members or loops or stirrups in position, not as reinforcement against reverse flexure, nor as such in compression, this last not being needed unless the area above the neutral axis is such that it cannot stand the allowable crushing stress.

The exact position of this neutral transverse—or, more correctly speaking, diagonal—plane of "reverse flexure" has not so far been very exactly located, and it will of course vary with every variation in the distribution of the load. The present practice is therefore to design the reinforcement, over the supports, to overlap the ends of that which runs along the "belly" of the beam. The diagonal auxiliary shear-members connected to each of the main tension-bars above and below the neutral axis thus become parallel to each other, in the same way as the tension members in a lattice girder. The same arrangement must be carried out where the ends of beams rest on and in walls. As will be noted, the ends of the bars are bent downwards into the beam itself when only the beam is in reinforced concrete, but, should the whole structure be of this material, the beams and walls consequently being all monolithic, it is better practice to bend the bars upwards, this being also handier as the men can readily see, and, if necessary, adjust, any bar which may have been displaced by punning or otherwise.

When designing long and deep beams or girders, such as for a railway bridge with flat (not arched) spans, it will also, not infrequently, be found that the available area of concrete in compression above the neutral axis is such that the stress per square inch is more than the concrete will safely stand, that is, more than 550 to 750lbs. per square inch according to the class of concrete and the nature of the aggregate used; but this is easily overcome by using reinforcement in the compression area, always remembering that the value of steel in compression is 50 per cent. less than that of the same in tension. Here also the question of rigidity to resist deformation under compression is important, exactly as it is in columns and struts, and care must be taken that all the separate members in compression are properly braced together to avoid the tendency to spread in any direction, but particularly sideways and downwards. Even with ordinary beams supporting floors this question of the available area of concrete in compression demands consideration, but, the floor and beam being all in one solid piece, not only does the part of the floor immediately over the beam contribute to the desired area, but portions of the floor on each side of this are available also, thus enabling us to regard the beams as of T section, but, except under special conditions of loading, the breadth of floor which we can consider for the purpose of this calculation should not exceed four to six times the breadth of the beam itself, according to the class of concrete and the nature of the aggregate used. But, even with this reservation, this fact of the beams and floors being solid together enables a wonderfully strong and light structure to be obtained. The same diagram also shows in closer section an additional means of obtaining this larger area of concrete in compression, namely, that of making fillets at the junction of the beam with the floor.

Another point to be remembered is that temperature stresses must be carefully guarded against, and that extra reinforcement—in fact, increased scantlings over all—must frequently be adopted for this purpose; as the coefficient of expansion of steel and of concrete is practically the same. In structures such as bridges these variations due to the temperature can be arranged for by the ordinary hinges or expansion joints (of which the latter can be very rapidly and effectively made with thick sheet-lead, the area being such that no pressure it will experience will cause it to "squeeze out"), but in the case of structures where such are impossible, as for instance in an exposed tank or bunker or silo, the only remedy appears to be a general increase in strength, particularly by means of increased reinforcement, and, although perhaps contrary to theory, this method has proved perfectly successful.

Centering.—With reference to the design and erection of forms or centering for keeping the soft, wet concrete in place till it is properly set, there are two main conditions which must always be fulfilled. First, it must be so supported and stayed that neither the weight of the concrete, nor the ramming of it, can make the centering bulge or sag; and secondly, it must be as close-jointed as possible, otherwise the water will leak out and carry with it an appreciable amount of cement, which will weaken the structure. There are many methods of obtaining a smooth face on the finished concrete, such as painting the boards with oil or whitewash, or any material to prevent the concrete adhering to them, but, given fair flush joints in the woodwork, the passing of a thin piece of sheet steel (an old hand-saw with the teeth ground off is excellent for this purpose between the concrete and the board gives, perhaps, the best result whenever the general arrangement permits of its use. When work is to be floated or rendered, a rough surface is of course desirable.

---

* Mr. Charles F. Marsh, in a Paper read before the Concrete Institute, stated: "For hooped members, if the allowable compressive stress in the concrete is higher than about 1,000lb. per square inch, it is advisable to use high-carbon steel for the longitudinal reinforcements, and the employment of high-carbon steel for the bindings is always advisable. For the purpose of resisting temperature stresses there is an advantage in the use of high-carbon steel, as its greater resistance will enable it to offer more assistance to the concrete."—Transactions, Concrete Institute, vol. i, page 7.

The question of centering leads naturally to that of the length of time it should remain in place. The author is frequently asked to state his opinion on this *in general*, but no general or hard-and-fast rule is possible—on some jobs or portions of them, 24 hours is ample, on others six weeks is too short. Much depends on the weather, particularly on frost, and much on the over-all scantlings of the various pieces, but, most of all and beyond everything, on experience; in fact, there is no material where experience on the part of the constructors is more important than in all matters connected with reinforced concrete or where more disastrous consequences are likely to follow the lack of such experience. In this connection it is interesting to note the following extract from some remarks made by a gentleman who has done more than any other to place reinforced concrete on a firm basis, namely, Mr. William Dunn, F.R.I.B.A., who said in a paper which he recently read before the Concrete Institute, and from which he has kindly given the author permission to quote:—

"Suppose, however, that the design has been carefully checked, initial difficulties got over, and the work begun, the superintendence of the work is merely the transference of our anxieties to another field. I am very strongly of the opinion that no work of importance should be entrusted to men without experience; our best safeguard against defective work is undoubtedly the skill, experience and honesty of the contractor.

"No engineer or architect, unless he spends all his time during the execution of the work in actual and constant supervision, can secure his employer against dangerous errors on the part of the workman. In steel construction we can examine and measure every part after it is up; not so in reinforced concrete work. Once the concrete is laid we cannot tell, except by cutting into it, whether there are six 1-inch rods or two ½-inch rods inside a beam or pillar, or whether these are 2 inches or 4 inches from the surface. To see that the drawings are actually carried out requires a conscientious scrutiny and attention every minute of the time the work is being done. Much may be observed during a visit, but not everything.

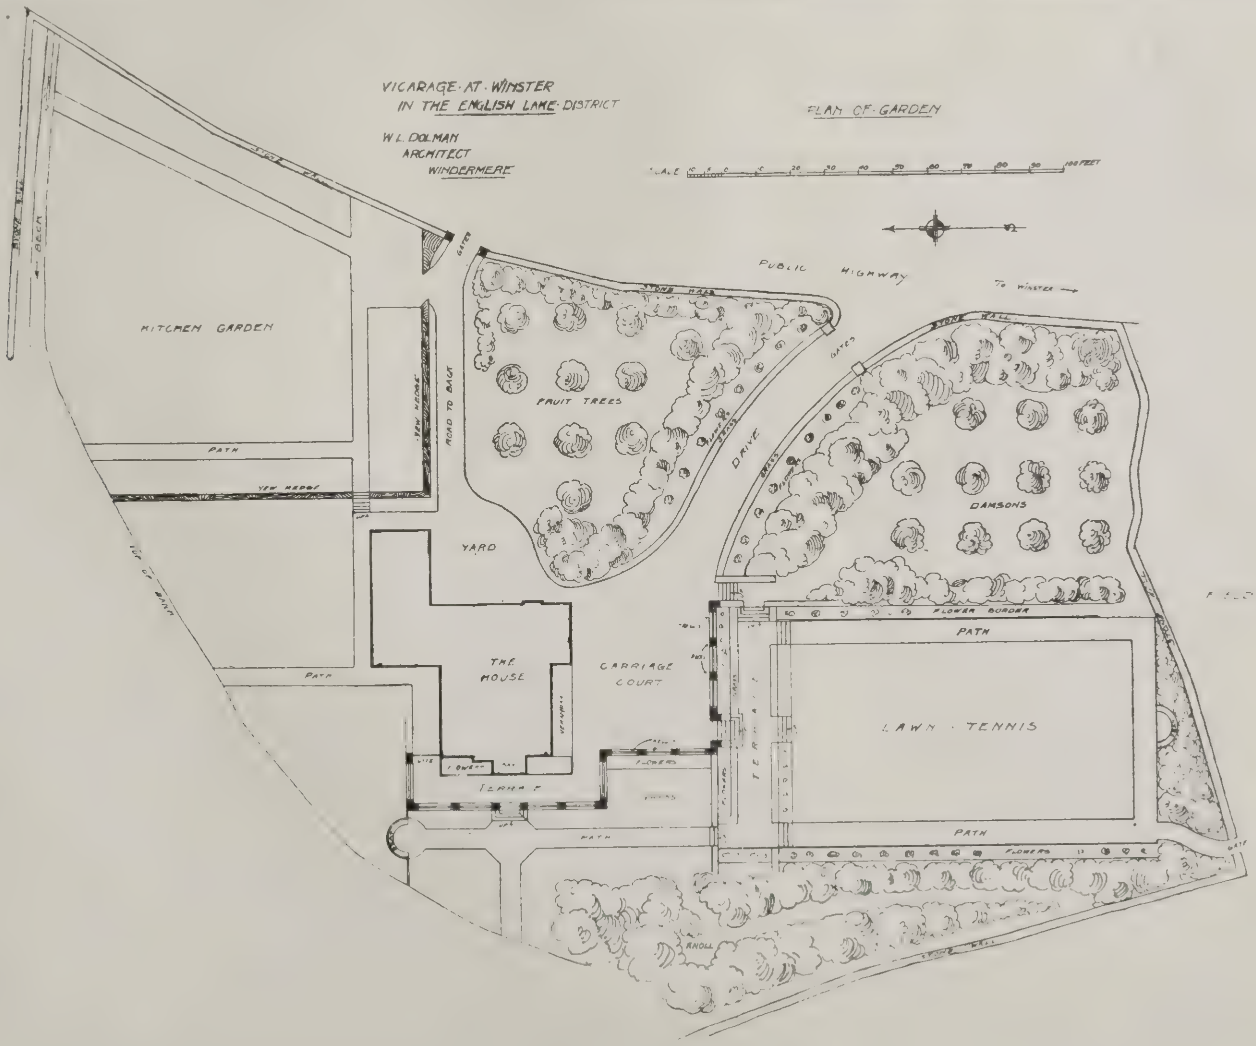
"The number of skilled contractors, clerks of works, and others, constantly increases, and we shall soon all have had experience in this material. But with all the care possible there is a serious risk in employing an inexperienced contractor."

A contractor with considerable resources in the way of plant and materials is also very advisable. It is not long ago since a somewhat serious collapse occurred in a job where the concrete was put in on a Friday and the centering struck on the Monday, as the contractor had not, and could not get, any more timber!

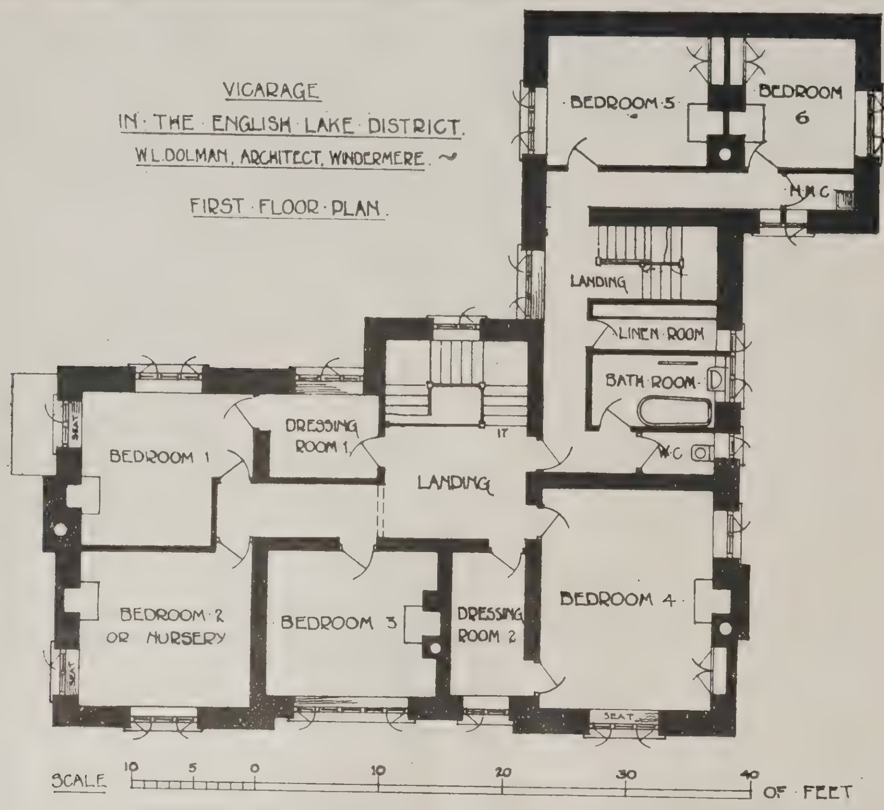
Calculations. — Dealing with ordinary work, such as beams, walls, and floors (which last can be regarded as beams for the purposes of calculation), the simple formula which has been in use by engineers during the past fifty years when calculating the strength of rectangular beams, is eminently suitable for use in designing reinforced concrete. The author has made many calculations and tests to ascertain reliable values for the constant in that formula, which he hopes to be able to communicate at a later date, as also such for use with column and strut formulæ.

Standardization.—The adoption of a series of constants in any set of calculations is useless unless the primary conditions governing the calculations are equal. For instance, the value of the constant, just referred to, is immaterial if the proportions of the concrete or the amount of reinforcement is altered, but these matters are becoming rapidly standardised, and if the proportions of one part of cement to two parts of sand and four parts of stone (this last all to pass 3-in. mesh and refuse ⅛-in.) be adopted, the result need not be feared. This proportion may be also expressed for ordinary use—three 2-cwt. bags of cement, ½ cubic yard of sand, and 1 cubic yard of stone, the mixture resulting in one cubic yard of concrete in place, as the sand and cement are only very little more than sufficient to fill the voids between the stones. This question of voids is important, because certain classes of stone lie much more closely together than others, and it is therefore possible to economise in the purchase of sand, but this is entirely a matter for experience, as a glance at the mixing of the first batch will give more information than the most elaborate calculations.

As regards the percentage which the cross-sectional area of the reinforcement in tension is of the cross-sectional area of the beam or wall or floor, this varies between ¾ of 1 to 2 per cent., but if 1½ per cent. is allowed for in ordinary work, it is quite safe, and may be used as a standard for calculating quantities. Very frequently, however, both this matter and that of the proportions and ingredients above-mentioned have little more than an academic interest for the general user. To take a very common illustration—a works-manager decides to erect a travelling-crane in one of his shops, and proceeds to order the rolled-steel joists to carry the wall-rails—he knows his loads and his spans and that he can buy joists at so much per ton of such-and-such a section at such-and-such a weight per foot, which are guaranteed by some reputable steel-maker to carry the load



(See Centre Plate.)



required at the span decided upon (it must be remembered that we are not now considering any instance needing web or lattice girders, but strictly ordinary work only). He orders his joists without troubling about what proportion of carbon or silicon or anything else is contained therein, and the same procedure can frequently be adopted with regard to reinforced concrete, using the formula before-mentioned or some other similar, to find the scantlings so as to get out the amounts of materials required in order to ascertain the cost. He, the works-manager, may be quite certain that no reinforced-concrete maker of repute will risk his name by putting in bad materials (or good materials wrongly disposed) any more than will the steel-maker with reference to the rolled-steel joists.

Methods of Using.—Reinforced concrete is now so largely and widely adopted that a list of even a portion of the various uses in which it has been already employed would extend to a great length. The following are a few remarks with reference to some of its better-known uses.

Buildings in General.—All buildings should be of skeleton framework construction. The spaces or panels between the columns and beams can be ⅛-inch filled in with reinforced concrete or with brickwork, or the whole frame covered with a skin of stone or brick; but as the main strength is in the frame, such panels can be quite thin, in fact only of such thickness as is needed for dryness, not for strength, which results in a large increase in floor area, particularly in the lower storeys, where, otherwise, the walls would have to be of considerable thickness.

Boats and Barges.—These have been successfully built for several years, and, provided several are ordered of one size, that is, made off the same moulds, they are very much cheaper than steel.

Chimneys.—From current quotations these certainly appear to be cheaper than the same in brickwork, and of course do not need pointing; but there may be a difficulty when one needs to be felled, as at present it is not known how to bring one down in a small area. It is, however, a simple matter if there is space available for the chimney to fall in one length.

Drain and Sewer Pipes.—Many miles of these have now been laid and are giving great satisfaction both as regards first cost and upkeep. Great care is, however, necessary in their manufacture to ensure the reinforcement, both longitudinal and circular, being exactly in its correct position, otherwise there is a great risk of the sewage or water reaching some of the metal and the life of the pipes being therefore very short. One of the great advantages of reinforced concrete sewer-pipes—particularly in bad ground, for instance over old mine workings is that they do not cost any more per yard when made in long lengths, up to, say, 18ft. if required; thus about 75 per cent. in the number of joints is saved and they are able to carry the weight of themselves and contents over spans practically equal to their own lengths. The same remarks also apply to water-pipes.

Dock, Retaining and Reservoir Walls.—The author has already noted the saving in space in buildings due to the use of reinforced concrete, and such is even more the case with these walls.

Fence Posts.—The use of these is increasing very rapidly, but up to the present they are rather handicapped by the want of a cheaper method of attaching the wires to them, the ordinary hooks or staples being practically inadmissible, as they get bent and broken when the posts are bundled for carriage, and clips and bands or screw-plates are costly.

Magazines for Explosions, Safes and Strong Rooms.—Owing to its practically absolute fireproofness, reinforced concrete is particularly suitable for these structures, and recent large and costly experiments in Germany have proved that even the explosion of huts containing 1½ to 2 tons of gelatine dynamite did no damage to their surroundings other than from the air-blast. It was found that the reinforcement was only rent but not scattered, and the concrete blown away in the form of coarse dust.

As regards safes and strong rooms, it can only be said that, although a considerable number have been built, they are still awaiting an actual test at the hands of those skilled in the art of "safe-breaking."

Piles, Piers and Jetties.—One of the principal points to bear in mind when considering the use of reinforced concrete piles is that they will safely carry about three times the load of such in wood of the same cross-sectional area, also that they are no more difficult to drive; and, with reference to piers and jetties, the use of a material which does not deteriorate "twixt wind and water" is a matter worthy of very careful consideration.

Pithead Gears and Pit Props.—These being fireproof is their strongest recommendation, and the latter, if made hollow, are, strength for strength, but very little heavier than ordinary wooden props.

Railway Sleepers.—As the most important question in relation to these is their life, not their strength, nothing but time will prove whether the use of reinforced concrete at a somewhat higher cost than wood will be the more economical in the end, but about five and a half to six years' experience of sleepers in continuous service under heavy traffic and rolling stock so far show no appreciable difference from the day they were laid down, and a recent order for over 100,000 of such shows that they are being extensively adopted.

Telegraph and Tramway Poles.—These are rapidly coming into favour, and very large numbers have been already erected. The fact of their not suffering from corrosion or rust, and therefore not needing painting, together with their being, at present quotations, considerably cheaper than steel, probably accounts for this demand. As they are tubular very great care is necessary in their manufacture so as to ensure that the reinforcement is absolutely accurate in position.

Painting.—The question of painting, although only now referred to, is one of vital importance with all reinforced concrete structures (other than buildings such as houses, offices, etc., which are usually plastered and papered), as it is well known that all naked steel and iron work deteriorates rapidly from rust and corrosion unless it is periodically very carefully scraped and painted. Even when this is done, the amount which is, rightly, deducted for depreciation in the case of a valuation for sale, transfer, mortgage or similar, is very marked, in addition to the actual cost of such scraping and painting. This is particularly the case with bridges owing to their exposed position, and the expense of painting them is frequently considerably increased by the extra cost of the necessary cradling and scaffolding. All this is eliminated in the case of reinforced concrete, which increases in strength with age and is not subject to depreciation, nor are painting or scraping or other methods of preservation necessary. In fact, when comparing the cost of a reinforced-concrete structure with that of a similar one in other materials, it is quite a good rule to work out the cost of the painting and upkeep, and, having capitalized the same at a rate per annum (say one per cent. over the current Bank Rate), to deduct this sum from the estimated cost of the reinforced concrete in order to place both propositions on an equal basis for purposes of comparison.

The author is fully aware that one of the very important questions relating to reinforced concrete from the users' point of view is that of the attitude regarding it of the various authorities, both those governing the country as a whole and those governing each municipal or county area. In some cases it is certainly true that serious restrictions have been placed on the use of this material, but these adverse views are rapidly decreasing, and it is only a question of time till they are eliminated altogether in exactly the same way as the strenuous opposition to the use of iron and steel in buildings or in ships has now disappeared. With reference to municipal restrictions, in Liverpool they are more fortunate than in any other city in the kingdom within the author's knowledge, as each reinforced concrete proposal is considered solely on its merits. Not only must the plans be deposited as usual, but also all the calculations, which are carefully checked. If they prove satisfactory, permission is given to proceed with the structure as designed without any of the vexatious regulations, such as those regarding the thickness of walls which are frequently enforced in other towns quite irrespective of what the said walls have to carry or the strength of the material.

THE FIRE IN CANNON STREET, LONDON.

The accompanying illustrations, which have been reproduced from photographs taken at the scene of the fire that occurred on August 22nd at a large block of business premises between Cannon Street and King William Street, E.C., show, respectively, the effects of the fire in the confined space of a kind of light-well, and the appearance of (1) glazed bricks, and (2) glazed tiles after subjection to this ordeal. It will be noticed that the defacement of the glazed bricks is very thorough, and that some of the tiles have dropped out. The fire appears to have started in a basement, and, when it was first observed, had spread through the lower part of buildings extending 150ft. in one direction and 70ft. in another, and Mr. S. G. Gamble, who was temporarily in charge of the Fire Brigade, set on a force of seventeen steamers, three horsed escapes, four long ladders, motor hose tenders, and 120 firemen. Three large buildings, occupied by about thirty different firms, were "well alight" when the brigade got to work, and the firemen were mainly concerned in preventing extension to surrounding buildings. In this object they were extremely successful, and but for their activity and skill the fire might have assumed enormous proportions. As it was, the damage was mainly confined to two buildings in Abchurch Lane, and one in Cannon Street, which were burnt out. These buildings were five or six storeys high.

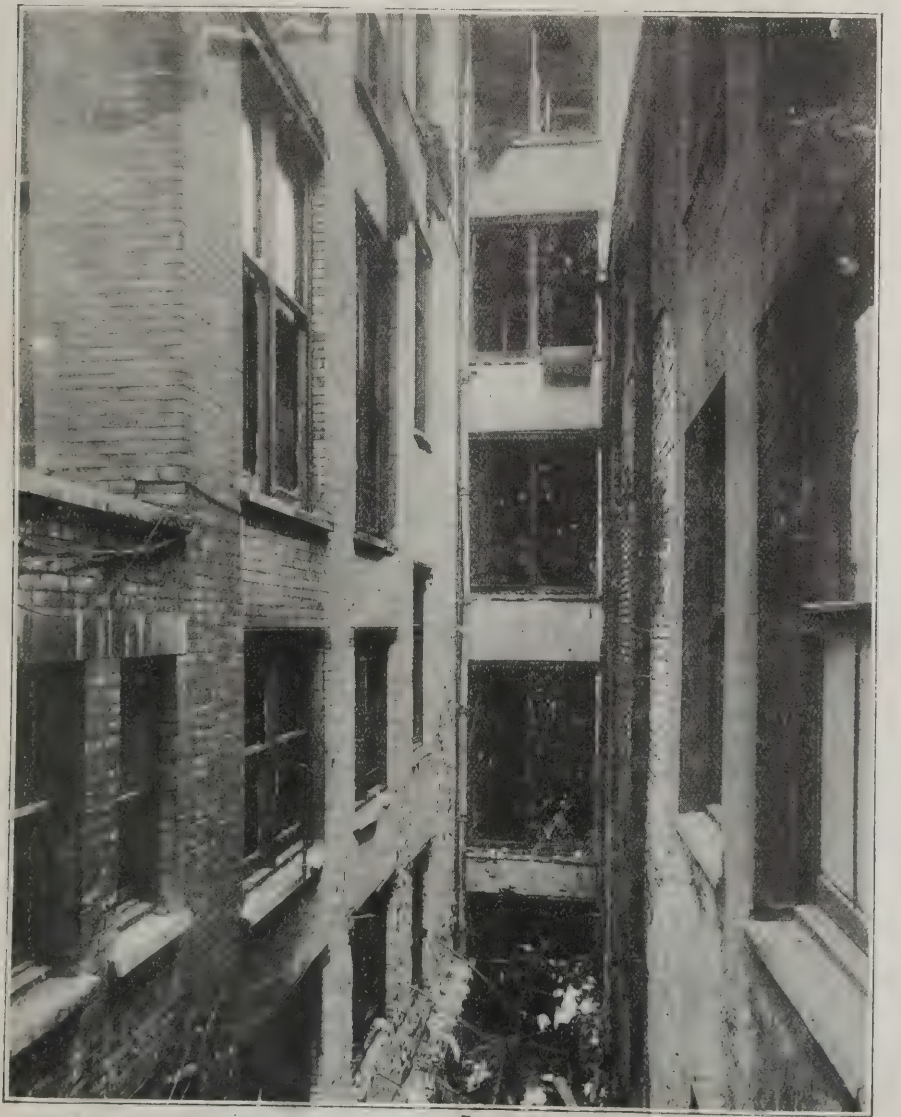


Photo: Bolak.

THE EFFECT OF FIRE IN NARROW LIGHT-WELLS AS EXEMPLIFIED IN THE CASE OF THE CANNON STREET FIRE.

This fire, which occurred in a basement café, burnt through the skylight, and affected no fewer than fifty-five offices lit from the court above.

FIREPROOFING COUNTRY HOUSES.

Mr. Frederick Squires, who, with his partner, Mr. Wynkoop, is doing a great deal of work in the erection of fireproof country houses in the United States, has published an interesting description of the methods that his firm is pursuing. He admits that tile, in common with concrete and other materials, is probably still far from its ultimate development, and that many of its qualities are not yet fully understood. Dampness is perhaps its worst enemy, and in order to avoid it the greatest care is required in the method of constructing doors and windows in tile walls. The sill is especially vulnerable, owing to the lack of firring.

In general, a fireproof house, be its walls of brick or tile, has a concrete foundation up to the underside of the first floor beams. Spans are best kept down to about sixteen feet, interior bearing walls carrying the beam ends. With a little adjustment in plan these bearing walls may be made to carry up through the building. Where openings are wanted, concrete girders may take the place of the walls, and, if too much weight is thereby concentrated, their ends may be carried on concrete piers instead of tile walls, although this is seldom required. Pipe locations should be very carefully studied, as carelessness in this way may result in cutting which will seriously reduce the strength of the structure. The following is a part of tile specification for a country house, and is quite typical.

Concrete floor beams.—All floor beams to be 4in. by 8in., of concrete, 1, 2, 4 and reinforced with one $\frac{5}{8}$in. twisted iron rod secured in place one inch from bottom by nailing to blocks in form. These rods to be bent up at 45 degrees at a point six inches from their bearing, and to run to within one inch of the top of beam and to continue parallel with the top of the beam to the outside of its bearing. All beams to follow framing plans provided by architects, which plans will show sizes of girders, lintels and all structural concrete members.

On top of floors lay sleepers at right angles to beams and bed in cinder concrete.

All lintels that carry ends of floor beams to be 12in. deep by the thickness of the wall and to be 12in. longer than the width of the opening and reinforced as specified for floor beams.

Sills.—All sills to be of concrete cast on the ground and to have a drip and to be detailed on top to fit a rebated wooden sill.

Terra-cotta Tile.—No bearing wall, outside wall or floor to be built of tile less than 8in. thick. Non-bearing partitions to be built of 3in. tile. Window and outside door frames to be detailed with a strip on the outside which will bed in the lintel at the top and will fit between 4in. and 3in. tile, which will form the jambs. Frames to be provided with a bevelled strip on outside casing, which will be removed after stucco has been applied, the space caulked with oakum and the joint covered with a mould. The sills to be rebated on the bottom to cover the rebate in the cast concrete sill and for a weather-proof joint.

All interior and exterior frames to be built with the masonry as it goes up. Interior openings to be formed with wood bucks the width of the tile wall in which they occur.

Of course, there are many forms of steel reinforcement which could very well be substituted for the twisted bar specified above. The designer has a wide range from which to make his selection, and each form has its advocates.

Solid brick exterior walls may take the place of terra-cotta tile, and this is still required by some departments, as Manhattan and Brooklyn.

It was through the Church of St. Luke the Evangelist that the firm got its idea of building fireproof buildings. This building is of brick with a hollow wall and a brick interior and tile and concrete floors. This construction gave such an impression of solidity and permanence that it was shortly followed by the Interlaken house, but by that time the architects had learned that by using tile they could lay their hollow wall twelve inches at a time and all in one piece.

The building departments of most of the towns where these architects have built have accepted fireproof construction after investigation, and in many cases have welcomed it in the hope that it would displace frame. Contractors, whenever they have been thorough workmen, have found no great difficulty in mastering the idea, and some of the firm's best executed buildings have been the first attempt in this line of clever local masons.

Mr. Squires concludes his interesting article (which appears in "The American Architect" for August 11th) with the observation that if good contractors will give fireproof materials earnest thought, well-trained architects will give them careful study, and owners will pay a higher price for a superior article, they will, between them, produce buildings of such a character that everybody will be glad that they can't be burned down.

According to a German trade paper, reinforced concrete construction has hitherto made but little progress in Germany as compared with the great strides that have been taken in other countries, the municipal authorities of the Fatherland having opposed it under all sorts of more or less frivolous pretexts. This opposition, however, now shows welcome signs of yielding steadily, as it is in Great Britain, before the clear demonstrations of the manifest advantages of this form of construction for certain classes of buildings.

Fire Prevention Notes.

Private Fire Brigades. The servants at Windsor Castle, who number nearly a hundred, are being instructed in the duties of firemen. Chief Officer Starie, of the Royal Fire Brigade, is drilling them in sections, and they are rapidly becoming proficient. As this announcement has been made in the daily Press, it is presumptively news. Yet one would have supposed, as a matter of course, that a well-drilled domestic fire brigade had long been regarded as an indispensable part of the equipment of all the royal palaces, as well as of all public buildings, institutions, clubs, schools—in fact, in all large buildings where a few or many men are available for systematic instruction in the methods for suppressing outbreaks of fire, and of using fire-escape apparatus. We can hardly believe, therefore, that the amateur fire brigade at so important a building as Windsor Castle is an innovation. The newspaper item referred to was probably suggested by improved organisation of an existing brigade. In any case, the news is very welcome; the example of Royalty being so much more potent than all the precepts of experts. Private fire brigades are doing, in a quiet way, an enormous amount of good work in the prompt suppression of incipient outbreaks.

Fire Insurance Surveying for "Stickit" Architects. In the current issue of a certain popular weekly periodical there is an article headed, "An interesting Profession: Fire Insurance Surveying." The duties of the surveyor are tersely summarised. He inspects buildings covered by the company he represents, draws up plans and reports of the premises, details processes of manufacture, points out defects in provision against fire risks and suggests remedies, and examines and tests appliances for the extinction of fire. The occupation is said to possess considerable variety and interest, sometimes taking the surveyor far afield—even on to the Continent and into the Colonies. The work is fairly well paid. A surveyor with mature experience receives a salary of anything from £200 to £500, though before he attains to the requisite degree of ripeness his salary may be "anything" (or perhaps nothing) up to the giddy height of £20 a year, "increasing at the rate of £10 per annum." The aspirant to this career should enter some insurance office as a junior, keep his eyes very wide open, study the journals of the Insurance Institute, practise plan-drawing, and acquire some knowledge of building construction. Whether or not it is absolutely necessary to "go in on the ground floor" does not appear. If competence, actual or potential, is a sufficient passport, here is a career to which the unemployed or underpaid architect's assistant might well turn in the forlorn hope that it would give him brighter prospects than the lamentably overcrowded profession in which he may happen to find himself somewhat badly bunkered. The article to which reference has been made appears in "T.P.'s Weekly" for August 27th. In venturing to develop from it the hint just given, we feel bound to add the reminder that, in this congested country, it is altogether beyond probability that the one profession for which there is a dearth of candidates is that of fire-insurance surveyor!

Three Big Fires. The great fire at Glasgow spread with such amazing rapidity, and was so completely destructive—leaving, in the buildings chiefly involved, hardly one stone standing on another—as to suggest the supreme importance of arming authorities with power to insist on the adoption—at least in the great buildings of great cities—of every known and practicable means of preventing such catastrophes. It should be insisted that every compartment of such buildings should be rendered as far as possible insular or self-contained, so that any outbreak could be confined to the point of origin, and that the combustible materials in it should be rigidly restricted to the movable contents—such as the stores of stationery, wines and spirits, and provisions, with which some of the Glasgow buildings are stated to have been replete—and should certainly not include the materials of construction, which should sturdily resist fire instead of joining with a light heart in the general conflagration. The necessarily extensive rebuilding should of course embody the latest fire-resisting principles, but the public, whose property and lives depend to some extent upon the issue, are too ill-informed and too apathetic in such matters to know or care whether or not their interests are being efficiently safeguarded. The more recent fire in Cannon Street, London, might easily have covered a much larger area but for the splendid energy and skill of Mr. Gamble and his merry men. Perhaps the inquest on this fire may bring out more points than are at present available for consideration. A properly prepared digest of these enquiries should supply valuable data for the students of fire prevention; but the newspaper reports of them are so exceedingly meagre and scanty as to be almost entirely valueless from this point of view.

Tile and Concrete Fireproofing. There is being waged in the States, it appears, an internecine war between rival material interests. Upon one point only are the rivals agreed, and that is that the man of property has got to have his house fireproofed, whether he wants it or not. The strife begins in arranging the details of this very desirable consummation. Of the one party it is said that it must be done with bricks and tiles; of the other, that concrete is your only ware. The noted architectural firm of Squires and Wynkoop are incurring the love or the hatred of both parties by using both classes of material in conjunction. Mr. Frederick Squires boldly lays claim to a fundamental art value for the resultant building—that of simplicity. The materials, he says, are more structural than those in which the architect has been accustomed to work, and the result is a more direct and simple building than his previous efforts. "The natural avoidance of wood decoration in a fireproof house," he continues, "has worked wonders in simplifying exterior and interior. The fact that the building is apt to stand for a long time makes for a simpler and thus for a better country-house architecture." The illustrations that he gives in "The American Architect" of houses that he has built of this material certainly look comely and simple; but he solemnly warns his architectural brethren who are as yet without experience in this system of construction, that the appearance of extreme simplicity is apt to be very misleading in any inferences as to cost; and has led many a contractor astray in his figures. That the building is much more costly than it looks is unfortunate, surely, with respect to the equanimity of the client. He always thinks that a building is more costly than it looks; and

THE EFFECT OF FIRE ON GLAZED TILE WORK, AS EXEMPLIFIED IN THE CANNON STREET FIRE.

This view shows the effect on tiles lining one of the staircases.

any system that tends to heighten this inconvenient illusion is severely handicapped in the struggle for popularity. Still any system that ensures a dwelling that is at once comely and fireproof, and of which actual examples are in existence, is worthy of close attention, and we have therefore much pleasure in giving, on another page, some particulars of Messrs. Squires and Wynkoop's tile-concrete fireproof houses.

Printing Office Fire Risks. The paper by Mr. Ralph Hazell, on fire risks in printing offices, which we reproduce in another part of the present issue, is as it were illuminated by a great fire that occurred on Sunday last at Messrs. McCorquodale and Co.'s extensive printing works in Cardington Street, Euston, N.W. The damage, which is said to be estimated at between £40,000 and £50,000, is stated to be fully covered by insurance, and the possession by the firm of other extensive works will no doubt prevent any serious interruption to business. Block "A" of the premises was burnt out; but it is important to notice the statement that the main block was saved by the interposition of fireproof doors.

A telegram from Krementchug, in the Government of Poltava, states that a serious fire has occurred there, and that two sawmills and ten large stacks of timber have been destroyed. A large number of dwelling-houses have also been burnt down, and about a thousand families are homeless.

* * *

An earthquake-resisting system of construction which has been patented by Professor Eugène Boermel, has steel foundations which absorb the shock buffer-fashion.

* * *

The work of preserving the Moot Hall, Dewsbury, a building that dates back to between 1250 and 1300, is at present in hand. The architect's estimate for the work is £750, but the committee, at present, are only committed to an expenditure of £600. This includes the making good of the Moot Hall and the pulling down of certain buildings adjoining, which, when removed, will leave room for a back entrance to the Church House. The Hall is to be provided with a new entrance and porch, and its ancient walls and stone-work are to be made good. A new floor will have to be laid, and the chimney, now about fourteen feet wide, has to be re-built. All the old windows are to be preserved. The principal item of expenditure which the committee have left over for the present is an oak ceiling, to cost about £100. The work is being carried out under the superintendence of Mr. A. H. Kirk, architect, in consultation with Mr. J. Bilson, of Hull, a prominent member of the Yorkshire Archæological Society.

FIRE RISKS IN PRINTING WORKS.

Dealing with the causes of fire in printing works, which are notoriously heavy fire risks, Mr. Ralph C. Hazell, in a paper read at a conference of the Federation of Master Printers, cited the following most frequently recorded causes of fires in printing works:—Faulty construction of flues, etc., hot ashes and sparks from fires, drying of materials, swinging gas brackets, and gas supplies generally, heat from gas engine exhaust pipes, and from slow-combustion stove pipes, spirit vapour coming into contact with naked lights, matches thrown upon the floor, defects in electric wiring and machinery, spontaneous combustion of oily rags, and fire transmitted from adjoining premises.

Mr. Hazell then gives as the reason why fires occur more frequently in printing works than in some classes of factories, the fact that the printing trade is subject to spells of rush work and of irregular night work, with the employment of casual labour, and the consequent careless handling of inflammable materials, such as oily rags and paper. He insists, however, that to a large extent fires in printing works are preventable if only reasonable precautions are taken. He then proceeds to outline a few of these, beginning with the construction of a printer's building.

The ideal building from a fire, as well as from a manufacturing, point of view, is characterised as a ground floor structure built entirely of brick and steel, with concrete floors, and with the steel work cased in some fireproof material to prevent buckling in case of fire, but in the case of existing buildings which are the growth of a generation or more, and which are perhaps not so perfect from a fire point of view, he offers the following suggestions:—

Whenever minor alterations are made in a printing works, it is worth while for a printer whether he cannot by some slight extra expense improve his fire risk. The multiplication of match-lined partitions should be avoided. Instead of enclosing the lift well from top to bottom with match lining to keep out the draught, it should be enclosed in galvanised open wire guards, and if cold air is excluded from the ground floor, very little, if any, inconvenience will be experienced from draught on the upper floors. Whenever alterations are being made, it is worth considering whether partitions can with advantage be constructed in fireproof material instead of in wood; and when reglazing windows which overlook dangerous property the use of wired glass is also worth consideration. If a watchful eye is kept on the works carpenter, many possible fire spots can be eliminated. Spaces out of sight, in which will accumulate scraps of paper, oily rags, old boots, and fossilised fragments of lunches, should be blocked up so that no dirt can accumulate in them.

Every fire which has occurred in a printing works has had a small beginning, and a very large portion of them would not have occurred had greater attention been paid to cleanliness and order in a number of matters, each of which may appear in themselves comparatively trifling. Paper shavings and waste, instead of littering the floor indiscriminately, should be kept in proper receptacles and bagged at least once a day. Oily rags are notoriously liable to spontaneous combustion, and as long as they are required for use they should be kept in metal bins and the used-up rags burnt daily. Oil and grease should be kept in check by fitting drip trays under shafting hangers and by placing sheet zinc under all machines and upon benches where oils or inks are handled. If simple precautions such as these are insisted upon, and the few inexpensive appliances mentioned obtained, a hitherto dirty and untidy factory is in a short time transformed into a greatly improved fire risk, and at the same time an improved standard of cleanliness and order is set up which undoubtedly has a good effect upon the workpeople and the work produced.

Appliances for lighting and warming a building should be carefully considered from a fire point of view. Slow-combustion stoves, gas stoves, and similar appliances should be properly fixed in such a way that no wood work comes into contact with dangerously hot pipes. Swinging gas brackets should be carefully fixed, and all gas burners should be enclosed in wire globes. The use of flexible rubber gas piping is most undesirable. Flexible metal piping, connected at each end, not with rubber connections, but with proper screwed metal unions, should be used; moreover they are the cheapest in the end. Indiscriminate connecting of gas rings to ordinary gas burners is a very dangerous practice.

The use of matches should be strictly forbidden. Either electric lighters or wax tapers should be kept provided, and, in the latter case, a pilot for lighting the tapers should be kept constantly alight.

As to the importance of electricity as a cause of fire, provided care is taken that electric wiring and electric machinery are properly installed and maintained in good order, the risk of fire from them is very slight. On the other hand, if electric wiring is carelessly installed in such a way that cables are insufficiently insulated, or damaged by careless handling, short-circuiting, or partial breakdown to earth may occur, and thus set fire to the woodwork in the neighbourhood of the cables. Cleanliness is, in this connection as in most others, important. Users of electricity should beware of gradually increasing the load on electric cables by adding lights here and there or by substituting 32 c.p. for 16 c.p. or 8 c.p. lamps. Each individual addition is in itself trifling, but in the course of a year or two, without realising it, additions may be made which cause a serious overload on the wiring, causing over-heating, and consequent risk of fire. Paper should not be hung up to season close to the flexible wires of electric light. If a short circuit occurs in a flexible wire, the insulating material sometimes catches fire before the safety fuse has time to act, and this may easily set fire to any loose paper near.

Although printers may not consider it necessary to organise a private fire brigade amongst their workpeople, a few simple arrangements as to the duties of responsible people in case of fire should at least be made. Fire hose and water buckets must be looked to periodically, and chemical fire extinguishers specially should be tested at intervals. If a few people are made responsible for these duties, and an occasional fire drill, and possibly now and then a false alarm of fire be given, the chances of dealing with a fire promptly and effectually are greatly increased.

It is generally desirable to post in the works a few simple instructions as to means of exit, method of calling the brigade, and similar matters which need attention if a fire breaks out. If a night watchman is employed it is important to see that he clearly understands what to do under such circumstances, and his movements should be checked by a telltale clock. Perhaps the best method of keeping a night watchman awake is to give him some work to do. It cannot be too strongly insisted upon that there probably never was a fire in a printing works which could not have been extinguished without loss if a single bucket of water had been poured upon it at the right moment. Hence, any little time or trouble expended upon organisation of this kind is well invested.

Mr. Hazell concluded his paper with the following remarks on reduced insurance rates:—Discounts are allowed by the insurance companies for approved sprinkler installations with two water supplies, varying according to circumstances from 30 per cent. to 50 per cent. off the ordinary rate charged. With regard to automatic fire alarms, the insurance companies allow for them discounts varying from 10 per cent. to 25 per cent., subject to the insured providing them with an adequate supply of buckets and chemical extinguishers. It will generally be found that money spent on sprinklers or automatic fire alarms will yield in the shape of reduced fire premiums a good return on capital invested, apart altogether from their value in immensely reducing the risk of a serious fire.

Various trade insurance companies have been in existence for many years, most of which were started by members of the trade concerned. The most successful of these, such as the Millers, the Mutual Companies of New England, U.S.A., and others, have paid special attention to inducing the insured to lessen his fire risk by making improvements to his premises. The result has been that the average risk of fire in a trade has ultimately been greatly reduced, and as the companies are run for the benefit of the trade in question, the fullest possible reduction in rates has been allowed for all improvements made. The Printing Trades Insurance Company has just completed a most successful first year's trading. The company was launched under the auspices of the Master Printers' Federation, and as the capital and management are entirely in the hands of members of the printing trade, the company is virtually a mutual one. The company's surveyors, who are especially expert in printing risks, are prepared to advise intending insurers as to the best means of improving their premises, so as to reduce their fire risk and the cost of insurance, and it is anticipated that as the operations of the company are extended, great savings to the trade may be expected, and at the same time a good profit on the business may be earned for the shareholders.

Parliamentary powers having been obtained, the work of extending the Central London Railway from the Bank to Liverpool Street will be begun at once. The new line will provide for the first time a direct train service from Liverpool Street to the West End. A new subway is to be constructed giving additional access to the Bank station from the street, and the scheme includes the construction of a movable platform connecting the British Museum station of the Central London Railway with the Holborn station of the Great Northern, Piccadilly, and Brompton Railway.

THE GLASGOW FIRE. GENERAL VIEW OF THE RUINS, SHOWING THE EFFECT ON UNPROTECTED GIRDERS AND STANCHIONS.

The view shows the scene in Ingram Street after the fire had lasted ten hours.

THE GREAT FIRE AT GLASGOW.

The devastating fire which broke out shortly after midnight on August 17th, in the heart of Glasgow, and immediately opposite the headquarters of the City Fire Brigade, was first noticed in a stone building of four storeys, with a frontage of 80 yards in Ingram Street. The block of buildings destroyed was bounded on the west by the narrow thoroughfare of Shuttle Street, on the east by High Street, where the Cathedral stands, and on the north by College Street; the whole area occupied by the destroyed block consisting of about 6,000 square yards. Within the main building were the warehouses of twenty wholesale produce merchants, the wares including wines, stationery, boots and shoes, and pork. The Albion Halls, in College Street, the central meeting-place of all the trade organisations of the city, were reduced to ruins; and surrounding buildings, including the fire station itself, were in great danger, and had to be kept drenched with water to protect them against the intense heat. Within an hour of the first alarm, the top storey of the building in which the fire originated fell into the street, in which the mass of masonry, as shown in the accompanying illustrations, must have endangered the lives of the firemen as it fell, and must have greatly hampered their movements as it lay on the ground. The firemen were able to save the business premises on the opposite side of the narrow thoroughfare known as Shuttle Street, although the flames reached right across; but the Albion Halls could not be preserved, because, according to a local reporter, "the floors and fittings in the halls and rooms were all of wood." The affected portions of Ingram Street and College Street had each a frontage of 237ft., while the frontage to Shuttle Street was 198ft.; the average height of the blocks being 74ft. The buildings on this area were utterly destroyed within a period of about twelve hours from the first observation of the outbreak; the fragments that were left standing having to be at once demolished because of their extremely dangerous condition.

The handsome Central Fire Station had all its front windows broken, and was much damaged by fire and water. One curious incident was that a huge block of stone from the burning building opposite was hurled across the street through the window of the firemaster's office, and struck the wall on the far side of the room, smashing some pictures that were hanging there. The damage was at first estimated at £250,000; but the actual cost has been since assumed to reach about one-half that amount. Nevertheless, the fire is probably the greatest that Glasgow has ever known.

CANONS OF TASTE IN STREET ARCHITECTURE.

The Right Hon. James Bryce, British Ambassador at Washington, who is not only a distinguished publicist and man of letters, but has also a very pretty taste in the arts, was invited to address a convention of the National Academy of Art at Washington, and a portion of his speech dealt in a very interesting way with certain points of architectural interest. Mr. Bryce said:

I was asked, some days ago, to tell you what has been done in Great Britain in the way of bringing general canons of architectural taste to bear upon public buildings, and especially what statutes, or local regulations, existed preventing the unfortunate results which arise from erecting side by side buildings in different styles and of different heights, each marring the effect of the other. There was very little time to ascertain what our laws in Great Britain were on the subject. However, I wrote at once to a friend there, and I received, by cable, the answer which I expected, namely, that we have not got those statutes and regulations. This is very melancholy, because I should have been in a very strong position if I had been able to come before you and tell you what we had done in England, holding it up as a model for you! It would have been a beautiful thing for the old country, which claims to have done something in originating institutions which have been developed further in this country, if it had been able to pose as a leader and standard-bearer in the cultivation of art in its public aspects and in the bringing of legal weight to bear upon the artistic growth of cities! Unfortunately, that is not so.

I will tell you, Mr. President, as far as my recollection goes, what are the only ways in which we do incidentally prevent the disfiguring of cities by improper buildings, but, meantime, let me tell you that those who love art and taste in England, and in particular the organisations of architects themselves, have for a long time past been endeavouring to obtain some public regulation of streets and buildings. So far they have failed. They have failed for an obvious reason, which no doubt would be operative here also. They have supposed that regulations by public authority would infringe what are called the sacred rights of property. Now, property is a very good thing in its way, but property sometimes carries its demands a little too far, and that, because the right of ownership of a piece of land is vested in an individual he should therefore have the right to put up buildings, which may not only destroy the general beauty of a street or square, but may also destroy the beauty and effectiveness of buildings directly adjoining them which some man of better taste and higher public spirit has erected, with a view to the public enjoyment, as well as his own, would seem to be going a little too far. You may recall the words of Madame Roland at the time of the French Revolution, who said, "O, Liberty, what crimes are committed in thy name!" And I feel sometimes inclined, when I see the extravagant demands that are made in the name of property, to say, "O, property, what atrocities are justified in thy name!"

It seems unlikely that for some time to come we can, at any rate by public authority, secure that which we may call the censorship or supervision of the erection, style, design and size of buildings to be erected in streets and squares, which I understand the members of this association desire. But one must not despair of the future. After all, there is some progress marked by this mere fact that many more people desire the thing now than desired it formerly. There is, furthermore, this consolation, which we may apply to our minds, when we regret the absence of legal regulation—that if legal regulation had existed in former times we might have had things done which we should now regret. We might have had whole lines of streets, or large squares and circles built in styles which we should now think uninteresting and monotonous, merely because they represented the particular dominant taste and tendency of a particular time. Note, for instance, what was done by Baron Haussmann when he built so large a part of the great thoroughfares of Paris in the day of Louis Napoleon. Most of us would now feel that those long lines of boulevards are monotonous and, indeed, many people would call them dull and soulless. Certainly there is far too much of that sort of thing in Paris. That was the style of the time. Haussmann was able to carry out the ideas which he, or somebody else for him, endeavoured to apply, and the consquence was that the picturesqueness and charm of old Paris vanished. A great many of its quaint, winding streets, which carried one back to the days of the Renaissance, and which we would gladly have preserved, then made way for the tame and conventionally ornate, but essentially wearisome, style which Haussman applied to those great Parisian thoroughfares.

We cannot be too sure that something of the same kind would not happen again; and, therefore, perhaps, we must not too much lament the unchartered freedom, the unqualified and absolute license which is now enjoyed, because it, at any rate, does preserve a certain measure of variety. And when taste grows better it may be that everyone putting up a building in a street will think a little more than he has hitherto thought of its harmony with the adjoining buildings.

As you know, there is one difference between the condition in London and the condition here. In your American cities, as a rule, the man owns his own land and puts his own house upon it; or even if the builder builds the house upon speculation and afterwards sells it, it is generally not done in large stretches of houses. In London, on the other hand, the existence of large estates, each owned by a great landlord, has led to the erection of long stretches of houses, sometimes perhaps half a quarter of a mile or even a quarter of a mile, all upon some uniform plan. The architect of the estate controls the whole affair, and what is erected follows the designs he suggests or approves. You have not that here, and therefore you see the results in the fact that in London many of the streets belonging to these large estates are exceedingly monotonous, and such streets as Gower Street or Harley Street, for instance, are as dull as can be. Here, and in Washington, in particular, on the other hand, you have the very opposite extreme. Everybody does what is right in his own eyes. He builds his own house in his own way, and you very often have the most incongruous styles or sizes close together. At the same time you have a certain amount of variety, which, on the whole, is better than dreary uniformity.

On Monday last, when the House of Commons went into committee on the Housing and Town Planning Bill, Sir F. Banbury, moving the omission of the clause which makes Part 3 of the Working Classes Act, 1890, compulsory, declared that this made the President of the L.G.B. a sort of emperor; a kind of Julius Cæsar, who of his own sweet will should direct the destinies of his less fortunate fellow subjects. Mr. Burns replied that the clause had the exactly opposite effect!

THE GREAT FIRE AT GLASGOW.
These views show the effects after the fire had lasted twelve hours.

Societies and Institutions.

Architectural Association School of Architecture.

The "Curriculum" of this school for the session 1909-10 forms a booklet of seventy-eight pages, to say nothing of the advertisements. The master, Mr. H. P. G. Maule, F.R.I.B.A., is assisted in the Day School by Messrs. H. A. Douglass, A.R.I.B.A., L. M. Gotch, A.R.I.B.A., H. L. Samson, Alan Potter, Alan L. Snow, and Guy Church, A.R.I.B.A. Mr. Ernest Newton, F.R.I.B.A., has been appointed by the Board of Architectural Education to act as special visitor, and will keep himself in touch with the work of the school, and confer with the masters from time to time as to the progress made and the methods adopted. The Master of the Evening School is Mr. C. E. Varndell, A.R.I.B.A., who is assisted by Mr. A. C. Dickie, A.R.I.B.A., and Mr. J. B. Scott, with about a dozen lecturers and instructors. Syllabuses, time-tables, lists of text-books, and dates of meetings of the Architectural Association are included in the booklet, for which application should be made to the secretary, Mr. S. G. Driver, F.C.I.S., 18, Tufton Street, Westminster.

Committee on Ancient Earthworks.

The Committee on Ancient Earthworks and Fortified Enclosures (chairman, Lord Balcarres, M.P.; hon. secretary, Mr. A. G. Chater, 41, Porchester Square, W.), have favoured us with a copy of the report prepared for presentation to the Congress of Archæological Societies held in July. The Committee report a steady growth of interest in ancient fortifications, as shown by measures taken for the preservation, exploration, and recording of these remains. It is noticed, however, that many large areas, such as Buckinghamshire, Norfolk, and Surrey, are still neglected. A Royal Commission on Welsh monuments was appointed in August, 1908, and in October, 1908, the Government appointed a Royal Commission to make an inventory of the ancient and historical monuments of England, and to specify those which seem most worthy of preservation, while a sub-commission has been appointed to deal with earthworks and pre-Roman remains. The county of Hertford is now being surveyed, and other counties will follow in turn. The officers in charge of the revision of the Ordnance Survey on the scale of 25ins. to the mile have agreed to keep the Committee informed of the position of their field parties, in order that any earthworks hitherto omitted or insufficiently shown may be made good in the next revision. Many instances of preservation, of destruction, and of exploration are chronicled; and under the second of these sections it is mentioned that many instances have been noticed of the mutilation of ramparts and ditches through the utilisation of ancient earthworks in the laying-out of golf courses, and that this practice is apparently increasing; the destruction being in most cases due, apparently, to ignorance of the scientific value and historical interest of the remains. Another *bizarre* incident was the mutilation last year of the walls of the hill fortress at Conway Mountain by Territorials, who entrenched themselves behind the walls. Quarriers and road-menders have shown similar disregard for the monuments of antiquity. Among the interesting items recorded as to exploration, it is mentioned that in the spring of the present year the Society of Antiquaries conducted an exploration on the site of Christ's Hospital, under the direction of Mr. Philip Norman, LL.D., and Mr. Francis W. Reader, with the object of finding remains of the angle bastion of the city wall, where the latter, after running due west, turned southwards in the direction of Newgate. A considerable portion of the north side of the bastion was uncovered, together with a piece of the city wall. The latter showed masonry of the same character as in other parts of the wall that have been examined; and the bastion proved to be of later date than the wall itself. Signs of an external ditch were looked for, but the indications were those of a running stream at the foot of the wall. The important excavations at Corbridge, at Maumbury Ring, and others elsewhere, are also noticed, and a bibliography of the year's literature on the subject is appended.

Birmingham Municipal School of Art: School of Architecture.

A Day School of Architecture has been founded at the Municipal School of Art, Birmingham.

The object is to provide architectural students in the Midlands with a thorough training in all the branches of their profession, and to prepare them for the examinations of the Royal Institute of British Architects.

The school course will be spread over four or five years. It is intended that the first two years shall be spent at day classes, and that they shall take the place of the first two years of articled pupilage. The latter two or three years will be spent at evening classes, and will run concurrently with articled pupilage.

The syllabus will be as follows:—First year: Lectures on architectural history, building construction, elementary physics and geometry; demonstrations and practical work in stone-masonry, carpentry and bricklaying; simple planning, elementary design (doors, roofs, windows, etc.); perspective; drawing and lettering. Second year: Studies in ancient architecture, including measuring; practical work; lectures on the historic styles and on iron and steel construction, physics, etc.; design. Third and fourth years: Mainly design and advanced physics and kindred subjects. It is hoped that third and fourth year students will be able to take some of their science subjects and carry out tests as to strength of materials, etc., at the Birmingham University. The machinery and equipment possessed by the University for this purpose is quite unique.

The teaching staff is as follows:—General director, J. L. Ball; assistant director and lecturer in design, E. F. Reynolds (Sloane Medallist, 1903); lecturer in history, W. H. Bidlake, M.A., A.R.I.B.A. (Pugin Scholar, 1885); lecturer in physics, etc., F. B. Andrews, A.R.I.B.A., assistant, John B. Surman, A.R.I.B.A. The school will meet daily, from 9 to 5 (Saturdays, 9 to 1), and the first session will commence on Monday, September 13th, 1909.

It is anticipated that students who follow the full course will be exempted from the Intermediate Examination of the R.I.B.A.

Further information will be supplied upon application to Mr. A. H. Leaney, secretary.

Our Plate.

Vicarage in the English Lake District.

The plans and perspective drawing show the first design for the new vicarage at Winster. The cost had to be reduced somewhat, and this led to a slight modification of the plans before the work commenced.

The house occupies an elevated site on the eastern slopes at the head of the Winster valley. The ground falls rapidly from N.E. to S.W. Rising ground and plantations afford a protection from the cold N. and N.E. winds; from all other points the views over hill and valley are very extensive, with, in the distant south, glimpses of Morecambe Bay (fourteen miles away).

The main drive approaches from the S.E., and the carriage court forms a wide terrace enclosed by walls of local stone with a wide flight of steps descending to the tennis lawn. The western terrace is a continuation of this, but is much less in width.

The whole of the walls are of local stone from a quarry adjoining. The house is roughcast and whitewashed externally, and the roof is covered with Westmorland green slates.

The windows, external doors, and main stairway are of English oak; the whole of the remaining joiners' work is of best yellow pine, painted white throughout the private portion.

The whole house is lighted with Cox's patent air gas, installed by Messrs. J. K. Thornborough and Co., of Windermere.

Mr. Joseph Braithwaite, of Windermere, is the general contractor. Messrs. Doulton and Co., have supplied the sanitary fittings.

Mr. W. L. Dolman, of Windermere, is the architect, and the pen-and-ink perspective drawing is by his brother, Mr. Lewis J. Dolman.

House on Boyle Farm Estate, Thames Ditton.

This house has recently been erected on the historical estate of Boyle Farm at Thames Ditton. It is built of local red sand-faced bricks, and half timber work, left rough from the saw and plastered smooth between the timbers. The roofs are covered with red sand-faced tiles. The accommodation provides dining-room, large drawing-room, lounge sitting hall, and the usual offices on the ground floor, and five large bedrooms, and bath-rooms on the first floor.

The architect is Mr. A. Jessop Hardwick, F.R.I.B.A., of Eagle Chambers, Kingston-on-Thames, and the contractor is Mr. S. Hurst, of Chiswick.

Our Illustrations.

Houses near Golder's Green.

The houses shown on p. 163 are typical of a series of buildings, both detached and semi-detached, to be erected near Golder's Green by Messrs. Spiers and Son, of St. John's Wood. No two sets of plans are alike, some being a little unusual in arrangement, but all elevations suggest the same period. The facings are Luton bricks, with red sand-faced long-and-short work, and red rubbed arches. Black sand-faced roof tiles are to be used throughout. All the joinery work is painted deal, except the front doors, which are mahogany. The halls are all tiled with black and white marble, the entrances in front gardens with old York paving, and the gates are of wrought iron. The architect is Mr. John W. Rhodes, Mitre Court Chambers, Temple, E.C.

Six Labourers' Cottages, Heath End Bucks

In these cottages, which were built for Mr. O. A. Keane, Wycombe, the accommodation comprises four rooms in each, with coals, stores, pantry, etc., and a small bath in scullery is provided. The bricks are local made reds and purples. The walls on the ground floor are 11¼ins. hollow, and 9ins. with lime rough-cast. Brick-on-edge coping and tile creasing roof are to be covered with hand-made tiles, and large ornamental W.I. brackets support the gutters, with wide projection to the eaves. Earth closets are to be fixed, and the rain water is to be run into large oak butts. All external woodwork (except sashes, doors, and frames) is to be left rough, and treated with solignum. The estimated cost is £798.

White City Exhibition Building.

This building has recently been erected in the Machinery Hall, Stand 49, at the Imperial International Exhibition, Shepherd's Bush. The walls are constructed inside and out with fibro-cement slabs, with a perfectly plain surface, which can be treated in any decorative way desired. It is roofed with Buttermere green slates in diminishing courses, the chimneys, where emerging from the roof, being rough-casted. The living-room, with its old-time ingle-nook, roofed over at 7ft. from floor, open timbered ceiling, and other features, is noteworthy. The cost of the building erected anywhere in England is £236 in client's foundations. The contractors are the Alnwick Foundry and Engineering Co., Alnwick, and 52, Queen Victoria Street, the architect being Mr. Andrew Sell, 3, Howick Street, Alnwick.

Messrs. Henry Lovatt (Limited), of Wolverhampton, have secured the contract for the erection of new barracks for the Egyptian Government at Abbassia, near Cairo. The barracks will take three and a half years to build.

Hardships of Tendering.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—I was much interested in your article in the Journal for August 25th, headed "Hardships of Tendering," and consider your suggestion, "that the tender to be accepted should not be the lowest, but that which approximates most closely to the mean of all the tenders received," is a most excellent one, and ought to receive serious attention from architects especially.

In most cases the great difference between the top and bottom tenders ought to convince the architect that there is something seriously wrong, and he should hesitate to advise his client or committee, as the case may be, to accept a tender which is so obviously underpriced, as in all probability he has worked out a rough estimate of the probable cost before asking for tenders.

Some time ago I tendered for a considerable contract in my department. The work had all to be done to a carefully prepared and stringent specification, and the names of the firms whose goods had to be used being given, all the competitors were upon the same basis, and it was simply a question of the margin of profit.

On looking over the list of some 20 tenders, most of them from well-known firms, it was evident that there was a serious error in the amount of the tender at the bottom of the list, which was accepted.

On comparing this sum with my own prime cost, I found that it just represented the value of the material! The sequel showed the unwisdom of accepting an abnormally low tender.

It is well known that many architects do advise their clients to accept the tender which in their opinion most fairly represents the value of the work which they propose to put into their building, and which is likely to reflect credit upon themselves, and give the utmost satisfaction to their clients, and if this custom could be applied more generally by the profession, we should hear less about shoddy materials and scamped workmanship.

HEATING ENGINEER.

London, S.W.

Is Joinery a Declining Trade?

To the Editor of THE BUILDERS' JOURNAL.

SIR,—Is joinery a declining trade? is a question that more than one craftsman of the present day asks himself, and does not fail to point to the introduction of machinery as one of the principal causes of such depression. Let that joiner or builder, or architect, whatever he may be, answer satisfactorily to himself the further question, has machinery ruined any trade? Has it ruined the cotton trade, the iron trade, or, indeed, any manufacturing concern?

It may possibly have diverted it for a time into other channels; I have often heard it stated that machinery has spoilt all artistic feeling as regards woodcraft. Surely this is erroneous. There can be no need of art and beauty being destroyed by the labour being lightened; for that is the chief idea of employing machinery. The design should not be made to fit the machine, but the machine employed to carry out the design. This chronic misuse of machinery is not so much amongst the large firms as by the little builder. I will quote from my own experience of such.

We will say our builder has just taken to the idea of machinery in his shop. He has purchased, say, a circular saw, planer, and moulder combined, and a band saw. More than likely, where these were bought, he was shown in how many minutes (or how few) a door stile could be planed true. He saw the circular saw ploughing its way through a batten or deal. He listened to the eloquent tongue of the seller. Naturally he goes home fancying he knows all about it, and dreams of future work being done at lightning speed. Oh that speed! It is that that is the cause of all bad work, machine or hand. Well, the machines being sent home, and fixed, all in good working order, he next thinks of who will work these new friends of his. Most likely there is about his yard a handy labourer, clever at anything. "Just the fellow for the circular saw," says our builder; for what skill is required to push a log? Perhaps not, Mr. Builder. Very likely he will be more pushing than skilful. For such a man as I am speaking about pushed so forcibly on a saw I was working beside once, that he broke the belt, and thus caused a delay, much to his own surprise.

To return to our machine shop. Our friend now thinks of the planer. Ah! there is a joiner in the shop—perhaps not superb at bench work, but he'll jog along all right on the machine, because the machine does the work, not he. And so on goes our builder, plunging onward, finding machinery does not pay so well as he expected. Saws run; spoil materials. Planer will not work true. Tenons all want easing by hand. Work requires extra cleaning up. And the engine—certain to be a gas engine, which the makers assured him required no attention—this will soon start playing pranks, suddenly stopping for no known reason. This being Master Knowall Jack's job, he starts unscrewing and fiddling. Very likely his master helps him at this important job. Perhaps between the two they make a little improvement; but at any rate troubles have begun, for the newness has worn off. Saws are not so perfect. Planer knives are thick, and our scrap mechanics do not know how to regulate these things.

Now if (always an if) our builder had in the first place employed a skilled expert, his machines would still be running at their best, and the output would be as high as possible. Not that I intend to say joiners are not machinists, for I always contend no man is more suitable for machine joinery than a skilful hand joiner. Still, however, he cannot expect to jump to the top of the tree at one bound. It has ever been my advice to present-day workmen to study machinery at every opportunity, for it seems that in the near future every carpenter or joiner will need to be as thoroughly conversant with machines as with hand tools. Not that hand labour can ever be entirely superseded. That is well nigh impossible. But they will have to equip themselves with a thorough all-round knowledge, and so study their machines that they know exactly what can or cannot be done on them. For instance many a joiner still thinks nothing can be done on a circular saw save ripping and perhaps a little cross-cutting. Never so much did he deceive himself, for that useful tool can be made to perform many a helpful operation in joinery; so likewise will the band-saw, although this is not so tractable to workshop rigs as the circular. Still, with the machines previously mentioned, it is possible to perform well nigh everything required in an ordinary joiners' shop. If space and funds will allow, it is far better to have separate machines than a universal woodworker. As far as they go, the universals are admirable machines, but at some time or other the circular will be wanted in a hurry just in the middle of a moulding job, and it is no joke resetting cutters for the same job.

So long as craftsmen, employers, as well as employees, look to the future of their trade, and adapt themselves to present-day requirements, there will be no fear of a decline. At present the building trade is undergoing a metamorphosis, after which no doubt it will burst out into a beautiful future. At least, this is the hope of the writer.

Arthur Castle.

Proposed New Works.

ACTON.—For purposes connected with its new public buildings, the Council has decided to apply to the Local Government Board for sanction to borrow £2,200.

BRIDLINGTON.—The proposal to widen the north end of St. John Street at an estimated cost of £670 11s. for street works only, has resulted in an application to the Local Government Board for sanction to borrow £3,400.

EPPING.—The Epping Guardians propose to erect temporary buildings at the workhouse to meet the increased pressure on the infirmary accommodation.

LIVERPOOL.—The Lancashire Asylums Board have recommended the adaptation of Seafield House for the accommodation of 345 patients, and the extension of Whittingham Asylum. The alterations at Seafield House are estimated at £14,500 or £42 per bed.

LLANDRINDOD WELLS.—A special meeting of the Urban District Council has been held to consider a letter from the Local Government Board relative to the Council's application for a loan of £10,000 for the purpose of the erection of a pavilion in the recreation ground. The Local Government Board wrote stating that whilst they saw no objection to the erection of a pavilion, they could not sanction a loan of £10,000 for the purpose. Mr. John Burns has confirmed the decision given in the Local Government Board's letter and has very strongly insisted that there should be "no frills." The Council has accepted the decision, and a modification of the scheme is under consideration.

LONDON.—The cost of a new recruiting depot, which it is proposed to erect between Great Scotland Yard and Craig's Court, Westminster, is estimated at between £25,000 and £30,000.

SOUTHPORT.—The plans of the new theatre have been before the Plans Sub-Committee of the Highway Committee, but have not yet received the approval of that body. Mr. Bertie Crewe, of London, who for many years was with Mr. Frank Matcham, is acting as joint architect in the present scheme with Mr. G. E. Tonge, of Southport.

SUTTON-COLDFIELD.—The proposed new post-office buildings to be erected on the site of the old Emmanuel College Arms Inn, Mill Street, comprise, on the ground floor a public office, a sorting room, sub-postmaster's office, postmen's, messengers' aid lady-clerks' rooms, and cycle and truck sheds. On the first floor house accommodation is provided for the sub-postmaster. The elevation to Mill Street will be carried out with stonework to the ground floor storey, the upper part being of red brick with stone dressings, surmounted by an ornamental stone entablature and balustrade. Messrs. Essex and Goodman are the architects.

Works in Progress and Completed.

ASHBOURNE.—The Duke of Devonshire recently performed the ceremony of opening the new buildings of Queen Elizabeth's Grammar School. The old Grammar School, which is now superseded, obtained its charter from Queen Elizabeth in 1585, but there is evidence that the institution itself dated a good many years further back. The idea of considering a plan for extending the old school was abandoned when the Governors were advised by the Board of Education to make provision for the education of girls as well as boys. The new buildings were designed by Mr. E. M. Longsdon, F.S.I., M.R.S.I., Bakewell, and the builder was Mr. W. Thorley, of Noding. There is accommodation for about 180 scholars, and without difficulty 200 could be received.

BOTHWELL.—A boom in the building trade appears to be in progress in this district, there being at present in course of erection a large chapel school for the R.C. community of Bothwell and Hamilton Palace Colliery districts, the probable cost being £8,000. The plans, which were prepared by Mr. W. Orr Watson, architect, 95, Bath Street, Glasgow, not only show the large chapel school now in course of erection, but also the opening up of a new street, and the erection of a chapel and presbytery on the adjoining ground. The contractors for the mason work are Messrs. Robert Park and Co., Motherwell, and for the wright work, Messrs. Allan and Baxter, Glasgow. An addition to the Convent at Bothwell for the accommodation of the local priest is also in course of erection.

In contiguity to the fountain, Bothwell, a group of buildings to be known as the Donald Institute is being erected.

Owing to the abnormal growth of Bothwell Haugh, school accommodation has been found to be quite inadequate, and schedules have been issued for the erection of a second school. The work will be proceeded with at once. The architects are Messrs. Bruce and Hay, Glasgow.

A petition has been presented to the Bothwell School Board to erect a school at Bothwell Park, a large colliery district midway between Bellshill and Uddingston.

A new school for the Dykehead and Udston districts of Hamilton was opened recently.

BURNLEY.—The site of the new technical school erected in Ormerod Road, Burnley, to be formally opened on September 11, covers an area of about 10,000 yards. The purchase price of the site, which was acquired from Sir J. O. S. Thursby, Bart., was £5,296; and when completed it is estimated that the total cost of the building will be £50,000.

CARR-BRIDGE.—The United Free Church which has just been opened here, has cost £1,600.

DONCASTER.—The Doncaster Race Committee have just had erected an additional stand and enclosure at a cost of £5,960. The plans and specifications were prepared by the Borough Surveyor, Mr. F. O. Kirby, and the contractors were Messrs. Mullins and Richardson, builders, of Doncaster. Mr. W. Booth acted as clerk of the works.

DOVER.—The great marine Continental station, which will involve a sum of £1,000,000, is now being erected. The new station will have special accommodation for mails, and everything required for the comfort of passengers. Work has also been started on a great landing-stage, large enough to accommodate two Atlantic liners at once, and it will probably be ready by next spring.

GLASGOW.—The Dean of Guild Court has given permission to the erection of buildings in connection with the reconstruction of the Glasgow Royal Infirmary. The plans which have been passed pertain to the Castle Street portion, which is estimated to cost about £89,000. When these buildings are erected, about one-half of the new scheme will have been completed. Other linings that have been passed at the Court include the following:—Glasgow and South-Western Railway Company, to erect dwelling-houses and shops in Howard Street and Stockwell Street; Andrew Anderson, builder, to erect four tenements of dwelling-houses in Laverockhall Street and Auchentoshan Terrace, Springburn; the Glasgow Magdalene Institution, Maryhill, to take down buildings in Lochburn Road, and to erect new buildings; J. and J. Fraser, to erect two dwelling-houses on the lands of Burnbank, East; A. and R. Bryson, dairymen, to erect tenements and other buildings at the corner of King Street and Claythorn Street; Archbishop Maguire, and others, for the Roman Catholic Church, Govanhill, to erect a church and clergyman's house in Dixon Avenue and Belleisle Street, Govanhill, at an estimated cost of £15,000.

GORLESTON.—The Primitive Methodist new church upon which work is now proceeding, supersedes an iron structure which has served as a place of worship for over 14 years. Mr. B. G. Beech, of Yarmouth, is the builder.

GRIMSBY.—The new extension which has recently been made to the Welholme School, and which will accommodate an additional 500 children, was opened recently. The extensions occupy what was a vacant space between the boys' and girls' department, and consist of two storeys with four class-rooms on the ground floor, and four on the first floor. Four of these are for girls, with accommodation in each class-room for 50 girls, and four are for boys with an equal accommodation. There are also new additional class-rooms for infants, with school places for 100, a new laundry department, with cloakrooms and latrines. The old buildings have been entirely renovated and brought up-to-date. The architect is Mr. H. C. Scaping, and the builder Mr. H. Marrows. The total cost of the school amounts to over £18,000.

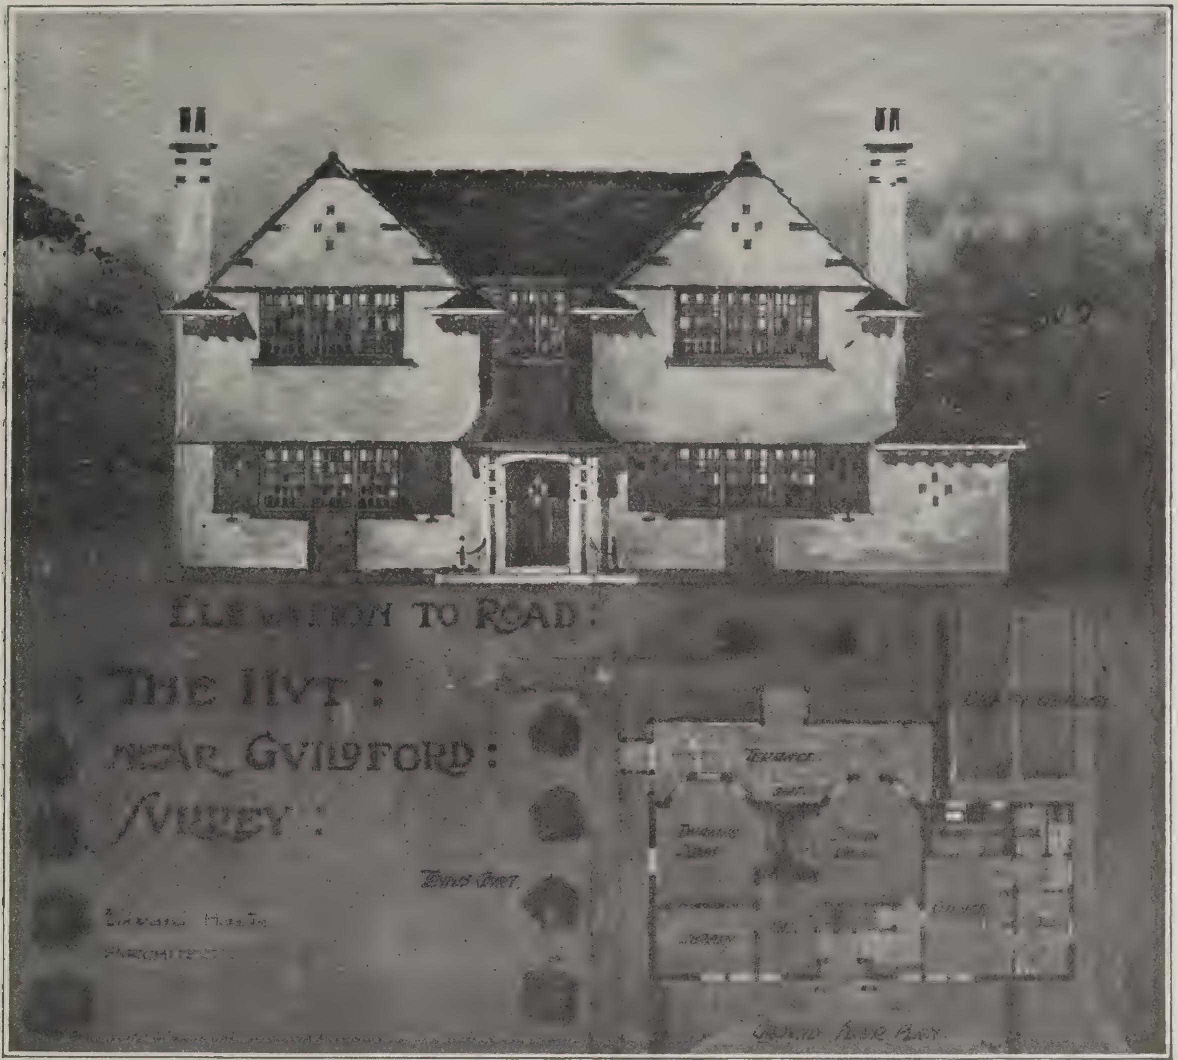
LEES. — The new District Council premises, which have just been opened, and which were the late offices of the Christian Brethren Chapel, have been thoroughly overhauled, and adapted to the requirements of the authorities.

LONDON.—The demolition of Holy Trinity Church, Kingsway, W.C., has been authorised by the Consistory Court. The walls of the church, which was built in 1831, began to crack soon after the construction of Kingsway was begun, and the building has now become unsafe. A new church, seating 800, is to be built, and £7,500 has been raised towards the cost of £8,000.

MANCHESTER.—The Corporation baths, which have just been opened, occupy an area of 3,173 square yards. The males' first-class, with 41 dressing boxes, is 75ft. by 28ft.; the second-class, a little wider and the same in length, with 49 dressing boxes. The baths for females, used as first and second class, is 66ft. by 25ft., and has 49 dressing-boxes. Of the wash baths there are in all 65.

NEWBURY.—The foundation stones of an additional block of municipal buildings which are being erected on part of the site of the old Georgian town hall, demolished a few months ago for the purposes of street improvements, were laid recently.

PETERHEAD.—The extended buildings at the Peterhead Academy, which were opened recently, have been built at a cost of £8,000. Every requirement that the educational needs of the town have rendered imperative, has been catered for. The architect is Mr. Arthur Clyne, F.R.I.B.A., Aberdeen.



"THE HUT," NEAR GUILDFORD, SURREY. EDWARD HASTIE, ARCHITECT.
This house may be regarded as an excellent example of the dignity of simple masses and symmetrical composition.

Mr. Alexander Hay, Peterhead, has acted as clerk of works. The following is a list of the chief contractors:—Mason work, Messrs. Findlay and Henderson, Aberdeen; (the following gentlemen are all of Peterhead): carpenter work, Mr. James Taylor, jun.; plumber and gasfitting work, Mr. John Ferguson; slater work, Mr. James Greig; plaster work, Mr. William Shand; painter and glazier work, Mr. Alexander Ferguson; steel and iron work, Messrs. Milne and Robb; heating installation, Mr. R. Tindall, Aberdeen.

PRESTON.—A plan and estimate referring to the laying out of Haslam Park, having been submitted to the Parks and Baths Committee, it has been recommended that application be made to the Local Government Board for sanction to the borrowing of £6,000, this being the estimated sum necessary for the satisfactory execution of the work.

RETFORD.—The new mission room, the foundation stone of which has just been laid, is, including the land, estimated to cost about £500. Seating accommodation for upwards of 300 people will be provided. The contractor is Mr. Frank Fenton.

SHEFFIELD.—Rapid progress is being made with the new Post Office, work upon which commenced about two years ago. The instrument room is virtually finished, and is about 70ft. broad and 160ft. long, well ventilated, and lit by numerous and spacious windows. Work on the ground floors is not so far advanced, on account of the stonecutting machinery having been placed there, but it is now being pushed forward with great rapidity. It is intended that part of the building shall be ready for occupation at Christmas. This section is at the rear, and comprises an enlargement of the sorting office in Flat Street, which will then afford more than double the present accommodation. The rest of the structure will be opened a year hence.

TOXTETH.—The two important blocks of buildings which have recently been added to the Workhouse, are to serve as mental hospitals for 200 males and 100 females. The complete cost of both buildings, including furnishing fire mains, hydrants, and heating, is about £20,000, or equal to £70 per bed. The architect is Mr. Walter W. Thomas.

WALLSEND.—That portion of the parish scheme which, owing to lack of funds, cannot at present be carried out in its entirety, now in course of erection, comprises the following: The parish hall, an apartment 52ft. long by 31ft. wide, a ladies' parlour, a large class room, and a spacious lobby. The part that has been postponed includes a small hall to accommodate about 100 persons on the ground floor. The contractor for the general work is Mr. John Lant, Tyne Quarry, Walker Road, and for the plumbing work Mr. Thomas Hedderley, of Wallsend. The architects are Messrs. Frank Caws, Steele, and Caws, Sunderland.

WEARHEAD.—The foundation stones of a new Wesleyan Church were laid recently. Mr. Reed, of Fosterley, is the contractor for the building.

WEST BRIDGFORD.—The foundation stone of a new masonic hall has been laid. The main front of the building is to face the river, and a balcony will afford a pleasant view of the reach between Trent Bridge and Wilford Bridge. The main features of the building will be banquetting, lodge, and club rooms. Mr. A. E. Lambert, who is a Brother of the Lodge, is the architect.

PAINT FOR "TOP COATS."

Having dealt with the foundation coat, it is important to determine the chemical and physical properties of each subsequent coating. The difference between the successive coats should be gradual, so as to form a layer which, starting upwards, becomes more elastic as it approaches the finishing coat.

As to the character of the pigment that should be used with the linseed oil varnish for making paint for use as top coats the pigment used must be practically both chemically and physically inert; more important still, it should be in a fine state of division, and form a perfectly homogeneous product which can only be obtained by repeated grinding.

One of the principal functions of the solids in paint is to protect the dried binder from destructive influences. Some substances, by reason of their stable nature, possess this property in a high degree—they do not act chemically upon the oil, and are not easily changed. They are classed as inert pigments, and should be used simply as a means of improving and increasing the durability of the paint.

Regardless of colour, there is no *one* pigment that will "answer all requirements, fill all the offices" of a perfect pigment to mix with the linseed oil varnish for paint making, not a single one that will do what pigments must do, until an ideal binder is found to mix with it, that will retain it and prolong the life of the paint.

Certain solids, under certain conditions and in certain proportions, have mutual action upon each other; they inter-change elements and combine to form new substances.

In Parliament.

By our Gallery Representative.

The Valuation of Sites.

Mr. Ridsdale asked the Prime Minister whether the Government had consulted any professional land surveyors or land agents as to the cost of valuing the whole of the land of the United Kingdom; if so, whether any of the gentlemen consulted had had any particular experience in the valuation of land on the assumption that it was deprived of the improvements attached to it; and, if so, whether he would lay before the House a summary of the information received from those gentlemen, including any records they might have communicated to the Government of actual sales either by private treaty or public auction of site values as defined in Clause 14 of the Finance Bill.

Mr. Hobhouse, who replied, said:—The answer to the first and second parts of the question is in the affirmative. As regards the last part of the question, my right hon. friend does not see his way to accede to my hon. friend's request.

The Piccadilly Hotel.

Mr. Ashley asked the Prime Minister if his attention had been called to the statement with respect to the Piccadilly Hotel (Limited), now in liquidation, that alterations in the designs of the building were insisted on by the representatives of the Crown, as landlord, which entailed an expenditure of about £160,000, and a further large loss owing to the diminished rental of shops sublet in the building; and whether it was proposed to continue this system.

Mr. Hobhouse, who replied, said: I have seen the statement referred to, but there must, I think, be some mistake in it, as I am advised that the Crown requirements, which were in the main settled by the previous Government, could not in themselves have entailed the extra cost or loss in rental alleged. It is clearly desirable that, in the case of large rebuilding schemes on Crown property, due regard should be paid to the architectural result, and I am not prepared to say that a slight additional expense is not sometimes justified for this purpose. At the same time, I can assure the hon. member that care is taken that commercial considerations are not overlooked; indeed, I am at the present moment considering the best method of securing these two objects in another important rebuilding scheme.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himself of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable; and it must be understood that both question and reply will, as a rule, be published in these columns.

Freart's "Parallel of Ancient Architecture."

STAMFORD. PARALLEL.—In reply to this correspondent, Mr. Batsford, bookseller and publisher, 94, High Holborn, W.C., to whom we submitted the question, states that Freart's "Parallel of Ancient Architecture with the Modern" has very little value (only a few shillings).

WIMBLEDON.—T. S. writes: "Please name a building in Rome, with an imposing facade, suitable to measure for the R.I.B.A. Final. It must be easily accessible, and able to be measured quickly. Is there any difficulty about obtaining permission to measure such a building?"

T. S. will be most unwise if he visits Rome without first reading Anderson's "Architecture of the Renaissance in Italy," and a selection at least of the books mentioned therein, which should enable him to judge for himself as to what buildings would be most suitable to his purpose. If his time is short he will be better advised to measure completely a comparatively small building, such as Bramante's Tempietto in the Cloisters of San Pietro in Montorio, rather than to make a hasty drawing of an "imposing facade," such as the Farnese Palace. He should provide himself with the R.I.B.A. travelling card (see current Kalendar), and get it *visé* by the Italian Consul before leaving this country. Architectural students are so usual in Italy, that they are apparently tolerated with a fairly good grace, and difficulties are not as a rule great. G.

Constructing Large Rainwater Tanks.

SLOUGH.—W. R. M. writes: "Please state whether the walls of the rainwater tanks shown in the accompanying sketch (not reproduced) are of sufficient thickness."

The proposed method of constructing rainwater tanks with thin brick walls and cast-iron struts is not at all desirable, as the iron would rust very rapidly in such a position. This is a case where reinforced concrete walls would be very suitable, and application to any of the recognised concrete specialists would enable you to construct an economical and lasting pair of tanks. If the brick walls must be used, then brick arches from pier to pier would be more effective than cast-iron beams. HENRY ADAMS.

The [London] City Engineer, in his annual report, alludes to the various subways for pedestrians provided in the City. The work of constructing subways at Blackfriars Bridge, which would shortly be completed, would cost about £30,000. It would be provided by the London County Council in co-operation with the City's action in widening Blackfriars Bridge. A proposal to construct a subway beneath Bishopsgate Street at its junction with Liverpool Street was considered but not adopted, as the police effectively regulated the traffic at that spot. There were in the City subways of a total length of one mile and 947 yards. The total length of mains and conduits in subways was 13 miles 999 yards. This return does not include certain subways under the control of the London County Council or the Central London Railway Company's subways at the Mansion House, or the subways under private thoroughfares. Various subways have been permitted to be constructed to connect premises occupied by the same persons on either side of streets, and an annual charge is made for each, except when special circumstances prevail.

* * *

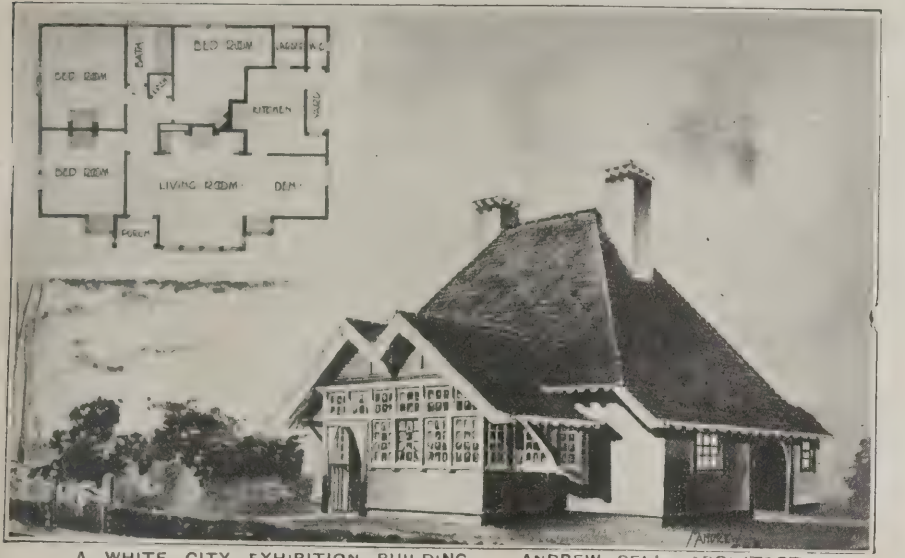
A month ago the members of the Main Drainage Committee of the London County Council paid their annual visit to the outfall works at Barking and Crossness. Since then many members of the Council have expressed a desire to examine the main drainage outfalls, and arrangements are therefore being made by the officials to conduct parties of councillors, during the recess, to the works. The members will be conveyed down the river in the steam yacht Beatrice. Arrangements are also to be made to enable some of the councillors to travel on one of the sludge vessels, in order that they may have an opportunity of seeing the manner in which sewage sludge is finally disposed of.

Federation News.

SHEFFIELD ASSOCIATION.
Secretary: T. Smith.

At the monthly meeting of Sheffield Association, the suggested form of sub-contract submitted by the Yorkshire Federation formed one of the principal subjects of discussion, the points involved being so drastic, and so contrary to local custom, that it was deemed advisable to relegate the further discussion to the Emergency Committee, who subsequently discussed the matter at very considerable length. It was held that it was fair and reasonable that a principal contractor should give notice to a sub-contractor of his intention to apply to the architect for a certificate, though there was a strong opinion held by many members that the sub-contractor had no right to interfere in matters between the principal contractor and the architect, as the sub-contractor had his remedy against the principal contractor, by whom he was solely employed, and as such was not a party to the contract. The further clause giving the sub-contractor the power to terminate forthwith his contract and bring an action against the principal contractor for labour and material to date if the principal contractor omitted within two days of the receipt of a certificate to advise the sub-contractor of the receipt of such certificate was considered to be beyond all precedent, likely to cause litigation and altogether unreasonable, and the committee unanimously decided to refuse absolutely to consider such a clause in any shape or form. The committee also objected to a clause absolutely exempting the sub-contractor from any contingent liability in a case where a claim for compensation to a sub-contractor's workman was based on the alleged negligence of the principal contractor. This matter was considered to be one which affected the respective insurers of the principal and sub-contractor, and any provision of this nature in a contract could only tend to complicate the issue and possibly lead to costly litigation.

The question of the proposed abolition of walking time was again considered on a letter from the operatives, refusing to accept the arrangement that the payment of lodging money or tram or railway fares on jobs over four miles from the parish church should not apply to men "started on the job." This is the main point contended for, seeing that the outside contractor in carrying out work outside the city is able to draw on local labour without paying lodging money or tram fares, whereas the local contractors would be called upon to pay lodging money or tram or railway fares to any Sheffield men who might be set on, whether or not such men had previously been in such contractors' employ. The Association are quite willing to pay lodging money or tram fares to all men sent from contractors' works to a job over four miles from the Sheffield Parish Church, but they consider it most unfair and unreasonable that they should be called upon to conform to conditions which are not enforced or sought to be enforced on the outside contractors. And so the matter now stands at a deadlock, each side having apparently reached the limit of its concession. The meeting unanimously decided that the only course was to give the prescribed notice for abolition of walking time, and this will be given in due course. The matter thus gets beyond the stage of discussion by the Trades Committee and will duly come before a meeting of the Conciliation Board, who, it is to be hoped, will find a satisfactory solution to the difficulty. The Association hold that the prolonged period of bad trade has warranted a reduction of wages, but nevertheless the operatives have not yet been asked to consider such a proposal. The abolition of walking time will put the Sheffield contractor on a level with outside competitors, and of necessity be an advantage to the operatives, who up to the present seem to take the view that it is better to allow an outsider to employ outsiders on terms to which they object, and



A WHITE CITY EXHIBITION BUILDING. ANDREW SELL, ARCHITECT.

The walls are constructed of fibro-cement slabs. The roof is covered with Buttermere green slates in diminishing courses, the chimneys, where emerging from the roof, being rough-casted. The builders are the Alnwick Foundry and Engineering Co., Alnwick and London.

thus lose the local contractor the job, and the local operative the wages. The position the operatives take up is anomalous enough, and is working to the disadvantage of both parties.

The advisability of the adoption of a uniform rate of day-work prices has occupied attention for some considerable time, and the matter was again brought forward on the report of a special committee, who after considering the prices in operation in various parts of the country, unanimously decided to recommend to the Association a uniform rate of 2d. per hour profit on skilled labour and 1½d. on unskilled labour. It was pointed out that the absence of a standard rate had led to a practice of charging only 1½d. on skilled labour, and there were even instances where a still lower rate was reported. The action of one member in sending out a circular advising a reduction of ½d. per hour on day-work prices was very strongly deprecated. After a lengthy discussion, the secretary was instructed to send out a circular to each member in order to ascertain what rate he was charging, and if he were agreeable to fix a minimum of 2d. and 1½d. profit respectively.

NORTHERN COUNTIES FEDERATION OF BUILDING TRADE EMPLOYERS.

Secretary: W. H. Hope, Solicitor.

At a meeting of the Executive Council of the Northern Counties Federation held at Sunderland on Tuesday, August 24th, Mr. J. Davison (Stockton-on-Tees) presided, and there were twelve members present.

Arising out of the minutes, reports were received upon the Darlington Association and affiliation, Auckland Union Building alterations and additions, Hexham District Council and conditions of contract, and dangers attendant upon the use of lead in the painting trade.

The question of the invitation of the National Federation to hold their summer meeting in 1911 within the Northern Counties was considered, when it was unanimously resolved to recommend to the next meeting of the Federation: "That a small Committee be appointed to go into the matter for the purpose of submitting a scheme of arrangements for entertaining the National Federation, and that the Committee consist of the presidents of the Associations on Tyneside, with power to add."

A communication received from the Teesside Association with respect to uniform working hours in that district was considered. At present the various trades work different hours, and are agreeable to fall in with the Teesside employers' suggestion that they should have uniform hours, which alteration would involve a reduction of the total hours worked, providing the labourers do not suffer any reduction in their present weekly wage, so that the readjustment therefore practically means an advance of ¼d. per hour, from 6¼d. to 6½d. This advance would only affect the Stockton and Middlesbrough Associations, the Hartlepool rate being 6½d. The matter was carefully discussed, and it was asked if the desired alteration would not be brought about by notice in a formal way, and appeal to the Conciliation Board. The Teesside secretary (Mr. Creasor) explained the position, and intimated that the feeling on Teesside was unanimously in favour of securing the rearrangement in an amicable, if informal, way. After considerable discussion, Mr. R. Johnson moved that the Teesside Association's proposals to secure uniformity of working hours be approved, all objections being withdrawn.

The financial statement was considered, and attention was drawn to the subscriptions owing from the local associations, the hope being expressed that these associations would remit without delay.

On the proposition of Mr. J. Proud, seconded by Mr. J. Pelton, accounts amounting to £10 8s. 10d. were passed for payment.

It was decided that the quarterly meeting of the Federation at Stockton be held about the third Wednesday in September.—W. H. HOPE, Post Office Chambers, 14, Norfolk Street, Sunderland.

SUNDERLAND AND DISTRICT ASSOCIATION.

Secretary: W. H. Hope, Solicitor.

A meeting of the Executive Council was held in the Board Room on Tuesday, August 17th, Mr. R. J. Huntley presiding.

A letter received from the Amalgamated Societies of Wood-cutting Machinists asking for admittance and representation, was read. After discussion, on the proposition of the president, seconded by Mr. James Taylor, it was resolved: "That the secretary reply to the communication, asking what they desire admittance to and representation upon; further, that the timber merchants be written asking if they have any agreement for working rules with the wood-cutting machinists, and after the necessary information is received, the matter will be further considered by this association."

With respect to the winter working rules, a communication was read from the joiners' society saying they are willing to give the employers' proposals a trial, which was accepted by the employers.

The secretary reported that they had to meet the bricklayers at the close of the meeting to discuss the question of the winter working rules, and it was probable that they would be also willing to accept the employers' proposals.

The amended notice had also been forwarded to the stonemasons, asking them to adopt them, so as to bring all working time into line.

At the subsequent joint meeting of the Association and the Operative Bricklayers' Society, Mr. R. J. Huntley presided.

The employers' secretary explained that the joint meeting had been called to discuss the amended proposals of the employers for the alteration of the winter working hours which were submitted to the operatives on June 22nd, 1909, and read as follows:—"From November 8th to November 27th (both days inclusive), all workmen shall commence work at 7 a.m. and cease work at 4.30 p.m., with twenty minutes for breakfast and forty minutes for dinner, except on Saturdays, when work shall cease at 12 noon, with half an hour for breakfast, making a total of 47 hours per week. From November 28th until January 24th (both inclusive), all workmen shall commence work at 7.30 a.m., and cease work at 4.30 p.m., with 20 minutes for breakfast and 40 minutes for dinner, except on Saturdays, when work shall cease at 12 noon, with half an hour for breakfast, making a total of 44 hours per week. From January 25th until February 20th (both inclusive), all workmen shall commence work at 7.30 a.m. and cease work at 5 p.m., with 20 minutes for breakfast and 40 minutes for dinner, except on Saturdays, when work shall cease at 12 noon, with half an hour for breakfast, making a total of 46½ hours per week."

The operatives said they were willing to accept the amended proposals providing the employers were willing to accept their proposal with respect to paragraph 2 of rule 5 as follows:— "A lock-up shed with fire shall be provided for the sole use of the workmen in which they can have their meals and store their tools when not in use."

The employers pointed out that they could not agree to this proposal, as, if strictly adhered to, it would entail unnecessary expense in carrying out work; and unless it is to be enforced strictly, the present form is as good as one can reasonably expect it to be; but the employers would do all in their power to see that the rule is carried out. After considerable discussion upon the matter, on the understanding that the employers would do all in their power to observe the rule, the operatives agreed to withdraw their suggestion, and agreed to the employers' proposals for the alteration to the winter working rules.

Mr. Irwin, bricklayers' secretary, said that he was of opinion that the word "sufficient" should be placed before the word accommodation in line 2 of paragraph 2 of rule 5, making the rule read as follows: "A lock-up shed shall be provided for the sufficient accommodation of the workmen's tools, and where they can have their meals," and moved its adoption, which was seconded by Mr. James Taylor, and agreed to unanimously.

With respect to rule 12, the proposal of the operatives that the present reading should be deleted and the following substituted was accepted by the employers: "These rules shall be binding on employers and employed alike, and shall only be altered after the expiry of six months' notice given between September 1st and February 28th, either party receiving notice shall be at liberty to counter notice within 14 days of the receipt of the notice."

The employers' secretary reported upon the operatives complaint against a non-local builder for violation of the working rules which had been forwarded to the secretary of the National Federation, who had made a review of the case, which was read and received.

The Sunderland and District Building Trades Association held their Annual picnic on August 19th, when 35 gentlemen, including the members, their guests, and the secretary, had an enjoyable outing. The party left Sunderland for Barnard Castle by the 9.13 a.m. train, and on arrival they were met by a motor char-a-banc, which conveyed them through Ronaldkirk, Middleton-in-Teesdale, stopping at Langdon Beck Hotel for luncheon, thence to Alston, and Hexham for dinner, after which they entrained for Sunderland, arriving at 10.16 p.m. The weather was fine, and the outing a complete success.

Notes and News.

We are informed that Messrs. William Hodge and Co., Edinburgh and Glasgow, have in the press and will shortly publish a work entitled "Construction, Equipment, and Management of a General Hospital," by Donald J. Mackintosh, M.B., M.V.O., Medical Superintendent of the Western Infirmary, Glasgow.

* * *

In pursuance of a scheme inaugurated some years ago with the object of preserving ancient royal buildings against the ravages of wind and weather, repairs are at present being carried out on certain parts of Linlithgow Palace. One apartment to which attention is being directed is the room in which Mary Queen of Scots was born.

* * *

One of the Local Government Board inspectors (Mr. H. Shelford Bidwell) has held an inquiry at Eastbourne in reference to the application of the Town Council for a loan of £15,000 for surface water drainage purposes, and £1,100 for four groynes at Langney Point. There was no opposition, and the action of the Town Council in arranging to do as much work as possible in winter time for the sake of the unemployed is greatly approved.

* * *

Before the Housing and Town Planning Bill reached the Committee stage, Mr. Henry Aldridge, secretary of the National Housing Reform Council, had written to urge the preservation of Clause 30, which, he says, "is regarded by housing reformers as in some respects the most valuable clause of the Bill, providing as it does for the making of a survey of all workmen's dwellings let below a certain rental and the keeping of a register recording the sanitary condition of each dwelling, the state of repair, sanitary equipment, including light, air, space, and ventilation, number of rooms (including bedrooms), water supply, rent, and name and address of owner, etc." It is probable, however, that the clause will be regarded as sanctioning too close an approximation to the invasion of private rights and domestic privacy.

* * *

Following the reduction of the price of gas in Paris to 20c. per cubic mètre (4s. 6d. per 1,000 cubic feet) the consumption has rapidly increased, and the New Paris Gas Company, founded in 1907, has been compelled to undertake extensive additional works, now in course of construction. The sum allocated for this purpose amounts to £1,880,000 and the area of the former works has been increased fourfold. At the present time a new retort house has been completed which is capable of furnishing 6,181,000 cubic feet of gas in 24 hours. Two new retort houses of the same capacity are under construction, and in 1910 the company will be in a position to produce 18,543,000 cubic feet daily in addition to the former output. There will then be four retort houses placed in a straight line. The old plan of working is still maintained; in each house there are six batteries of six double benches, with seven retorts n a row, open at both ends, heated by Siemens furnaces.

* * *

The text of the Development and Road Improvements Bill, which was introduced into the House of Commons last Thursday by the Chancellor of the Exchequer, has been issued. Its full title is "A Bill to promote the Economic Development of the United Kingdom and the Improvement of Roads therein." It is divided into three parts, headed respectively, "Development," "Road Improvement," and "General," and it includes a schedule providing for the compulsory acquisition of land by the Road Board or by a Highway Authority. As the text of the Bill can be obtained from Messrs. Eyre and Spottiswoode for a penny, there is no need to reproduce it here. From the building point of view the gist of it is that, if it passes, a very large sum of money can be voted for the repair and widening of the roads of the country, and this course would naturally involve a large amount of demolition and rebuilding, while the term "development" at once charms and alarms by its immense vagueness and nebulosity.

* * *

More than 16,000 masons, or about three-fourths of the total number employed in Paris, struck work on August 26th. The question at issue is the objection of the men to the system of middle-men contractors, or *tacherons*, who contract to furnish the men required for any job. The masons demand the right of treating directly with the masters. The masters are willing to suppress the *tacheron* on condition that the men accept the principle that, to a given wage must correspond a fixed amount of work, as recognised by the workmen's syndicates in all countries where labour contracts are in force. A later communication states that it is difficult to estimate the exact number of the men on strike. The most authoritative information up to date fixes the figures at about 12,000. An immense mass meeting of the strikers was held on August 27th at the Tivoli Vauxhall, in order to discuss the situation. All the speakers protested against the refusal of the masters to do away with piece work. They discussed in detail during this meeting the masters' proposals relative to a method of payment based on a regular labour contract which could be applied throughout the Department of the Seine.

* * *

We regret to record the death of Mr. W. F. Stanley, the founder of the firm of mathematical-instrument makers that bears his name. Mr. Stanley, who died on August 14th, at his residence in South Norwood, had attained to the age of 81. He was born at Buntingford, Herts, where he gained his early mechanical training in the workshops of his father, who was a mechanical engineer. Mr. W. F. Stanley started in business as a worker in metal and ivory in 1854, and in 1856 he invented the first open stereoscope; but it was in the invention and improvement of drawing and surveying instruments that he gained his high reputation; his first patent in this kind—a bolt to hold firmly the needle of a pair of compasses—being taken out in 1860. He was the author of several scientific treatises, and was an enthusiast for technical education and the handicrafts, founding, in furtherance of his ideals, some trade schools at South Norwood, where, also, he was a generous benefactor in other interests.

Trade and Craft.

Boom in Asbestos Slate.

It is evident that intelligent manufacturers can still hold their own in this country, despite foreign competition. The British Uralite Company (1908), Ltd., report that their current output is phenomenal, as instanced by 200,000 tiles having been just shipped to the Argentine against one order, and 70,000ft. to a West Indian port. This is quite independent of home consumption. They have so arranged their plant, which is supplied by a large engineering firm near London, as to produce 1,000 tiles per hour, and this is hardly deemed sufficient for the orders in hand.

A New Anthracite Heating Stove.

The "Alpha" stove, No. 1, which has just been introduced by the Carron Company, of Carron, Stirlingshire, is specially constructed for burning anthracite coal or coke. The fire chamber is brick-lined, and fitted with movable bottom grates operated by outside handles, thus removing all ash or dust into the ashpan at the foot of stove. All joints are airtight, insuring perfect combustion, which is regulated by the ventilator in the ashpan front. The fire-door is fitted with mica front and nickel-plated handle. The stove is supplied in various finishes, as black-leaded, dull Berlin blacked, finished in armour bright, rough, or best, or in majolica enamel of various colours,, and the prices are graded accordingly.

Insurance.

Free £500 Accident Insurance Coupons have this week been sent to the following:

W. S. P. (Sheffield), F. K. T. (Handsworth), J. T. J. (Moffatt), P. M. B. (London, W.), F. B. (Nottingham), T. L. (Nantwich), J. W. (Highbury), O. H. W. H. (Hessle), E. C. O. (Torquay), G. A. H. (Llandudno), F. D. C. (Beckenham), G. S. H. (Bruton), S. A. (Oldham), J. G. (Dublin), W. E. C. (Ewell), H. D. (Leicester), W. H. A. (London, W.C.), E. L. (Oldham), B. A. H. (Kington), H. E. B. (Banbury), H. H. (Stamford), C. H. D. (Alton), H. G. C. (Chatham), A. C. (Brighton), C. A. C. (Chatham), J. A. (Greenock), F. J. M. (Haslemere), E. H. (Petersfield), L. J. R. C. (Parkstone), W. J. (Manchester), W. G. W. (Llanfairfechan), A. L. C. (Minehead), H. F. (Chelsea).

Homan's Fire-Resisting Floors
Have been executed in over 3,000 Buildings, and are the most efficient and economical.
Constructional Steelwork of all kinds,
Cast Iron Columns,
Concrete Staircases,
Granitic Work,
Asphalte,
on Roofs, etc.

HOMAN'S HOLLOW-BRICK FLOOR.

Advantages of this Construction:—
No centering required,
Rapidity of Construction.
Is practically sound proof,
Qualities:—
Light in weight,
No discoloration of ceilings,
No hacking of ceilings, the grooved bricks giving an excellent key for plaster,
Moderate in price.
HOMAN & RODGERS, ENGINEERS.
Offices:—17 GRACECHURCH STREET, E.C. Works:—NINE ELMS LANE, S.W., & WARE, HERTS.
Telegraphic Address—"Homan Rodger, London." Telephone No. 1026 Avenue.

TO BE PUBLISHED IN SEPTEMBER.

"SPECIFICATION,"

No. 12, 1909-10.

Special Points about the New Edition.

1. It has been very drastically revised and brought up-to-date in conformity with the opinions and suggestions of many well-known Architects and other professional men.
2. A general Index of Special Articles on Planning and Equipment which have appeared in previous issues is included.
3. The information has been rigidly condensed in order to reduce the bulk of the volume, and to make it easier for reference.

The Scope of "Specification."

"SPECIFICATION" provides all the information that professional men require when preparing drawings, writing specifications, or compiling bills of quantities. Previous to its publication such information could only be obtained (and then inadequately) by the consultation of a large number of books.

For Convenience in reference "Specification" is arranged under the usual trade headings of a complete Specification of Works. The book is fully indexed. Model specification clauses are given.

All the sections are contributed by Specialists in the particular branches of the subject of which they treat.

In view of the fact that architects, surveyors, and municipal engineers meet on common ground, and have to deal with subjects very closely allied, information upon municipal engineering subjects is included in "Specification." Architects and surveyors often have to undertake the same work as the municipal engineer, namely, sewerage and sewage disposal systems, road making and water supply, &c. The Municipal Engineer has always been greatly concerned with building construction, and is becoming still more closely connected therewith.

List of Sections.

The information in each section is contributed by a Specialist.

Division I.—Building Construction.

1. General Conditions.
2. Excavator.
3. Drainlayer.
4. Concretor.
5. Bricklayer.
6. Mason.
7. Terra Cotta & Faience Worker.
8. Structural Engineer.
9. Fireproof Constructor.
10. Pavior.
11. Carpenter.
12. Joiner.
13. Ironmonger.
14. Roofer.
15. Ventilating Engineer.
16. Heating Engineer.
17. Founder.
18. Smith.
19. Plumber.
20. Bellhanger.
21. Mechanical Engineer.
22. Electrical Engineer.
23. Marble Mason and Mosaic Worker.
24. Plasterer.
25. Glazier.
26. Painter and Decorator.
27. Paper Hanger.
28. Horticultural and Landscape Architecture.
29. Blind Maker.
30. Furnisher.
31. Art Metal Worker.

Division II.—Municipal Engineering.

32. Roads.
33. Sewerage.
34. Water Supply.

The Crux of Competitions. With reference to our few and casual remarks, in last week's issue, on the perennial and increasingly important subject of competitions, a correspondent expresses surprise that we did not then seize the opportunity to protest against the hardship inflicted on the rule-abiding competitors when an assessor premiates designs whose authors have deliberately disregarded some of the controlling conditions. "For example," writes our correspondent, "the architect who exceeds the stipulated cost by £5,000, or even by a much less sum, assumes a winning advantage, providing the assessor and the client will wink at it, and such audacity on the one hand, and such complacency on the other, are manifestly unfair to those conscientious competitors who scrupulously confine themselves within the limits." Certainly we had by no means overlooked this cardinal point. But it was so self-evident, and had been dealt with so recently in these pages, that it seemed to be in no urgent need of further emphasis. Moreover, it seems to us to be a point of which the importance can be easily exaggerated. Whilst admitting, as we needs must, that competitors should neither be penalised for observing the rules nor rewarded for breaking them, we would nevertheless repeat our plea for some degree of sympathy with the hard case of the embarrassed assessor, on finding himself confronted with conditions that demand interpretation rather than obedience, and really deserve to be either broken or burnt. Conceive his difficulty. He has to decide between conditioned and absolute merit, between designs that are relatively inferior because they are strictly governed by conditions that in some particulars are patently absurd, and other designs that are superior because their authors have temerariously disregarded those particulars. It does not seem so very wonderful that he occasionally—perhaps more often than not—follows the more audacious course, and selects what seems to him to be the best design, independently of literal obedience to details that, architecturally speaking, are better disregarded. That seems to us to be the crux of the matter. As to the morality of such decisions we prefer, for the moment, to say no more than this: that it must not be forgotten that the assessor may possibly feel it to be as much his duty to be faithful to his art and loyal to his employers as it is to insist that all the competitors should toe the line. The mischief arises when the conditions are so faultily drafted as to compel an unnatural antagonism between these interests.

Dolly Statuary. Mr. Clement Shorter, travelling in France, has noted the much greater prevalence of statues in that country as compared with this. Seeing that the French know so much better how to compose statuary, the disparity in numbers is not altogether to be regretted. Seeing that so much, even most, of our outdoor sculpture is so sadly out of harmony with its environment, and that it suffers so severely from the ravages of a soot-and-sulphur laden atmosphere and of a devastating climate, architects are more than ever inclining to the belief that it should be used very sparingly if at all. In particular, they have grown tired of the colossal bronze or stone doll elevated on an inartistic pedestal, and braving, bareheaded as often as not, the vagaries of the English weather. Your monumental group, nobly conceived, and as nobly situated, may perhaps add grace and dignity to a park or square; but the one-man statue (how few are the women commemorated!) should be hospitably entertained indoors out of the wet, and only that by invitation of a responsible architect; who, however, if he have the root of the matter in him, will probably share in our own personal objection to seeing any fine building converted into a sort of dolls'-house. Sculpture should never have been divorced from architecture; and we cannot share Mr. Shorter's regret that the evidences of this upstart independence are fewer in this country than in France.

Patriotism in Art. Our national diffidence in matters of taste is commented upon by Mr. Walter Crane, incidentally or allusively, in a letter which he has addressed to a daily newspaper with the main object of removing certain misconceptions with regard to some work of his and with respect to the aims and influence of the Arts and Crafts Exhibition Society. He finds it necessary to state that he is not "answerable" for the Arab Hall of the late Lord Leighton. The building is planned on the lines of the old Palace of La Ziza, at Palermo. Mr. George Aitcheson was the architect, and Mr. Crane claims only the design of the mosaic frieze. "As to the question of parental responsibility for that *enfant terrible 'l'Art Nouveau,'* " Mr. Crane writes, "when the inner history of the Arts and Crafts movement comes to be written, I think it will be found to be of Scottish and Continental descent. The influence of the Arts and Crafts Exhibition Society as a body may be said to have been entirely counter to it, as one of our main principles is the fitness of design to material." The innuendo in the last sentence is surely a master-stroke of quiet satire. Not less incisive is the observation to which we set out with the express object of quoting. "With regard to the existence of a distinctive English style in decorative art, it is curious that, while the English style is quite frankly recognised on the Continent, where it is eagerly studied and welcomed, it appears to be ignored or to be invisible to the native eye, our people preferring in their turn foreign importations. There does not appear to exist what one might term patriotism in decorative design, except, indeed, in Sweden and in Hungary, where there is national pride in the forms of the traditional peasant arts and handicrafts of those countries, which are carefully fostered and encouraged as of national importance." We should have thought that Italy might have made up a trinity for Mr. Crane's commendation; but, at any rate, it is only too true that English self-effacement in matters of art almost amounts to a disease. It may even be doubted whether the peculiar charms of our English domestic architecture were realised at home until enthusiastic foreigners generously pointed them out.

York Minster Endangered. A line that appeared on the placards of most English newspapers on the first day of the present month filled the lover of architecture with genuine alarm. It was "Fire at York Minster." The foreboding gained intensity from the knowledge that some buildings seem to be specially marked out by some inscrutable fate to suffer from fire, and that apparently York Minster is one of them. Edwin's Minster at York was burnt down, it is supposed, in 741. Albert rebuilt it in 767-780, and his building was destroyed by fire in 1069. The nave, transepts, and probably the choir, were re-edified in 1080, and building of various portions went on intermittently until late in the fifteenth century, when the north-west bell-tower was erected. The choir was injured by fire in 1829, the nave in

1840. It was in the north transept that the fire of August 31st occurred, and as this part of the Minster appears to have been built between 1241 and 1260, it was extremely gratifying to learn that the outbreak was promptly suppressed, the fire hydrants installed in the Minster having been used with excellent effect; otherwise we might have had to mourn an irreparable and a truly lamentable loss. The transepts, each of them four bays long, show a length from north to south of 223ft., with a width of 93ft., the height to the summit of the roof being 99ft., and to the top of the lantern 180ft. "Taken in conjunction with the lantern, they produce an effect to be found in no other Gothic church in the world. In England there are none so wide and so lofty. In France there are interiors even loftier, but in France the transepts are seldom a prominent feature of the design. Often they do not project beyond the outer wall of the aisles of the nave, and oftener still there is no central tower large enough to allow of a lantern at all." In the eastern aisle of the north transept is the very fine tomb, in the fullest beauty of the Decorated style, of Archbishop Greenfield, who died in 1315, the statue of the archbishop being, however, a modern addition. It was behind this tomb that, in 1829, the lunatic Martin hid himself before setting fire to the Minster. In the present instance the fire originated in the lower roof, which was under repair. The roof of the transept is, the more is the pity, covered with zinc, which was substituted for old stone tiles that were found to be too heavy.

Form and Colour. The architect or the decorator who is amative of his art, and who of course keeps a commonplace-book, in which to enter any felicities concerning it, may be glad of this item concerning two views of colour. It is derived from a review, in the "Morning Post," of a new book on Rubens: "The Florentines, using colour to define form, thought of it as a property of form. Florentine colour is an adjective. It is used to qualify a noun, and its own duty and merit consist before all in its qualifying its noun correctly. The Florentines' interest in art was an intellectural interest, and, having at all times something significant and fine to say in their compositions, their tendency, like the Attic tendency, was towards purity of outline and an exact articulation, conditions to which colour was subject. But in Venice the case was utterly different. To the Venetians colour itself was a noun. They thought not of a blue this, a yellow that, and a red the other, but of blue, of yellow, of red. Their compositions presented themselves to their imagination not as a collection of definite shapes of intellectural significance, but as melting depths of colour of emotional significance." The Grammar of Ornament, it would seem, may advantageously borrow its terminology from the grammar of language. But how do you change your point of view so as to regard colour as adjectival or substantival? The answer is that "a great scheme of chiaroscuro is able to make up forms as it pleases, to separate, combine, and unite them in masses, and for purposes of its own. Following this larger distribution, colour finds itself released from its narrow servitude to form, and able to participate in great effects of glowing light or darkening shadow." This seems to be a point that decorators should study with care, as the distinction drawn with such subtlety would, when thoroughly understood, help them to a much clearer view of the functions of colour, and will prove as useful in indicating the limitations as in suggesting the possibilities of their resources. Where the object is not pictorial, the decorator will doubtless be well advised to keep to the Florentine or "adjectival" view of colour; the form being as a rule supplied to him as a concrete entity. He has not to make it, but to colour it. The jotting, at all events, is thought-provoking, even though it should turn out to be of no great practical value.

The Tardy Revival. The business outlook is improving very gradually, and is attended with all the hopes and fears of a slow convalescence; the haunting dread of a relapse still subduing voice and movement. In this matter also a cheerful atmosphere is highly beneficial to the patient, and helps materially towards recovery. Signs of improvement are not lacking. The London bankers report brisker business. The woollen and worsted manufactures show distinct expansion, so that the millowners should soon be in a position at the least to settle their little accounts with architects and builders, even while the improvement is not yet sufficient to warrant any great amount of building extension. The iron and steel industry, both in this country and in America has taken a turn for the better; but this improvement, while heartily welcome as a symptom of reviving trade, is likely to have a directly adverse effect in sending up the prices of materials. This is not altogether a disadvantage. It will have a steadying influence on any tendency to travel too fast or too far in advance of the boom that seems to be coming along; and it will bring prices to the healthy normal level below which they may not sink without creating all sorts of fortuitous and fallacious conditions; as, for instance, when a merchant or manufacturer, grown desperate over his excessive stock, parts with it below cost to a builder or contractor who is by this means enabled to underbid his neighbour, and incidentally to create further depression in the trade. Of course the symptoms of revival are seasonable at any time. It is nevertheless regrettable that the improvement is coming along so slowly that it is not likely to have any very marked effect on this year's building accounts, nor to mitigate to any great extent the gloom of the coming winter; but there seems to be every reason to hope that next spring will see a renewal of that briskness in building of which we have almost forgotten the joyous sensation.

Too Many Houses. A Local Government Board enquiry of rather unusual character has been held at Manchester. It related to the application of the Manchester City Council for release from the obligation to build dwellings to take the place of some that have had to be demolished. The City is unhappily by no means exceptional in having ready to hand housing accommodation enough and to spare. It held a very prominent position in the return of places issued a week or two ago by Mr. John Burns—"returned empties," someone has called them—in which empty houses throw an excessive burden on the community and bring building enterprise to a standstill. Manchester, like most other large towns, is feeling the effects of comparatively recent developments of the transit service. People naturally prefer to get as far away as they can from the smoke and bustle; and this desire is stimulated by the love of novelty. Houses of old type are on this account willingly discarded for what is new in arrangement and in appearance as well as in substance The habit of "flitting," formerly peculiar to the far North of these Islands, seems to be spreading rapidly as the means of gratifying it increase; and the nests that are quitted in the process of flitting, whether or not the flitters be winged and feathered, commonly remain forsaken. In Manchester, as in London, complaint is made that the newness of the suburban houses seems to be their chief attraction, for they have no beauty that men should desire them. In particular, they show the dreary monotony of elevation that has made Suburbia a by-word, and takes the sting out of the chief reproach that has been levelled at Mr. Edison's "poured" houses, which, being all cast from the same mould, would all look exactly alike. Indeed, Mr. Edison seems to be justified of his boast that with half-a-dozen moulds of different patterns he can give more variety of elevation than is usually perceptible in our long lines of deadly monotonous suburban streets; and we are quite without his excuse of cast-iron necessity. A repeat-pattern of essentially pretty elevations, extending through miles of streets, is in the net effect rather more appalling than a town-full of ugly houses that at least show diversity in their hideousness. Uniformity is a foe to picturesqueness, and a foil to town-planning.

THE PARIS MASONS' STRIKE.

At a mass meeting of Paris masons now on strike, which was held at the Tivoli-Vauxhall on September 1st, the delegates of the Masons' Union were empowered to treat directly with the representatives of the Contractors' Union. Some rioting took place outside the building as a result of the efforts of the police, who were assisted by the mounted municipal guard, to obtain possession of a red flag which bore the inscription "Respect for the Law of 1848: Death to the Employers." There was a sharp scuffle, but no one was seriously hurt.

The agreement drawn up by the Paris masons for signature by the employers demanded the abolition of sub-contractors, master-men, and piecework. The men also stipulated for a working day of nine hours all the year round, subject to reduction by mutual consent in times of slackness. Extra time may be worked, however, in cases of urgency, when an increase of twenty-five per cent. on the normal wages will be exacted. Night work is to be charged double. The wages per hour asked are as follows:—Macon, 90c.; garcon macon, 70c; macon limousinant, 85c.; garcon limousinant, 65c.; poseur, 1fr.; pinceur, 90c.; bardeur, 80c.; night watchmen, 4 francs the night. These rates are to apply all the year round, and the men are to be paid on the job; if they are required to make a journey to the office, the employer is to pay for the time occupied in making the journey. Fares are to be charged against employers where jobs are at a distance—as, for instance, outside the fortifications—and the time taken to make the journey is to be credited to the workmen; and, where the mason is compelled to sleep away from his home, the expenses of his lodgings are to be defrayed by the employer, who is to pay on this account a minimum of three francs a day. Payment is also demanded for any loss of time for which the workman is not himself responsible. Lock-up sheds for the safeguarding of clothes and tools are also demanded.

Architects of the Day.-IV.

Mr. George B. Post, of New York.

George Browne Post was born December 15th, 1837, educated as an engineer in the University of the City of New York, and graduated in 1858. It was in that year that the late Richard Morris Hunt first opened his *atelier* for students, and Post entered this school at the same time with the late Charles D. Gambrill, who was first his partner, and afterwards the partner of Henry Hobson Richardson. In the year 1861 the Anti-Slavery War took Mr. Post away from his practice, and kept him for some years in the service of his country. This dissolved the firm of Gambrill and Post. The war over, Mr. Post returned to the practice of architecture, and began to come into prominence as the architect of large and important buildings about the year 1875; and during the years that have elapsed since then, his business has been one of the largest in the United States.

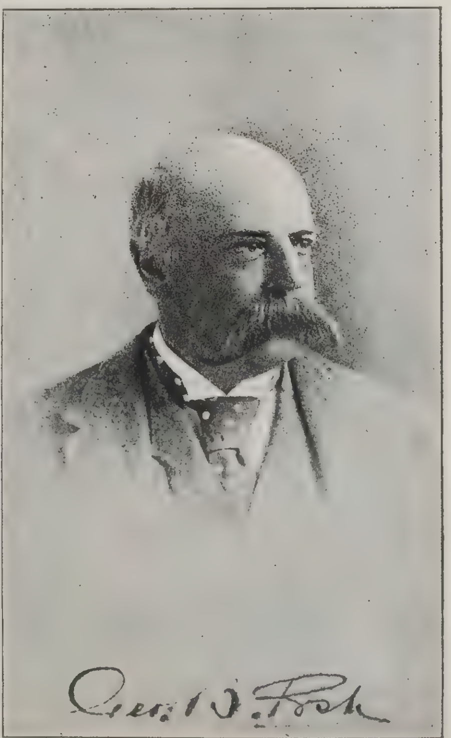
This business is, moreover, distinguished by the importance, from a social and commercial point of view, and by the high cost of many of the buildings, as well as their extremely thorough and workmanlike construction. Many American cities have, among their most important public and mercantile buildings, the structures erected from Post's designs, and several of the most sumptuous and splendid residences in America are also of his work. These buildings are appropriate and enduring, useful and worthy, and, as instanced by his late works, are not without conspicuous artistic merit. Of his earlier work the late Russell Sturgis wrote: "That charm of conventional proportion which, in our modern practice, can only be got by the deliberate sacrifice of convenience and logic to the massing of lines of a facade, is not especially a characteristic of his compositions. On the other hand, these buildings are admitted by all to be among the best built, best planned, most useful and most truly economical of our modern structures. It is, moreover, generally admitted that this architect, more than most men in very large practice, designs his own work. Of course, the mysteries of a working office are impenetrable. No one really knows which member of the firm, or which subordinate of the many in an office of seventy or eighty employees, is really responsible for the merit or demerit of a design. We call a building the design of Smith or Brown, because Smith or Brown is the responsible man; it is he who has received the commission and who draws the percentage; but who deserves the credit or discredit of the plan, the general design, or the details, is absolutely unknown to the outside world. And yet it is not to be doubted that the architect whose work we are now considering does far more of his own original planning and designing—arranges his own studies far more thoroughly and in person—than is at all the rule. It is not many months since Mr. Post said, himself, in the course of discussion at the Architectural League, that the limit of business in his office was that of his own capacity to originate the designs—to make primary studies—and it is probable that no one of those present was inclined to dispute this saying, rash as it seems, and almost incredible, if measured by the well-known practice of many architects in a large way of business."

Since the above paragraph was written Mr. Post has taken into partnership with him his two sons, Mr. William S. Post and Mr. James Otis Post, whose more modern and more thoroughly artistic training has doubtless assisted greatly in the continued improvement which has constantly been observed in Mr. Post's work since the earliest examples began to attract the attention of the American architectural profession.

To use the words "continued improvement" might possibly suggest the idea of "damning by faint praise," and if we were to consider the earliest of Mr. George Post's work as representing in the least his present understanding of architecture, or that his work to-day were merely "improvement" over that of the period of time between the closing of the war and the opening of the Columbian Exposition, the idea might not improperly be suggested. Such, however, is far from being the fact. In few recorded instances has the existence of latent talent been so clearly proved as in Mr. Post, by his works since the days when, through association with a number of brilliant artists, his own artistic instincts were awakened.

One may classify Mr. Post's work into four principal divisions as to time and style: first, his "engineering" period, when he produced the very large, important, and altogether hideous Pulitzer building, Park Row, New York, and one or two others equally unlovely; secondly, his experimental period, when he became more interested in the beautiful side of his work and presented the Produce Exchange Building, at Bowling Green, the old "Times" building in Park Row, the Union Trust Building in Broadway, New York, the first Prudential Building at Newark, N.J., and the building of the Erie County Savings Bank at Buffalo, N.Y.; thirdly, his period of development, when he produced the Cornelius Vanderbilt town house—probably to-day the largest in New York, the Liberal Arts Building at the Columbian Exposition, the Bank of Pittsburgh, and the Park Building at Pittsburgh, Pa., and the Huntington residence in Fifth Avenue, New York; and fourthly, his period of achievement, which may be said to have begun with the strong design which won the competition for the building for the Department of Justice at Washington, D.C., about ten years ago.

Of the earliest of these stages of his work all that should be said in fairness is, that it was much better in construction, and a little better in design, than what was being done by other so-called architects at the time—a time when architecture had almost ceased to exist in all countries boasting "Western civilisation." It was not *architecture* in the sense in which we use the word to-day; it was only good building, which grew simpler, and consequently better as years went on. In the Produce Exchange there is a hall of great dimensions, which is wonderfully effective, due to good proportions and simplicity of scheme. It impresses one immediately as the work of an artist untaught beyond the first rudiments of his art, but not without great native ability. This Produce Exchange Building and all of the vigorous designs mentioned as belonging to his experimental period show the influence of the work of Richardson, but more than this, they reflect truly the life and spirit of the times.



Geo. B. Post

It may be said that the architects of the Columbian Exposition educated themselves at that exposition, since it is a fact that several of those who took part in the work upon that famous design had never done anything else comparable with what they did there. Mr. Post was one of the members of the Board of Architects, and architect of the Palace of the Liberal Arts—from a general point of view, perhaps the finest exposition building that has ever been built, and which was the largest of the Chicago exposition buildings.

For several years following the exposition Mr. Post's work was almost exclusively the commercial class—the gigantic office building being his portion—and with this class of work he kept busy a large number of draughtsmen. But enthusiasm in the artistic side of his profession had been much developed by his experience upon the work at Chicago. Association with such artists as Hunt, McKim, Burnham, Atwood, and Saint Gaudens, had aroused his deep interest in the arts, and especially in monumental architecture, of which his first remarkable study was the successful competitive design for the Department of Justice at Washington—above mentioned. This Department of Justice design is a scholarly study in architecture, at once Classic, modern, and distinctively American.

An entirely different style and feeling is evident in the interesting group of buildings built soon afterwards for the College of the City of New York. This is built on a most admirable site, bounded on the east and north by the curving line of St. Nicholas Terrace, from which the hill goes steeply down to Harlem Flats. To the west and south the ground is level, or even rises a little from the College site, and the entrance front, with its triple gateway, is seen by persons approaching it along what is practically a common city street without much rise or fall. On the other hand, the perspective view with the tower (p. 182) is practically what is seen by the person approaching the building by climbing the steep hillside which will of necessity always be used as a park, the view which is seen by anyone a mile away on what used to be called Harlem Flats. If, in other words, one were to stand on top of a house at 150th Street and Sixth Avenue, the point which we take to be practically coincident with the edge of the Harlem River at that point, he would see the college in this way, or nearly in this way. The Tudor Gothic or "Collegiate Gothic" style of this work suited itself well to Mr. Post's idiosyncrasies as a designer. It appears that the persons charged with the responsibility of selecting a design after what proved to be a very thorough and fair competition, found themselves led to the conviction that this style, associated with memories of Oxford and Cambridge, was what they desired to see used for the new building. A fresher and less "decadent" one would have pleased many of us much better, but it has been interesting to see what this essentially picturesque designer has made of this rather conventional style. The plan is worked out with closest regard to common-sense and the requirements of the situation, and the exterior design has been developed naturally from that well-studied plan.

Since its completion much has been published in regard to this group of fine buildings, and much harsh criticism has been hurled against it, particularly as regards the colour scheme. Due allowance has not been made by the critics for the weathering properties of the materials used, and the ultimate effect when partly covered with vines and relieved by the trees and shrubbery now being added.

The strong character of the design and vigour of its scale are shown by the illustrations of the main hall from the garden side (p. 184), and the detail of the entrance to the Mechanical Arts Building (p. 190).

In his New York Stock Exchange (p. 188), built in 1901, Mr. Post returned to the Classic style, and scored a great architectural success. It is located between Broad Street and New Street, with a side entrance on Wall Street, on a site approximately one hundred and fifty by one hundred and twenty feet. The front to Broad Street, being 140ft., and that to New Street being 153ft., and the entrance on Wall Street 15ft. (page 188). All of the facades, and also the interior, are built of white marble. The Exchange Hall is 86ft. high. The floors above this room are carried on four double girders, 15ft. deep, which span a clear space of 111ft. The twin columns supporting the ends of these girders are 100ft. in height. In design and construction the building was peculiar and original. The requirements demanded that the great hall in the Exchange occupying the principal floor should be as large as possible, and that it should be provided with the maximum amount of diffused light. This result was accomplished by making the colonnades at the ends of the hall on its two street fronts themselves form the end design of the hall, by placing behind them continuous screens of glass. This design is believed to have been entirely original, and it has been extensively copied.

The system of heating and ventilating in the building was also a novelty, and has been entirely successful. The building is heated by direct radiation and ventilated throughout by air of the same temperature, which is forced into the rooms under pressure through carefully placed registers, and removed by a system of exhaust ducts, the position of which has also been carefully selected. From the Exchange Hall the air is removed from the outside walls at a point slightly above the level of the heads of the brokers, and through the tops of trading posts, which are fixed pieces of furniture spaced at regular intervals over the floor. The result has been that during an exceptionally cold snap, when the thermometer fell to 16 degrees below zero, that a variation of but 1½ degrees of temperature could be found in any part of the building. In summer, when the heat is excessive, the incoming air is passed over the coils of a refrigerator apparatus through which zero brine is pumped, and the air is not only cooled, but the moisture which it contains is partially frozen out of it, and the result of this system, which was used for the first time in this building, has been to reduce the temperature by 7 degrees, which was found practically the extent it could be reduced without discomfort to the brokers, and to reduce the humidity, which is far more important than a reduction of temperature 70 degrees.

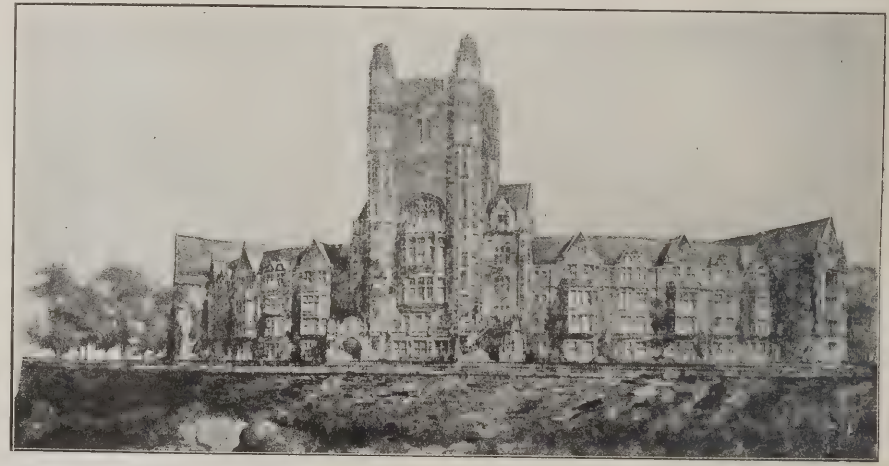
The construction of the building formed a very puzzling engineering problem. The lot was partially occupied by the old Stock Exchange, which contained in its basement a safe deposit vault of very large dimensions, which was filled with millions of dollars of treasure and securities. This vault was constructed on a crust above the quick-sand at a level of about four or five feet below the principal street, and it was essential that the new building should be constructed without disturbing this vault until another could be constructed to which the treasure and securities could be moved. It was evident that in order to provide spaces for the necessary mechanical plant for the building, the cellar would have to be constructed to contain it below the level of the old safe deposit vault, and consequently below the level of the water in the lot. It was evident that if a water proofed cellar were constructed (no matter of what material) sufficiently rigid to retain its form, it would have a flotation. Inasmuch as a great portion of the space above the basement floor was a void, the flotation would be many times the load which could be imposed on the cellar in order to hold it in position. The problem was solved by sinking pneumatic caissons of wood to bed rock touching each other as nearly as possible and in the form of parallelograms. Each caisson was filled with a strong concrete with a semi-circular void several feet in diameter at each end where the caissons nearly touched each other; through this void the caissons were drawn together with bolts, after which the wooden forms between the voids were removed and the joints caulked. A round concrete key was filled into the voids, making a continuous dam around the entire lot to bed rock, extending to a depth of about 50ft. below the curb. Inasmuch as this dam was necessary to the construction of the building, and inasmuch as the ground was extremely valuable, it was decided to excavate the entire lot and utilize the space to a bed rock level. When the entire work was completed the leakage was taken up by a one-inch pipe.

The columns supporting the floors to the level of the great hall were spaced to avoid the old safe deposit vault, and were carried to bed rock through cylindrical pneumatic caissons before any excavations were done. The weight of the old safe deposit vault was transferred to girders between these columns before the remainder of the lot was excavated, and the work was so carefully executed that the old vault was in constant use by the depositors until the new vault was constructed and the securities removed to it.

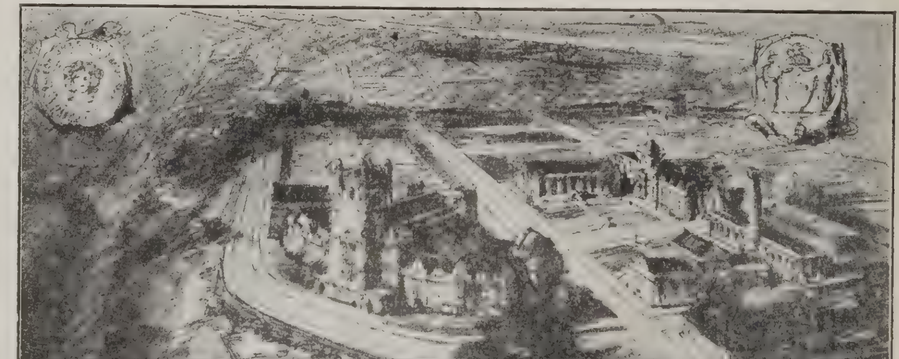
As soon as the dam which formed the foundations of the exterior walls and the interior columns were set, the erection of the building was pushed forward rapidly, and at the same time the excavation of the lot was commenced, which led to the very singular result that the excavation of the lot was not entirely completed until the building was under roof.

The design for the Mutual Benefit Life Insurance Co. Building was selected in competition.

This building, recently erected, is on Broad Street, Newark, and is on a plot of land 191ft. by 99ft. The problem was to design a building indicative of the strength and greatness of an important insurance company. The principle of the design of the New York Stock Exchange, i.e., large free standing columns in front of a glass screen, was followed. The Corinthian order was used, the columns being four storeys high, supported on a base and crowned by an attic. The dead storey behind the main entablature is completely used for filing and storage purposes. The exterior of the building is of white marble, with window screens of copper treated to imitate bronze. The south side of the first floor is occupied by the National Newark Banking Co., and the north side by bankers' offices. The walls of the main corridor are lined with white Vermont marble. The interior of the building is of simple design, appropriate for use as offices, with the exception of the Board Room, which is more ornate and beautifully decorated. The main office of the Cleveland Trust Company is situated on Euclid Avenue and East Ninth Street, Cleveland, Ohio, and has a frontage of 140ft. on Euclid Avenue, and 123ft. on East Ninth Street. The main feature is the Euclid Avenue facade, which has a colonnade of eight fluted columns of the Corinthian order, carrying a pediment with very beautiful sculpture, by Karl Bitter. The building, monumental in character, is built of white granite, and used exclusively for banking purposes. The main entrance



MAIN BUILDING, COLLEGE OF THE CITY OF NEW YORK. GEORGE B. POST, ARCHITECT.
The Tudor Gothic or "Collegiate Gothic" style of this work, which suited itself well to the idiosyncrasies of the designer, commended itself to those who chose it by its associated memories of Oxford and Cambridge.



BIRD'S EYE VIEW, COLLEGE OF THE CITY OF NEW YORK.

leads to a marble lobby, with a staircase arranged at one end and elevators at the other. Directly opposite the entrance are openings to the main banking room, the women's department and the junior officers' quarters, respectively. An entrance also leads into the main banking room from the East Ninth Street facade. The entire first floor is given up to the great rotunda-like banking-room and its dependencies. This room is 61ft. in diameter, and rises to a clear height of 85ft., and has a leaded glass dome. It is finished in marble and bronze, which produces a harmonious and rich effect.

Another fine classical design for a bank is that of the Howard Savings Institution at Newark, N.J. (p. 187).

The design for the group of buildings for the George Washington University—which was planned as part of the great monumental plan of the Capitol City of the United States—was selected in competition in 1905. It is still another fine classical composition of Messrs. Post and Sons (p. 191). The programme was an unusual one, being composed of two parts—one being for the University Buildings, and the other for a Memorial Building to be erected by the George Washington Memorial Association as a memorial to George Washington. Messrs. Post's plan for George Washington University constituted one of the ablest studies which have been made for the details of the city plan of Washington.

Another magnificent piece of city planning—and of a kind too infrequently attempted by architects—is his plan for the suggested improvements of the harbour of Newport, Rhode Island (p. 185).

The capitol building for the State of Wisconsin now in course of construction is a public monument of first importance, and as a work of American architecture will rank the greatest among the many works thus far produced, with which the names of Post will be for ever associated. The site upon which this Capitol is located is one of singular beauty. A square park, situated between two lakes and on the crest of an elevation of land, from the centre of which all of the principal avenues of the city of Madison radiate, both on the direct and diagonal lines, together with the original instructions of the Commission to the competing architects that the building should be cruciform in plan, led to the creation of a design which is radically different from any other existing State Capitol. It possesses singular points of interest both practically and artistically; practically in the fact that the various departments of the government which occupy the building are brought into the closest possible communication with each other, and at the same time are in separate wings of the building, and artistically in the fact that the great central architectural feature of the building, the dome, which rises to the height of about 200ft. above the four wings to the top of the crowning figure representing "Wisconsin," will be approached directly through monumental entrance pavilions constructed on the re-entering angles of the building; and added to this the fact that the whole building to the top of the cupola is of white Vermont granite. On the line of the direct avenues dignified grand staircases lead up to the first floor level of the entrance pavilions. These serve, too, as shelters for the carriage entrances to the ground floor of the building, which may also be entered on the ground floor under the porticos at the end of each wing. The four wings placed on the diagonal lines of the Park on the extension of the four avenues, terminate in dignified porticos composed of six Corinthian columns supporting pediments, in the tympanums of which are groups of statuary by Karl Bitter, that of the west wing representing "The Unveiling of the Resources of the State," and that of the east wing representing "Liberty Supported by Law." The proportion of the building from all directions is enhanced by groups of statuary at the base of the dome overlooking the corner pavilions, which not only add materially to the interest of the design, but to the pyramidal effect of the entire composition. Advantage has been taken of the opportunity afforded to make a thoroughly unique design for the interior, and by the disposition of the grand staircases unobstructed vistas about 200ft. long have been left from the principal rooms in each wing. On the ground floor uninterrupted vistas extend the whole length of the building, more than 400ft. The interior diameter of the dome is approximately 75ft., and its height from the ground floor level to the eye about 200ft. Galleries encircle the rotunda. Those on the second floor level are supported by Waupaca red granite piers, which in turn are supported on the ground floor by Wisconsin green granite piers. The piers which flank the grand staircases are similar, and are erected with each wing. The gallery railings are similar to those of the staircase and stair galleries of each wing. The wall lining of the central portion of the building and the staircase halls of each wing is of beautiful soft-toned Kasota stone. This is up to the main cornice line, above which it will be plaster. The same stone is also used for the wall lining in the main corridors of the first and second floors of the wings, the wall base being of Hauteville marble. On the ground floor corridor stone is used, the skirting and columns being of marble. The staircase rails and the balusters are of dark red Tennessee. The treads and risers are of Meadow Grey Tennessee. The main pilasters of the staircase halls are of Pike River red granite, and the columns flanking the entrance doors to the lobbies of the principal departments at the end of the staircase halls are of red granite. In the interior design Wisconsin stones, or stones from the immediate neighbourhood of the State, have been used wherever practicable, and the architectural effect has been gained rather by elegance of proportion and careful selection of colour than by great elaboration of ornamentation or detail. Where enrichments are used, they are concentrated at the points where they will give the greatest effect, and the best talent has been employed to prepare the necessary sculptural models. In designing the three great rooms of the Capitol—the Assembly Chamber and the rooms of the Supreme Court—the architects have avoided the use, in spite of their architectural beauty, of heavy vaulted ceilings or domical forms, in order to secure as far as possible a good acoustic quality, bearing in mind the fact that the speaker will have to address the audience from any part of each one of the rooms. The form of the Assembly Chamber (A) in the west wing is approximately 73ft. by 68ft. by 41ft. high, lighted through a large circular ceiling light of low-toned leaded glass. The square form of the room is brought into the round form of this opening by very flat elliptical pendentives. The space under the elliptical arch on the north side of the chamber is occupied by the Speaker's platform, behind which the wall is wainscoted to the gallery level. The space above is occupied by the magnificent mural painting by the distinguished artist Edwin Howland Blashfield. It represents "The State of Wisconsin: Its Past, Present, and Future." The space under each of the remaining three elliptical arches is occupied by galleries supported by Breche Violette Italian marble columns, which separate the main auditorium from the entrance lobby and corridors, and in turn give direct access to the loggia on the west front, and the Assembly Parlour on the south side of the wing. The walls of the Assembly Chamber are of the spring of the arches, above which the walls and ceiling are of plaster, decorated with appropriate low tones to harmonize with the marble and Mr. Blashfield's painting. The room is approached through a lobby, the walls of which are lined with Botticino Italian marble, with matched panels in the central portion of Light Sienna marble. The whole length of the lobby is brought into correct proportion by the introduction of columns of Royal Tennessee marble. The central portion of the lobby opens into the main stair hall through three rich electro-plated cast-iron grilles. The Assembly Reception Room is finished in Circassian walnut panelling, with mantels at the ends of Sienna marble, and floor of marble tile. The floor tiling for the halls, corridors, and ante-rooms throughout is in carefully studied mosaic of limestones and coloured marbles in large slabs, and the electric light fixtures and ironmongery throughout have been specially designed as part of the architectural enrichment of the building. The east wing contains on the second floor the Supreme Court Room (B), and a suite of offices for the judges, and on the first floor the Executive Chamber and Attorney-General's Department. On the third floor is situated the library, connected by elevators and stairs with the corridor surrounding the Supreme Court Room, communicating with the judge's offices and also by elevator with the Attorney-General's Department on the first floor. A reading room is also provided for the general public, in connection with the library. A room 46ft. by 40ft. is provided in the attic, the rest of the attic being given up to storage purposes. The Supreme Court Room is square in plan, its dimensions being 42ft. by 42ft. by 30ft. high. It is lighted by a large central ceiling light of low-toned leaded glass work, set in a flat coffered ceiling—this to prevent reverberation. The court room itself will be finished in two shades of Botticino Italian marble, the pilasters being of fine Italian Coralline marble with small columns of Sienna behind the judge's platform. Other marbles of decorative colour are to be introduced where they will produce architectural effect. Space is provided for decorating this room with four mural paintings. The Executive Chamber, with its lobby, is most carefully studied to secure the greatest amount of dignity and decorative effect. The design for this room is in the Venetian Renaissance style, and it is arranged to introduce in the wall panels three historic mural paintings representing prominent events in the early history of the State. The building is designed to stand on a terrace or platform, and thus equalise the differences in the level of the park, and give the building a greater appearance of symmetry.

In describing the recent fire at Messrs. McCorquodale's printing works at Euston, it was noted that the spread of the fire was prevented by the intervention of fireproof doors. We are informed that the St. Pancras Ironwork Co. supplied the double iron doors which rendered this efficient service.

The sewage scheme which involves the purchase of 600 acres of land at Templenewsam is being expedited by the Leeds Corporation. The price to be paid for the land was fixed by arbitration, and it is announced that the award of the arbitrators is for the payment by the corporation of £149,644. It is estimated that the total cost of carrying out the project will be about one million and a quarter sterling.

* * *

A stained glass window in memory of the Rev. Sydney Orpwood Miller, M.A., was recently unveiled and dedicated in St. John's Church, Horninglow. The window, which is placed in the east end of the south aisle, consists of two large lights, which represent standing figures of St. John and St. Paul. Messrs. Wm. Pearce, Ltd., Bridge Street, Birmingham, were the makers. The cost, about £100, was borne by the parishioners.

Messrs. E. A. Roome and Co., builders and contractors, of 36, Basinghall Street, E.C., and Crown Works, Homerton, N.E., have secured the contract to pull down and rebuild the "Prince Arthur" public house at Lee, for Messrs. Watney, Coombe, Reid and Co., Ltd., under the supervision of Mr. M. T. Saunders, architect and surveyor.

MAIN HALL, COLLEGE OF THE CITY OF NEW YORK. GEORGE B. POST AND SONS, ARCHITECTS.

The strength of the design and the vigour of scale are conspicuous in this view from the garden side.

THE ATHENÆUM CLUB REDECORATED.

The completion of the new scheme of decoration at the Athenæum Club happily coincided with the recent burst of genuine summer, and no building in Pall Mall during that all too brief period was more attuned to a really blue sky and dazzling sunlight than Decimus Burton's club-house. The work, it is interesting to note, has been carried out under the supervision of the Decoration Committee, consisting of Sir Edward J. Poynter, P.R.A., Sir L. Alma-Tadema, R.A., and Mr. Arthur Lucas. This distinguished body has been responsible for the internal decorations of the club for the last 15 or 16 years, special designs having been presented by the President of the Royal Academy and Sir L. Alma-Tadema. The committee have reason to be satisfied with the success achieved in this instance.

The club in its new dress will be a useful lesson of what a little colour can effect where a too-long tolerated tradition has accustomed us to a monotony of unrelieved stonework or to the more deadening results of stucco. You cannot now walk down Pall Mall without noting the striking contrast between the refreshing harmony of the Athenæum and the cement-washed plaster work of the club confronting it, or the gloomy paint of the Travellers' next door.

In the new scheme the portico, in white and broken white, and the windows, stand out against a background of drab tints, the basement, ground, and first floors, being marked by a scale of three ascending tones; the white spaces are further relieved by the olive green railings of the balcony running round the building, with the pleasing little angle tripods which now show to splendid advantage the delicacy of touch of the original designer of the club. So, too, even with such minor matters as the bronze wreaths on the balustrading to the portico, over which the presiding bronze figure of Athena (formerly in white) completes an harmonious whole, which obtains for its final setting a touch of "living green" in the glimpse of garden that is not without its effect on the amenity of Pall Mall.

It is, however, in the reproduction of the Parthenon frieze, so fitting a finish to the club, that the most noteworthy change has been wrought, for we now see the figures in pure white picked out on a background of ochre, and to many of us the effect will be of having seen the figures for the first time. This is a revolutionary piece of decoration, no doubt, considered in regard to London street architecture. But we must remember that so even the Parthenon must have looked decked out in red and blue, difficult though it may be to forget that it was never one solid mass of pure white marble. No! not even the famous frieze. The frieze of the Athenæum does not of course reproduce anything of the actual treatment of the Greek original—our climate, however propitious for a few days, would not run to that—but it is a departure from latter-day conventions that must go back to Athens for its inspiration.

The work has been carried out by the Decoration Committee by direct labour.

Enquiries Answered.

Correspondents are particularly requested to be as brief as possible. The querist's name and address must always be given, not necessarily for publication.

The Editor is willing to answer enquiries from readers who require information on architectural, constructional, or legal matters. Such information must be regarded as the gratuitous advice or information of a friend, and not as the professional opinion of one who holds himself out as possessing expert knowledge on the subject in question. The Editor will, however, avail himsel. of the assistance of a large staff of experts in the matters above mentioned, but enquiries sent must be on the express understanding that he is not to be held responsible for any delays, mistakes, inaccuracies, or negligences which may occur.

Enquirers whose questions involve possible legal proceedings are strongly urged to consult their solicitors before taking definite steps in regard thereto.

Answers by post will be sent if the enquiry is accompanied by a postal order for 1s. made payable to Technical Journals, Ltd., and crossed, and a stamped addressed envelope. Such enquiries must be marked "Answers by Post" on the outside cover.

This fee of 1s. required for answers by post is in no case to be regarded as payment for the answer given, but merely as a registration fee to meet the extra clerical and other expenses incurred in dealing with these special replies.

The Editor also reserves the right of refusing to reply to any question that he may deem to be unreasonable or unsuitable and it must be understood that both question and reply will, as a rule, be published in these columns

Buying Timber.

LONDON, N.—BOAZ writes: "(1) Is there a book published giving brands, ports of shipment, etc., and means of identifying quality, etc., from brand marks? (2) At what cost, and where, can I purchase a good map of the Baltic Sea, showing ports? (3) What is the routine in clearing timber from docks, and what are the detailed dock charges, rents, landing dues, etc.?"

—(1) A book of the description referred to is being prepared at 84, Leadenhall Street, and will be published about October. (2) It will contain the map enquired for. (3) The secretary of the Port of London Authority will supply a book giving in detail the landing and piling charges on timber. If asking him for it, name the Surrey Commercial Docks in particular. The book probably costs 6d. or 1s. The charges vary very much, in accordance with the nature and quantity of the stuff, but usually run between 10s. and 13s. per standard, when the various small extras are included. Merchants, in selling timber landed in docks, do so, as a rule, free of all charges to buyer, except the 6d. per delivery which the Dock Co. charge the carman when a load of less than one standard is removed. The merchant, in issuing transfer or delivery warrant, usually specifies thereon that goods are to be sent free to buyer for 14 or 28 days. Rent on softwoods is 1s. per standard per month if piled in the open, or 1s. 6d. if piled under cover. This is quite distinct from the landing and piling charges. J. DAVIES.

Powers as to Sanitary Accommodation.

YORKSHIRE.—B. T. writes: "In some old property, middens and privies have been condemned by the medical officer of health, who states that w.c.'s are to be provided. The owner's offer to provide earth-closets, such as are being allowed in new buildings now being erected in the town, has been rejected, though the by-laws seem to permit earth-closets. The houses have w.c.'s on the first floor, so that the earth-closets are not absolutely necessary. Alternatively, could the owner do away with the middens altogether?"

—If there is any provision on the points raised in any local Act of Parliament relating to Scarborough, that provision will be the determining factor. The general law is, according to the latest case on the matter, that if a local authority thinks that a w.c. is necessary, it may require one to be constructed; and if the owner of the house thinks that the w.c. is unnecessary, he may appeal to the Local Government Board (*Sutcliffe* v. *Sowerby Bridge Urban District Council*, 73, J., P., 385; Pub. Health Act, 1875, S. 36). If, therefore, the Local Government Board can be satisfied that an earth closet would be sufficient, or that there are sufficient w.c.'s in the house, an appeal to them would no doubt be successful. Perhaps even if the local authority were informed that the querist was prepared to do away altogether with the privy, they might withdraw their notice and save the necessity of appealing. But the querist cannot neglect the notice, because the local authority may do the work themselves. BARRISTER.

Dampness of Brick and Flint Wall.

BURY ST. EDMUNDS.—INQUISITOR writes: "In a brick-and-flint-faced building, which probably has no damp-course, a damp fungus forms, both on internal and external walls, at places where there is any woodwork. What is the remedy?"

—The age of the building is not stated—whether just erected, or whether built some few years ago—and the nature of the soil would make some difference. There is, however, not much doubt but that the damp rising in the wall is due to the absence of a damp-proof course, and nothing but the insertion of one will prove entirely effective; but if air-bricks are put in at intervals of 5ft. or so round the base, they will help to keep the walls dry, and prevent dry-rot in the ground floors. It may be that the mortar is partly in fault, as poor mortar is always more apt to convey moisture to the interior of a wall. Damp may be prevented from coming through on exterior face by using one of the soluble silicate solutions. All infected woodwork should be removed, and the remainder washed over with a solution of copper sulphate (bluestone).

HENRY ADAMS.

Fee for Design.

Provinces.—Quis writes: "What would be a fair fee to charge for a plan prepared for a speculating builder; and what would be a fair charge for a tracing for the district council?"

—In referring to a "plan," the querist presumably means a design. If so, there is no apparent reason why the speculating builder should be differentiated from any other client. Two per cent. on the cost would be a fair charge for design and working drawings alone. If, however, an ordinary form of plan has been merely drawn out for the builder's use it is a question of draughtsmanship only, and five guineas would probably meet the case. The copy on linen for the District Council would be worth about one guinea.

G.

Remedy for Leaky Tanks.

Lancashire.—J. R. G. writes: "We have some water tanks which are built in cement concrete and finished inside with cement, which are leaking very badly. We do not want to float them in cement again, if there is any other means of stopping the leakage."

—We cannot suggest any remedy for such leaky tanks except the coating of them inside with a bitumen sheeting, of which there are several makes on the market. The tanks are probably leaky because of cracks in the concrete produced by temperature stresses, and these cracks will continually open, no matter what precautions are taken. Therefore, the only thing is to provide a flexible coating that is independent of the tank, and will not be cracked by the concrete opening.

Buildings to Sketch and Measure in Newbury.

In answer to "E. S." (London, N.W.), Newbury itself contains the "Old Cloth Hall" (restored), and a very interesting building called "The Storehouse," besides several good examples of old brickwork. About a mile to the north is Shaw House (1581), and near by is the ruined Early Perpendicular Gate-house of Donnington Castle. About four miles to the west, at Hampstead Marshall, are the splendid series of gate piers—all that remains of the former mansion. About 10 miles in this direction, near Hungerford, is the noble house Littlecote, Wilts, built by the Darrells in the 16th century. At Aldermaston, eight miles to the east, are the entrance lodges of a 17th century house (since rebuilt). About nine miles to the north-east is Aldworth Church, containing a very fine series of Decorated altar tombs of the de la Beche family. Further afield, though strictly speaking, within cycling distance, are the exceedingly interesting towns of Abingdon (20 miles), with its fine town hall, church. and almshouses; Dorchester (20 miles), with its fine Abbey Church, and the delightful village of Ewelme with its 15th century church and cloistered almshouses. The picturesque villages of Blewbury, East Hagbourne, Steventon, and East Hendred, lying close together at a distance of about 15 miles from Newbury, form delightful sketching grounds. At East Hagbourne, the church, village cross, and several half-timbered bricknogged cottages claim attention; Steventon has two very interesting timber and plaster houses, and at East Hendred is a Perpendicular wayside chapel (disused), and an Elizabethan farmhouse.

G.

Quality of Basswood.

Wimbledon. — Columba writes: "Basswood of best quality (left untouched from the plane) is specified for the joinery of a house now being completed. Is it impossible to get this wood in a uniform shade of light brown colour? because what the contractor is using is very varied in hue—some of it being white, like deal, often with very pronounced greenish streaks in it, some of a greenish-yellow tint, and other light brown. Portions of it, too, have black streaks and marks appearing here and there. (1) Can this rightly be called 'Best quality Basswood?' and (2) is it at all likely (if left unstained or polished) to tone down in time to a uniform colour? Strictly speaking, is Basswood obtained from the American Tulip tree (Liriodendron tulipifera) as well as from the American Lime (Tilia Americana) or only from the latter?"

—Basswood is subject to these variations of colour, even in the highest qualities. Prime in this connection means free from knots and splits, and in the trade the differing shades are not regarded as ground for complaint. It is therefore not suitable for joinery unless covered by paint or other decoration to such an extent as to make the original colours invisible. There is no likelihood of its becoming more uniform. It is obtained from the American Tulip tree.

J. Davies.

Combined Drainage.

London, E.—Anglo writes: "Will you kindly inform me through the columns of your valuable paper whether, in your opinion, the whole, or the portion marked B, in the annexed rough plan [not reproduced] of a combined system of drainage, situated outside the metropolis under an urban district council, is legally a sewer repairable by the parish? The property was built some 56 years ago. There is no plan of any part or parts of this system of drainage at the Town Hall, and the Urban District Council have several times at their own expense cleansed the pipes when they were choked up. If you consider the pipes a sewer, will you kindly mention the decision on which you base your opinion?"

—We are of opinion that the drainage system shown from the point where it receives the sewage of the second house (No. 5) is a sewer, and repairable by the local authority (see Travis v. Uttley (1894) I.Q.B., 233). There are numerous other cases bearing on minor aspects, but to the same effect.

THE HOUSING AND TOWN PLANNING BILL IN PARLIAMENT.

The proceedings in Committee on the Housing and Town Planning Bill having been fully reported in the daily Press, it is only necessary to preserve here a summarised record of the proceedings.

The House went into Committee on Monday, August 30th, Mr. Emmott in the chair.

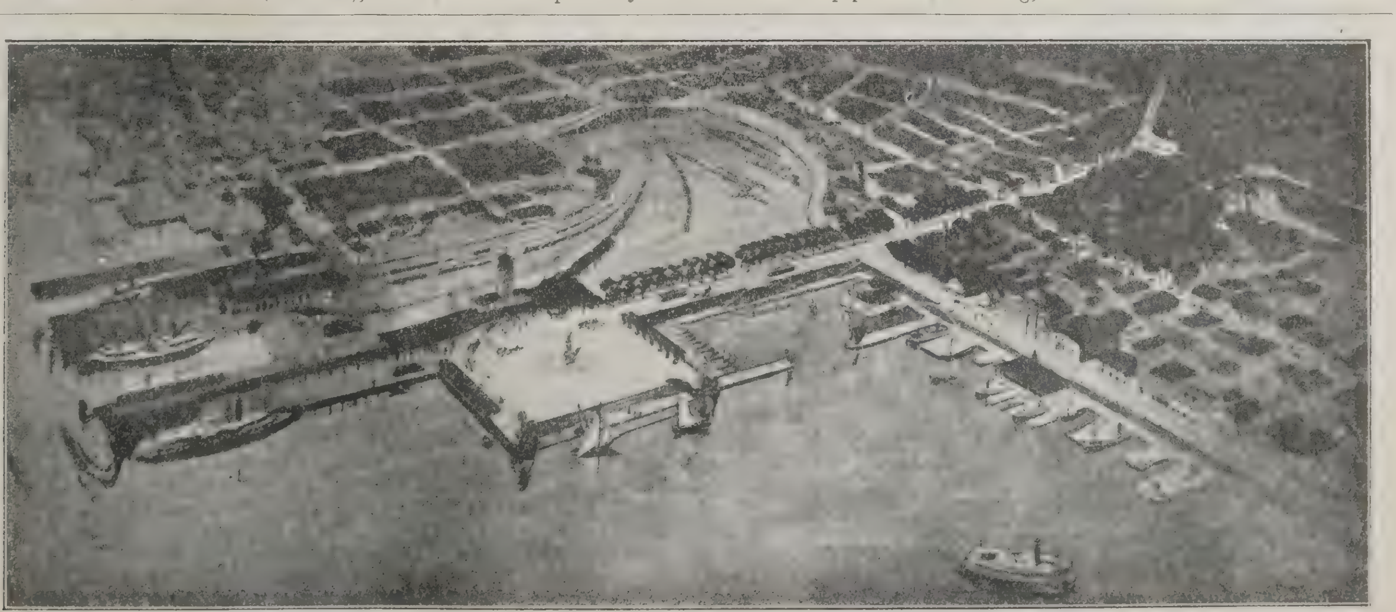
Clause 1 reads: "Part III. of the Housing of the Working Classes Act, 1890 (in this part of this Act referred to as the principal Act) shall, after the commencement of this Act, extend to and take effect in every urban or rural district, or other place for which it has not been adopted, as if it had been so adopted."

Sir F. Banbury moved the omission of the clause, contending that it involved the extinction of the local authorities so far as this part of the work was concerned, and invested the President of the Local Government Board with autocratic authority.

Mr. W. Guinness said that we must depend for better housing on private enterprise controlled and encouraged by the local authorities. Builders at present reckoned on the local authorities not competing; but under this Bill they would put up houses regardless of the heavy loss thrown on the rates, while building in the towns would be checked. It was a dangerous principle to start compulsion where the central authority did not make any grant.

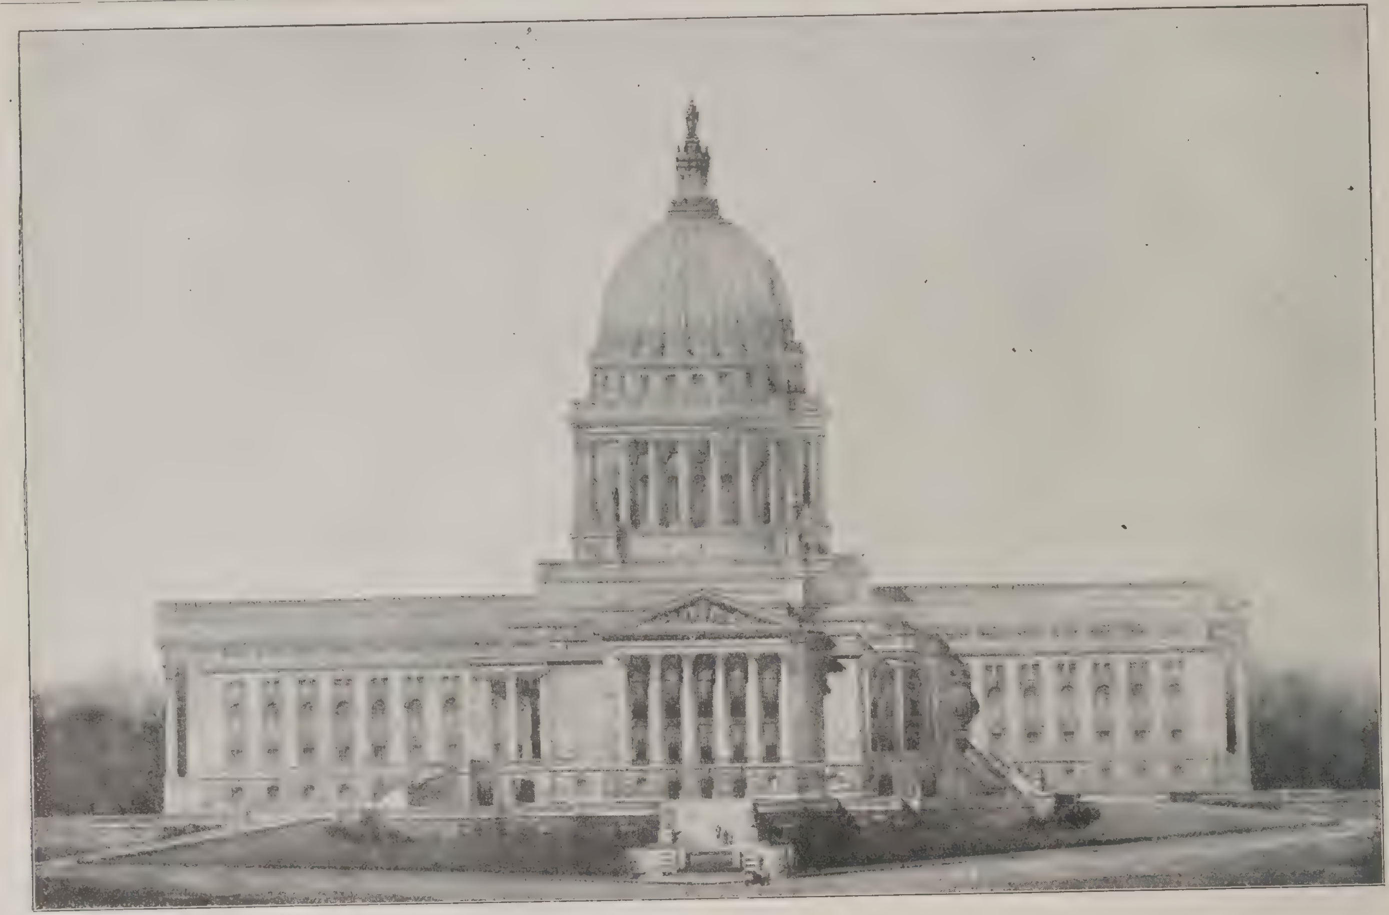
Sir F. Powell, as one who had been long interested in the subject of public health, supported the clause, as he thought the time had come when the House should take another step in advance.

Mr. Burns said that the clause would have exactly the opposite effect to that anticipated by Sir F. Banbury. The object was to enable the 671 rural district councils to cut themselves free from the shackles of the county councils, and, as far as the initiation of housing was concerned, to place themselves under the supervision of the Local Government Board. It would allow these authorities to include in their ordinary sanitary and public health duties the work of housing, which was now denied them. The



SUGGESTED IMPROVEMENTS, NEWPORT HARBOUR, RHODE ISLAND. GEORGE B. POST AND SONS, ARCHITECTS.

This is regarded as a magnificent specimen of city planning of a sort too seldom ventured upon by architects,



WISCONSIN STATE CAPITOL. GEORGE B. POST AND SONS, ARCHITECTS.

This building, which is now in course of construction, is regarded as a public monument of the first importance, and is expected to rank as the greatest work of American architecture yet produced.

conditions in many of the rural districts were such that anything that would stimulate competition between private enterprise and the public authorities in the matter of providing houses would be an advantage. All the clauses did was to give the rural district councils the same powers of grappling with the housing problem as were exercised by the London County Council.

Viscount Morpeth thought the clause futile, as its operation depended on money which the rural councils could not raise..

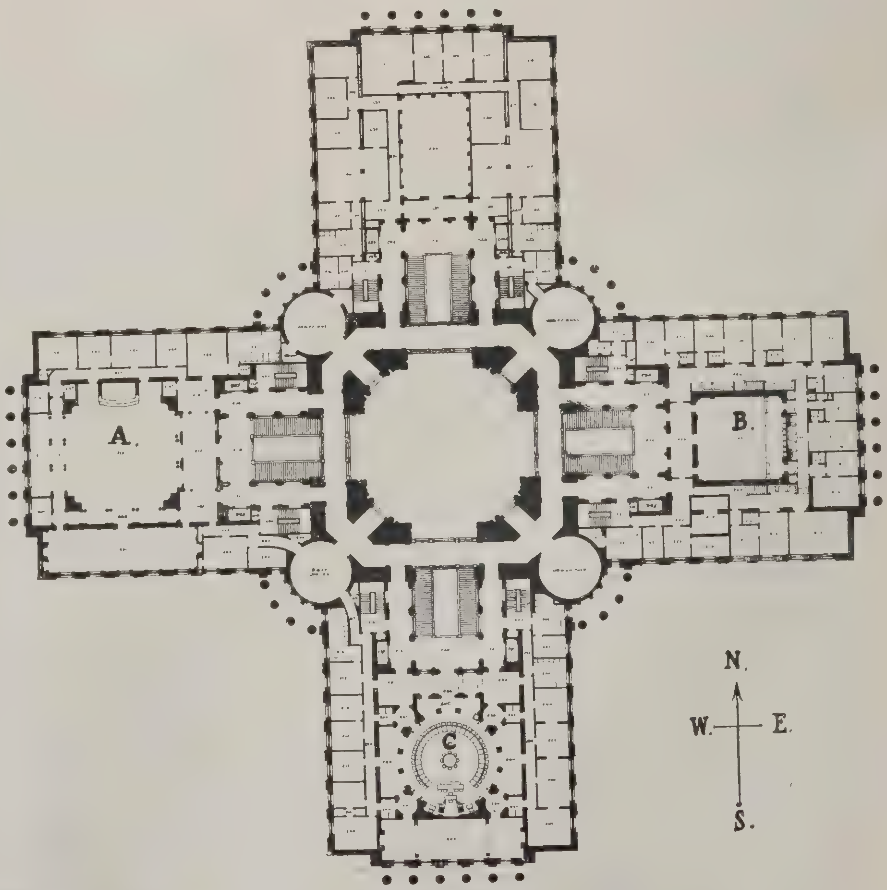
Mr. Lane-Fox did not object to the general principle of the Bill, which he would do his best to help, but he protested against increase of rates imposed against the wishes of the people of a district.

Mr. Munro Ferguson, Sir C. Schwann, and Mr. Adkins supported the clause, and Mr. Carlile opposed it.

On a division, the clause was carried by 132 against 19.

Clause 2 is as follows: (1) A local authority may be authorised to purchase land compulsorily for the purposes of Part III. of the principal Act, by means of an order submitted to the Local Government Board, and confirmed by the Board in accordance with the first schedule to this Act. (2) The procedure under this section for the compulsory purchase of land shall be substituted for the procedure for the same purpose under section 176 of the Public Health Act, 1875, as applied by sub-section (1) of section 57 of the principal Act. (3) A local authority may, with the consent of and subject to any conditions imposed by the Local Government Board, acquire land by agreement for the purposes of Part III. of the principal Act, notwithstanding that the land is not immediately required for those purposes."

Mr. Cave moved to omit sub-section (1). He took exception to the effect that land could be taken by compulsion without the sanction of a provisional order requiring confirmation by Parliament, while, in the ascertainment of the amount of compensation to be paid, no owner of property would



WISCONSIN STATE CAPITOL. PLAN.

The design (the conditions of the competition required it to be cruciform in plan) is radically different from that of any other existing State capitol. The various departments are brought into close intercommunication, and yet are in separate wings of the building. (See page. 183.)

have a right to claim a reference to a jury. He was also strongly opposed to the provisions that any question of disputed compensation should be determined by a single arbitrator appointed by the Local Government Board, and that, unless the L.G.B. agreed, the parties should not be represented before the arbitrator by counsel.

Mr. Munro Ferguson thought that the cost of the introduction of counsel and witnesses would be enormous, and was not in the least necessary.

Mr. Holt thought that there should be independent enquiry before anyone's land was compulsorily taken. The L.G.B. might order compulsory purchase notwithstanding a report unfavourable to that course.

Mr. Lyttelton said that the schedule would enable the L.G.B. to disregard the report of their own arbiter, and sanction compulsory purchase in spite of his report. That was a very strong power, and ought not to be granted. The proceeding the Government laid down was not an arbitration but a valuation.

Mr. W. Guinness, Mr. Morrell, Lord R. Cecil, and Sir F. Banbury having spoken, Mr. Burns said that it was in the interest of the local authority to save money from being spent on legal procedure, so that more money should be available to buy more or better land for more or better cottages.

Mr. Cave pressed the amendment, because he felt that to provide that the Board should nominate the person to fix the price was a gross injustice.

The amendment was lost, the numbers being 146 against 32.

Mr. Brodie moved the insertion of words permitting the local authority to hold land purchased compulsorily, as it would be wise to encourage local authorities to acquire land several years in advance.

Mr. Burns said that the Government could not accept the amendment, as the Bill gave local authorities good and proper opportunities of acquiring land within the purview of reasonably expected requirements. In order to safeguard local authorities from too ambitious enterprises in land speculation, it was advisable to be cautious as to the powers granted them. The L.C.C. had bought 200 acres at Tottenham, of which only a portion was immediately needed for housing. The remainder was being held, with the consent of the Local Government Board. The same thing would happen in the case of land taken by compulsion.

Lord Morpeth, retorting, thought that the holding up of land by authorities would be worse than if it were in the hands of private owners, as the former would escape the increment tax.

The amendment was withdrawn.

Mr. Munro Ferguson moved to omit from the first sub-section the words "Part III. of the principal Act," and to insert "the Housing Acts." The Scottish local authorities thought that the sub-section would make it possible for them to acquire land for sites for lodging houses only.

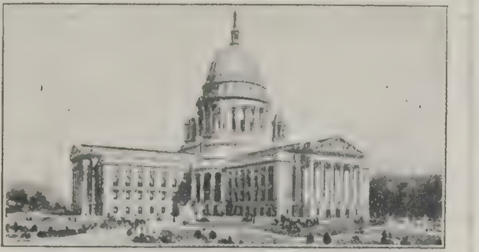
Mr. Burns, in the absence of the Lord Advocate, could not accept the amendment, which was withdrawn.

Sir F. Banbury moved to leave out all the words of sub-section (1) after "principal Act." He objected to private property being dealt with by a sort of Star Chamber.

Mr. Burns objected to the amendment, which was withdrawn.

Mr. Cave moved to add to the sub-section the words, "but this provision shall not apply to any common land within the meaning of the Inclosure Acts, 1845 to 1899, or to any open space used by the public for purposes of recreation," but withdrew his amendment after Mr. Burns had protested that these interests were adequately safeguarded.

Mr. McArthur moved to add the following at the end of sub-section (1): "But this provision shall not apply to any land which, at the date of the order, has been acquired by the owners thereof for the purposes of a railway, dock, canal, water, or other public undertaking." Such bodies had certain powers conferred on them by Acts of Parliament, and he held that it was monstrous that a local authority with the L.G.B. behind it should be able to deprive them of those powers.



WISCONSIN STATE CAPITOL: PERSPECTIVE VIEW.

Mr. Burns said the Government saw no reason why land owned by these companies should be treated differently from the land of other owners. A railway or other company which held land in excess of its requirements, should not be allowed to hold it in perpetuity as against the public needs.

Mr. Lyttelton, Colonel Lockwood, and Mr. Holt supported the amendment, which was opposed by Mr. John Ward, and was lost—33 for, 167 against.

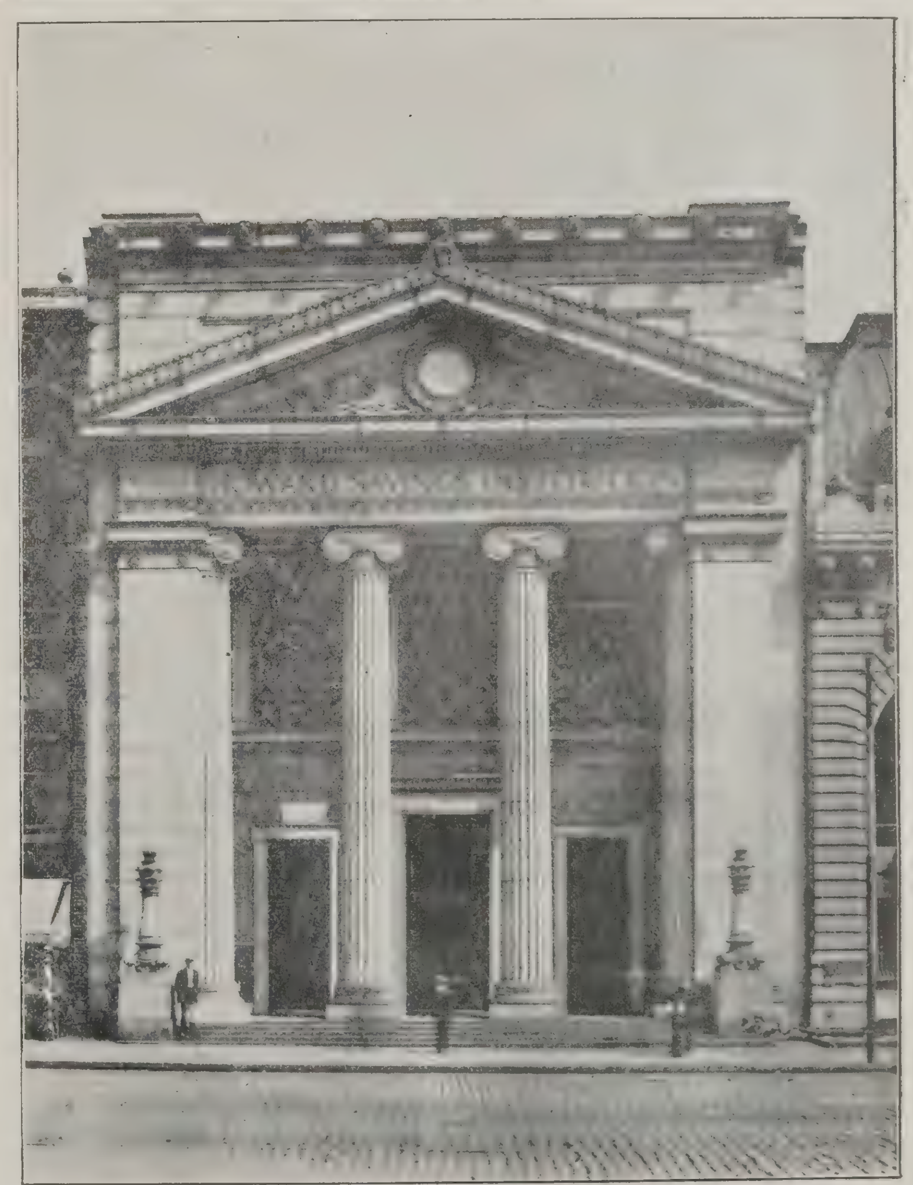
It being now 7.30, the closure was enforced with regard to the other clauses to which private amendments had been set down.

Mr. Burns moved an amendment, which was agreed to, to sub-section (3) of clause 15, which now provides that, on default of the landlord, the local authority may execute repairs and recover the expenses incurred by them from the landlord as a civil debt, or order the expenses to be payable by annual instalments "within a period not exceeding that of the interest of the landlord in the house nor in any case five years."

The remaining clauses, which need not be mentioned in detail, as they possess but little building interest, were carried without much opposition, except clause 30, which deals with quinquennial survey and register. On this Mr. Cave moved to omit the first sub-section, which provides that every local authority shall make an inspection and survey of every house in its district below a certain rateable value, and register the result of such survey, with particulars. He regarded this as a serious blot on the Bill.

After a somewhat protracted debate, the voting resulted as follows: For the sub-section, 75; against, 121.

On clause 44, prohibition of back-to-back houses, Mr. Burns moved to add at the end of the clause: "Provided that nothing in this section (a) shall prevent the erection or use of a house containing several tenements in which the tenements are placed back to back, if the medical officer of health for the district certifies that the several tenements



THE HOWARD SAVINGS INSTITUTION. NEWARK, NEW JERSEY. GEORGE B. POST AND SONS, ARCHITECTS.

In this building all the facade, and also the interior, are of white marble. In design and construction, the building is peculiar and original. (For discription see page 182.)

are so constructed and arranged as to secure effective ventilation of all habitable rooms in every tenement; or (b) shall apply to houses abutting on any streets the plans whereof have been approved by the local authority before May 1st, 1909, in any borough or district in which, at the passing of this Act, any local Act or by-laws are in force permitting the erection of back-to-back houses."

The numbers were: For the amendment, 121; against, 64. On the question that the clause as amended stand part of the Bill, the voting was: For the clause, 115; against, 69.

On Tuesday, August 31st, the House again went into Committee, when Part II., the town-planning part of the Bill, was discussed.

Mr. J. W. Cleland moved to omit the words "the Local Government Board may authorise," at the beginning of sub-section (2), which reads: "The Local Government Board may authorise a local authority within the meaning of this part of this Act, to prepare such a town planning scheme with reference to any land within or in the neighbourhood of their area, if the authority satisfy the Board that there is a *primâ facie* case for making such a scheme, or may authorise a local authority to adopt, with or without any modifications, any such scheme proposed by all or any of the owners, or any land with respect to which the local authority might themselves have been authorised to prepare a scheme." Mr. Cleland said that whereas the local authority must obtain the permission of the L.G.B. before it could prepare a town-planning scheme, a private owner or syndicate was under no such obligation.

Mr. Burns defended the clause, and the amendment was withdrawn.

Sir F. Banbury moved an amendment which stood in the name of Mr. McArthur, excepting from the operation of the clause land acquired by any corporation or company for the purposes of a railway, dock, water, or other undertaking.

The amendment was lost—41 for, 176 against.

Mr. Mitchell-Thomson's proposal to omit "or in the neighbourhood of," in order to prevent friction between lôcal authorities, was withdrawn.

Sir F. Banbury moved the omission from sub-section 3 of the words, "a piece of land already built upon," so as to take it out of the power of a local authority "who fancied that they were endowed with great architectural ability practically to demolish the better part of a town."

The amendment was lost—49 against 196.

Mr. Cave's amendment to sub-section 7, designed to prevent the L.G.B. having power to decide, without appeal, whether or not land was likely to be used for building purposes, was lost—51 against 195.

At this stage the closure was put in force.

Mr. Burns's amendment to clause 57, to omit the words, "Nevertheless, no such compensation shall be paid till such time as the loss has actually occurred"—with reference to compensation to any person whose property is injuriously affected by the operation of a town-planning scheme—was accepted.

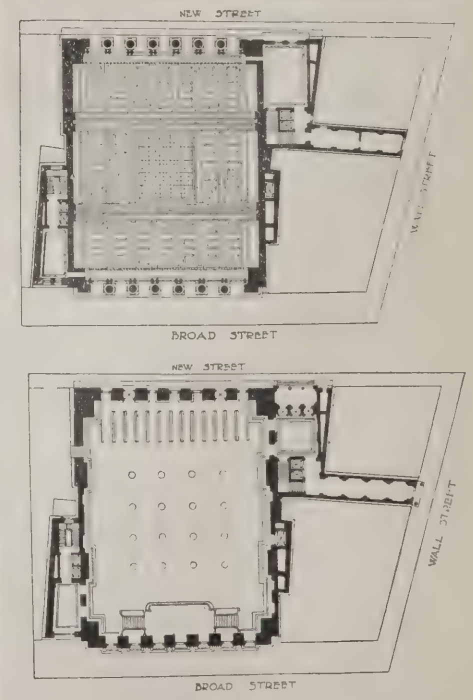
Lord R. Cecil, on behalf of Mr. Cave, moved to omit from sub-section 2 the words "or after such other time as the L.G.B. may fix for the purpose," and to insert, "if in the opinion of the Court such work was done with a view to obtaining or increasing compensation under this Act"—the idea being that a time limitation should not be fixed unless there was some ground for thinking that work had been done with a view to increasing the compensation.

Mr. Burns's chief objection to the amendment seemed to be that it substituted a court of law as the deciding authority, instead of the L.G.B.

The amendment was withdrawn.

With regard to sub-section (3), Mr. W. Guinness moved the substitution of the words: "In determining the amount of compensation under this section, regard shall be had to the extent to which lands and hereditaments belonging to the same proprietor may be benefited by the scheme."

Some remarks in favour of this amendment by Lord R. Cecil brought out from Mr. Burns a terse statement of "what the Government contemplated in a town-planning scheme." "Roughly," he said, "it was this. Whereas in the past, without any scheme, roads had been badly laid, of insufficient width, and without any relationship to other roads, the Government by this Bill gave the responsible local authority power to initiate a town-planning scheme, so that private owners would improve their own properties instead of acting to their individual or collective detriment. In nine cases out of ten the scheme would consist less of proposals to buy land than of assisting private owners to lay out their properties beneficially." In the experience he had had of town planning and housing estates, he had been surprised, speaking generally, at the way in which all the interests concerned had co-operated to make the best of the



NEW YORK STOCK EXCHANGE. PLAN OF BOARDROOM FLOOR.
The peculiar features of this plan are detailed on p. 18

situation, and he was convinced that the practical instinct peculiar to the English people in matters of this kind would so prevail that all questions of conflicting interests would be reduced to a minimum. The amendment was lost—36 against 184.

Mr. Cave moved to amend sub-section 4 by substituting arbitration instead of the authority of the L.G.B. in determining any question as to whether any property is injuriously affected or increased in value.

The Attorney-General opposed the amendment on the ground that the machinery of arbitration would be cumbrous and costly out of all proportion to the value of the issues that would ordinarily be involved.

The discussion, in which Mr. Lyttelton, Mr. Burns, Viscount Morpeth, and Lord R. Cecil took part, lasted until the closure came into operation, when 57 voted for the amendment, and 194 against.

Mr. Burns moved the insertion of the following in clause 58: "(2) Property shall not be deemed to be injuriously affected so as to give rise to any claim for compensation under this part of the Act by reason of the operations of any provisions inserted in a town-planning scheme, which, with a view to securing the amenity of the area included in the scheme or any part thereof, prescribe the space about buildings or limit the number of buildings to be erected, or prescribe the height or character of buildings, and which the Local Government Board, having regard to the nature and situation of the land affected by the provisions, consider reasonable for the purpose."

The voting was—for the amendment, 206; against, 50.

This concluded the clauses as they stood in the Bill. New clauses, on "Saving of Sites of Ancient Monuments, etc.," and "Provisions as to commons and open spaces," were added to the Bill. The clause "Provisions as to land in neighbourhood of royal palaces or parks" was challenged by the Labour Party, whose objection was defeated by 194 against 50.

All the schedules were adopted, only schedules 1 and 4 exciting opposition.

London Suburbs.

Richmond.

There is no place in Greater London which has so plainly a character of its own as Richmond. It is indeed so marked that the name of suburb may, perhaps, jar a little upon the ear of its inhabitants. It has many advantages: a matchless view from its hill, perhaps the most characteristic piece of scenery in England; a river specially fitted for recreation, and two fine parks, one of them on a very large scale. As a residential neighbourhood, it cannot be separated from its neighbour, Twickenham, the contrast between the two being somewhat marked, the latter lying upon flat land by the river. Horace Walpole has immortalised it in his letters; Strawberry Hill, his "little Gothic castle," a curious fancy in an age of "classic" building, still stands, and its river banks are still unspoilt: it has room to spread to the northward into Middlesex. Richmond, however, is somewhat circumscribed by its very picturesqueness; its parks, commons, and river hem it in, and its only possible expansion is towards Sheen; for Kew, which is practically its suburb, is itself prevented from spreading by its beautiful Royal gardens.

Architecturally, Richmond possesses a quaint relic of older times in its Green, bordered by some excellent specimens of early eighteenth century architecture known as Maid of Honour Row, many pleasant villas of "the day before yesterday" period, and the celebrated gateway, and some other remains of its Royal Palace. The gateway is a large and bold Tudor arch of stone in a red-brick wall. It gives entrance to a space formerly called the Wardrobe Court. Passing inside we find the zig-zag designs of black running through the red Tudor walls in marked contrast to the heavy sash windows introduced late in the seventeenth century. The Palace originally extended nearly to the river; it was celebrated for its many turrets and pinnacles and vanes, the latter fashioned into the King's arms, and, as an old writer tells us, "payntid and gilte with riche gold and azure," and when they creaked, "pleasant to see and hear in a wyndy day."

Thus comparatively limited, long associated with royal residences—of which two still survive in the Park—Richmond is at once popular and select. Where modern work is seen it is generally of red brick, and is limited to villas, which are of the type nearly universal in the last twenty years. Many older styles, however, may be found on the slopes of the hill. The town properly so-called is bright with shops, and as usual some of the best buildings are its banks. It is curious that two distinct sets of complaints are heard from residents in this pleasant town; one, that owing to trains, tramways, motors, and modern changes generally, the number of visitors is so great that the place is spoilt; the other, that for a place so near "town" the means of reaching it are quite inadequate. The main attraction of Richmond is undoubtedly its beautiful river, and this, with Ham House on one side, and Hampton Court on the other, is unique. In regard to possible new buildings on the Middlesex shore, it should be said that to preserve its river scenery is essential to the popularity and, consequently, the prosperity of the place. Its newest developments, whilst "attractive residences," have not yet given us that new style which is to meet all modern wants and settle all questions, whether of taste or comfort. But perhaps it may never come.

Proposed New Works.

ABERDEEN.—The addition which is to be made to the Royal Infirmary Buildings is to occupy a site upon which at present stand a block of houses immediately opposite the main Infirmary buildings, and forming the square between Woolmanhill, St. Andrew Street, North St. Andrew Street, and John Street. A commencement has been made with the demolition of the houses preparatory to the erection of the new block, in which will be located the outdoor patient department, the dispensary, a few beds for casualty cases, a theatre, etc. There will also be a reception hall in the block.

BASINGWERK (WALES).—The Chester Society of Natural Science, Literature, and Art, are endeavouring to prevail upon the authorities to preserve the ruined abbey of Basingwerk. The abbey, of which there are still considerable remains, stands on rising ground near Holywell station. It is believed to have been built in the twelfth century, and was then under the patronage of Ranulph Earl of Chester.

BATLEY.—It has been proposed to erect a new temperance hall at an estimated cost of £7,000. There appears to be slight probability of the scheme proceeding at present, however, as the sum of £1,000 as a donation is required before the committee which has the matter under consideration deems itself justified in authorising a commencement.

BATLEY.—The condition of the Parish Church having excited grave misgivings as to its safety, it having been discovered recently that the oak beams supporting the roof of the nave and chancel were in a dangerous condition owing to dry rot, it has been decided that a temporary roof shall be fixed in place of the one that has been removed. A scheme for the erection of an entirely new church has been initiated.

BENTLEY.—A Local Government Board inquiry has been held into an application by the Doncaster Rural District Council for power to borrow an additional £3,000 for sewage disposal work in the parish of Bentley-with-Arksey.

BIRKENHEAD.—The Corporation have at present under consideration a plan which has been prepared by Mr. T. T. Rees, architect, of Liverpool, for the improvement of the foreshore between Rock Ferry and New Ferry. This involves the reclamation of a large piece of the foreshore, the construction of a semi-circular road between the two points mentioned, and some minor alterations and additions.

BRIGHTON.—The Town Council have under consideration a proposal for the provision of a winter garden at the Brighton Aquarium. It is suggested that a large hall be erected on the site of the present terrace.

COATBRIDGE.—There are signs of improvement in the building trade which has been at a very low ebb for some years. At the local Dean of Guild Court, Messrs. Stewart and Lloyds, tube manufacturers, have presented plans for the erection of large stores at their British Tube Works; Messrs. Loudon and Inglis, builders, have obtained permission to erect additional workshop and offices at their factory in Calder Street; the Coatbridge Co-operative Society were granted a lining to erect a range of stables in Jackson Street. Two petitions to convert buildings into skating rinks have also been presented.

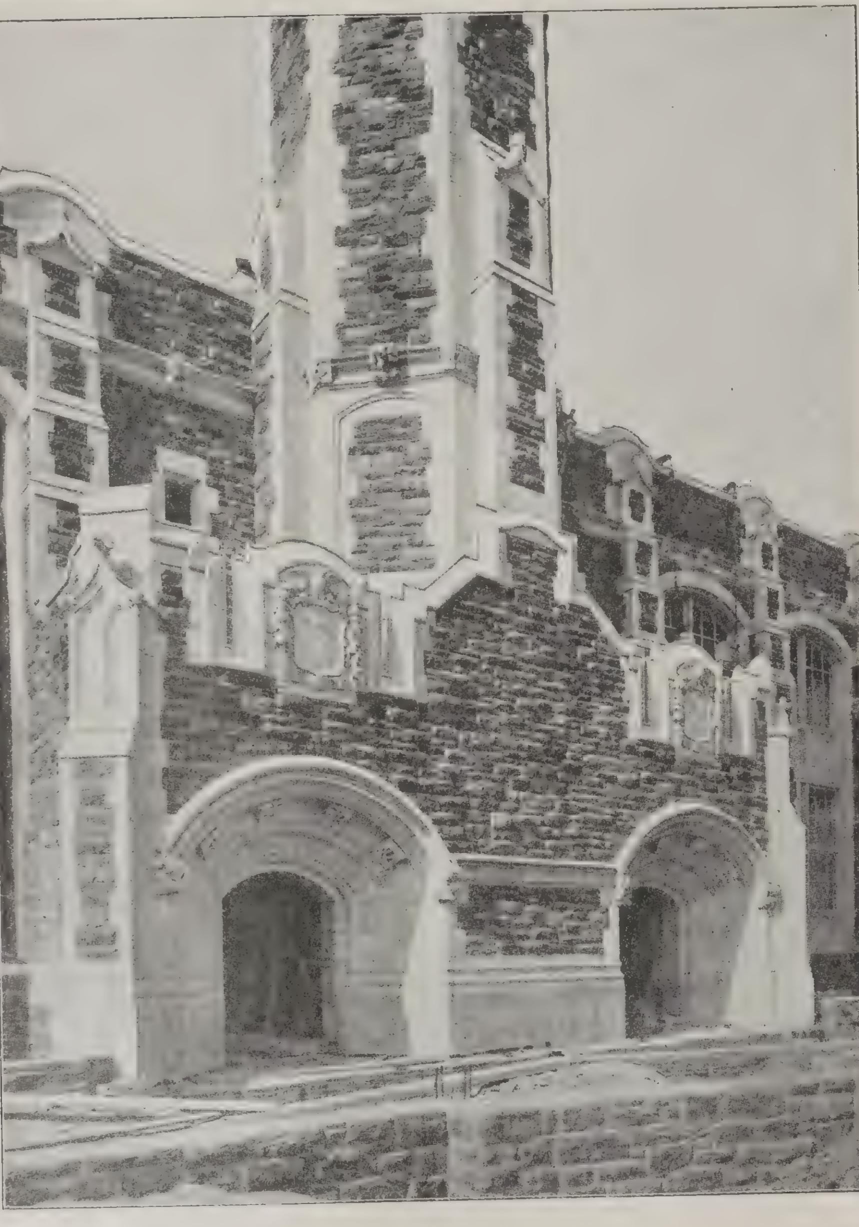
COWDENBEATH.—Premises have recently been acquired by the Cowdenbeath Co-operative Society at a cost of over £4,000, and it is now proposed to carry out extensive alterations at an estimated cost of £2,200. It is stated that the Post Office, which occupies a position upon this site, is to be abandoned, and a new one erected on a larger scale at the north end of the town.

CULROSS. — An extensive building scheme at Lower Valleyfield, Culross, is now under the consideration of the directors of the Fife Coal Company. Sinking operations have for some time past been in progress in connection with two pits which will be amongst the largest in Fife, and will give employment to between 1,500 and 2,000 men. The sinking of the pits is expected to be finished in about two years, and the building project of the Company will mean practically the establishment of a new village in the West of Fife.

FOLKESTONE.—The proposed enlargement of the public library, the cost of which Mr. Andrew Carnegie has promised conditionally to defray, will probably be started upon shortly. The result of a fête which was held to assist the extension fund, has been to make Sir Edward Sassoon, the Borough member, responsible for a contribution of about £700, Sir Edward having promised to supply the deficit.

FOSDYKE.—The Holland County Council has obtained the sanction of the Local Government Board to borrow £18,500 for the erection of a new swing bridge across the River Welland. The tender of Messrs Andrew Handyside and Co., of Derby, at £16,835, has been accepted.

LEICESTER.—A Local Government Board inquiry in respect to the application of the Council for a loan of £5,000 for the purpose of extending the Museum and Art Gallery, has been held. The Town Clerk, after narrating the causes that had prompted the application, pointed out that, in view of the urgent alterations which had become necessary, including the erection of a heating chamber, etc., at a cost of £576, the improvements to the western block facing the New Walk, which would cost £4,500, while the alterations to the hall, staircase, and first floor would involve £1,300, making £6,376 in all, the required loan was justified. Among the objections that have been raised against the alterations is the usual one of financial stress, and one of even more force, namely, that the site of the proposed extension is a public space and the property of the ratepayers. The cost of the building from its inception has been £18,000.



COLLEGE OF THE CITY OF NEW YORK. ENTRANCE, MECHANICAL ARTS BUILDING. GEORGE B. POST, ARCHITECT.

For description, see page 181.

MAIDSTONE.—The plans of the proposed isolation hospital having been approved by the Local Government Board, it has been recommended that tenders be invited for the erection of the building.

MATLOCK.—A scheme for the development of the Hall Leys Estate, a piece of centrally situated land about 20 acres in extent, is under the consideration of the Town Council. Suggestions having been made for the erection of a pump room, a concert hall, the provision of an ornamental lake, etc., the chairman of a recent meeting wisely advocated leaving the disposition of the scheme to the architects who would be invited to compete.

NORWICH.—For the erection of alterations and additions to the Norfolk and Norwich Hospital, the sum of £21,669 is required, and a like sum will also be necessary for endowment. The King has signified his intention to lay the foundation stone of the first of the series of new buildings on the occasion of his visit to Norwich on October 25th.

PEEBLES.—The recent destruction by fire of the administrative block of the Peeblesshire Fever Hospital, has been considered by the Joint Hospital Committee a suitable opportunity for the construction of a new building on a larger scale. The estimated cost of erecting and furnishing the building is £1,600.

RATHMINES.—The site upon which it has been proposed to erect a new public library having been found to be unsuitable, a committee has been appointed to institute inquiries into the question, with a view to obtaining one more desirable.

SOUTH SHIELDS.—The foundation stone of St. Oswin's Church, South Shields, is to be laid shortly. The site is in Stanhope Road, and the amount required for the first section of the buildings is £1,300.

STIRLING.—The safety of the old bridge which was built in the early part of the fifteenth century, is again menaced. Extensive restoration was carried out about twenty-eight years ago, but in spite of this the fabric again shows alarming signs of decay. The Provost and Town Council have taken up the matter, and will appeal to the Government to aid them in the preservation of this ancient monument.

TRURO.—It has been decided to build the tower of St. Paul's Church, Truro. The church was to a large extent remodelled from designs of the late J. D. Sedding. A set of tubular bells has already been promised for the new tower, which is to have figures at the corners instead of pinnacles. Mr. Edmund Sedding has been appointed architect for the tower.

WANDSWORTH.—An important addition, which is to be made to the Home for Aged Jews, is to provide accommodation for six married couples. The entire cost, both of erecting and furnishing the annexe, is being privately defrayed. The donor proposes to endow the new building, and this will involve a further donation of between £8,000 and £10,000.

WREXHAM.—An appeal for the erection of a memorial to Morgan Llwyd, the Welsh Puritan who has done so much to enrich Welsh literature, has been made.

Works in Progress and Completed.

ABBASSIO (EGYPT).—The contract for the erection of new barracks for the Egyptian Government, has been secured by Messrs. Henry Lovatt, of Wolverhampton. The barracks, which will take 3½ years to build, will be somewhat similar to those erected on Salisbury Plain. Concrete blocks are to be used in their construction.

BLACKPOOL.—The new police station which has been erected at Hawes Side to plans prepared by the Borough Surveyor, Mr. J. S. Brodie, is a two-storeyed building of red brick, with Accrington faced brick on the north and front elevations, with Nelson stone dressings. The buildings will probably cost £3,000. The general contractor for the work was Mr. James Eaves, of Blackpool.

BLYTH.—A bust of the late Lord Ridley has been unveiled. The present Viscount, who officiated at the ceremony, in the course of a speech observed, he believed landowners and town councillors should, in respect of town planning, look well into the future. He had had advice from his agent and also from his brother, an architect, and he thought the architectural possibilities of Blyth were great. He thought with the advice of architects they could make Blyth not only beautiful, but in some respects a model of town planning. The modeller of the bust, which is a striking likeness of the nobleman it represents, is Mr. George Skee.

CORK.—The many alterations and improvements which have been made at the Palace Theatre have been carried out by Messrs. John Delany and Co.

DENBEATH.—The Wemyss memorial hospital, whose cost has been entirely defrayed by Lady Eva Wemyss, was opened recently by that lady. The hospital is Scottish Baronial in style, and is equipped with every convenience. In the main building there are two large wards, with accommodation for six patients in each, and on pressure for double that number; an emergency ward for two or more patients; an operating theatre; and an administrative block, consisting of matron's, doctors' and nurses' rooms, etc. The laundry block is situated to the west of the main block, and a small chapel and mortuary occupy a corresponding position on the east side. The turret roof above and beyond the redstone pillared entrance to the hospital contains a large four-dial clock, with Westminster chimes. The hands of the clock are of novel design, representing a miner's pick and shovel. Mr. Todd was the architect.

FRANKSBRIDGE, RADNORSHIRE.—The new Baptist Church, which has been built here at an approximate cost of £950, provides accommodation for 250 worshippers.

KINGUSSIE.—The foundation stone of a new public hall in connection with the parish church has been laid. The cost of the building has been estimated at £900.

METHUEN.—The new auxiliary hall, the foundation stone of which was recently laid, will accommodate about 200 people, and is estimated to cost between £600 and £700. Mr. G. P. R. Young is the architect, and Mr. John Reay the builder.

SCOTSTOUN.—The new school which has just been opened at Victoria Drive, is three storeys in height, and is planned on the corridor system. On the ground floor is the infant department, attached to which is a large assembly hall, divided from the main corridor by a series of arches. On the first floor is the junior department, also with a large hall corresponding to that of the infant department. The upper floor is devoted to senior and higher grade departments. A gymnasium has also been provided, and will be fitted up with the new Swedish physical training apparatus. The architects are Messrs. Kerr and Watson, Johnstone, and the measurers Messrs. Shearer and Marr, Glasgow.

Notes and News.

Where Dwellings are Scarce.

Rochdale is just now enjoying a remarkable distinction. Almost alone among English towns, it shows a shortage of dwellings. Councillor Shawcross, moved by the touching tale of indefinitely postponed weddings, and other hardships of the homeseeker, has moved for a committee of enquiry.

* * *

Carpenter as Sculptor.

The memorial bust, in bronze, of the late Lord Ridley, which has been presented to Blyth by Lord Ridley, has been unveiled in the Ridley Park, Blyth. It was modelled by Mr. George Skee, a young carpenter of Blyth, whose clever work attracted the attention and interest of Lord Ridley, and it was subsequently executed in bronze by Mr. Alexander Parlanti, of Fulham.

* * *

A New Free Library for Folkestone.

Some months ago Mr. Andrew Carnegie promised to give £5,000 for the enlargement of the Folkestone Library on condition that the inhabitants raised, otherwise than by rates, the sum owing on the site proposed to be utilised. The Mayor issued an appeal, and a fête has been held to assist the fund. At the close the Mayor announced that a communication had been received from the borough member, Sir Edward Sassoon, stating that he would contribute whatever amount was required after the results of the fête were made known. About £700 is the sum the hon. member will be asked for.

* * *

A New London Hotel.

The Strand Palace Hotel, which will be opened on September 14th, occupies the site of Exeter Hall, famous as a centre of religious and philanthropic work, and as the home of the Young Men's Christian Association. The new hotel has only a comparatively small frontage to the Strand, where its main entrance is placed, but it extends behind the adjoining buildings to Exeter Street and Burleigh Street on either side, and also to Exeter Street in the rear. The hotel contains 470 bedrooms. On the ground floor there is a winter garden, adjoining the Strand entrance, and near it are a handsome drawing-room (with writing-room attached), and a large public dining-room. In the basement are a grill-room (also entered from the Strand) and billiard and smoking rooms.

* * *

Preservation of Ancient Monuments.

The Limerick County Council have had before them a report from the County Surveyor, Mr. John Horan, on the question of obtaining for preservation the possession by the Council of the ancient monuments in the county not already under the charge of the Board of Works. One tenant had refused to comply with the Council's request, and another was willing to meet the views of the Council if she received compensation. Mr. P. J. O'Sullivan, solicitor to the County Council, pointed out that under the Land Purchase Act of 1903 the Council may, with the consent of the Commissioners of Public Works, declare that any ancient monument or property shall not pass to the purchaser, and make an order investing such monument with the Commissioners. After some discussion, it was decided to refer the correspondence on the matter to the Board of Works.

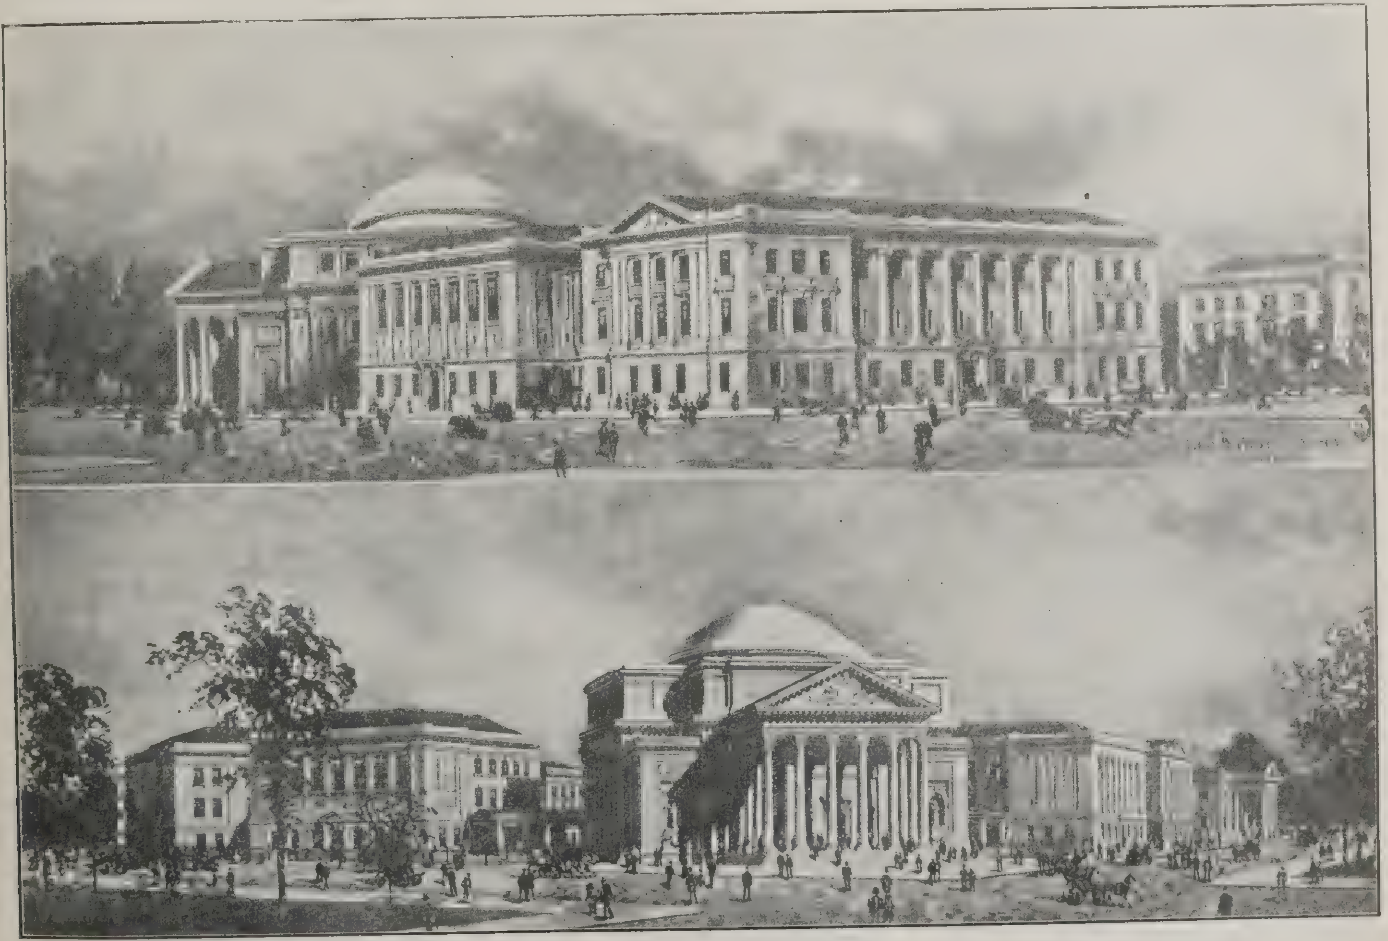
Local Tender v. Lowest Tender.

At the first meeting of the West Ham Board of Guardians after the summer recess, the Board discussed the tenders of 23 firms for the erection of receiving homes at Wanstead. The prices quoted ranged from £28,321 to £20,646. The latter price, which was the lowest, was quoted by H. J. Carter, of Grays, and it was proposed that the firm should have the contract. The Rev. A. G. Suttle moved as an amendment that the contract should be given to A. E. Symes, a local firm, asking £20,919. There was, he said, a tremendous number of unemployed in the district, and they would not gain the slightest benefit if the contract were given to an outside firm. The Chairman, opposing the amendment, begged the Board to adhere to the principle they had fought so hard for in the past. The local firm, however, got the contract, the votes being 15 to 11. The architect's estimate for the work was £20,000.

* * *

Sir Cuthbert Quilter's Model Cottages.

Mr. E. G. Pretyman, M.P., accompanied by Lady Beatrice Pretyman, Sir Cuthbert Quilter, and Mr. Geoffrey Drage were present at a formal inspection of some model cottages for aged labourers which Sir Cuthbert had erected on his Bawdsey estate. Mr. Pretyman said they appeared exactly to carry out the ideas embodied in his Bill, the object of which was to enable local authorities to provide cottages for labourers who were no longer able to occupy the cottages they had been paying for, partly in rent and partly by labour. It was a difficulty that affected labourers, farmers, and landowners, and it was desirable in settling it that the labourer should not be offered charity. Sir Cuthbert had provided cottages which could be let at a sum which would offer some return for the outlay. Having seen the cottages he should feel his hands strengthened in advocating the Bill that he had introduced. He would be able to refer to them as an example to be followed by county councils and others.



GEORGE WASHINGTON MEMORIAL BUILDINGS, WASHINGTON D C. GEORGE B. POST AND SONS, ARCHITECTS.

The design for the group of buildings for the George Washington University—part of the great monumental plan of the Capitol City of the United States—was selected in competition in 1905. For description see p. 183.

Improved Ordnance Survey Maps.

In a letter sent by the Board of Agriculture to County Councils and County Borough Councils indication is given of a proposal to improve the Ordnance Survey maps. A general revision of the Ordnance Survey maps on the scale of one inch to a mile and on smaller scales, occurs at intervals of fifteen years, and except in the case of railways, changes which take place after such a revision have not hitherto been shown on the maps until after the next general revision of the district. The councils have been informed that the Board propose in future to include in the maps any important additions, alterations, or corrections, such as the construction or demolition of main roads, canals, bridges, and other works affecting communications and the erection of large engineering works and other buildings of importance, without waiting for the next general revision. The Board ask that the councils should instruct any of their officers who may be cognisant of such changes to inform the Director-General of the Ordnance Survey, Southampton, when any change occurs of sufficient importance to be shown on a scale of one inch to a mile.

* * *

Shakespeare's Globe Memorial.

As mentioned in an editorial note in last week's issue, Sir H. Beerbohm Tree has consented to unveil in Park Street, Southwark, on October 8th, a mural memorial indicating the site of the Shakespeare Globe Playhouse, Bankside. Promoted by the Shakespeare Reading Society, of which Sir Herbert is President, as the result of a meeting at Lady Brassey's Park Lane residence in April, 1908, the memorial has been designed by Dr. William Martin, F.S.A., and executed by Professor Lantri, of the Royal School of Art, South Kensington. It shows in bronze relief Bankside in the time of Shakespeare, the Globe Playhouse forming the central feature, with the Thames and London Bridge in the background. A medallion bust of the poet appears in one corner, and an inscription runs: "Here stood the Globe Playhouse of Shakespeare, 1598-1613. Commemorated by the Shakespeare Reading Society of London, and by subscribers in the United Kingdom and India." The site of the old Playhouse is now covered by the brewery of Messrs. Barclay and Perkins, and so far as has been ascertained it is within 80 ft. to 100 ft. from Bank End. In 1613 the theatre was burned down, and was re-erected in the following year. The memorial measures 5 ft. 6 in. by 3 ft. 6 in., and it will be placed upon the wall facing Park Street.

* * *

A Shed for Dirigibles.

The War Department has placed with the Cleveland Bridge and Engineering Company (Limited), of Darlington, the contract for the construction of a building for the housing of dirigible ballons at Cove Common, South Farnborough. This building will be of steel construction, and have a length overall of 360ft., and an extreme width of 115ft. Its semi-circular roof will have a height at the centre of 75ft. Designs were invited from only four of the principal British structural engineering firms, and that of the Cleveland Bridge Company was preferred, although the amount of their tender was not the lowest. The shed has to be completed and handed over to the military authorities within 20 weeks from date.

* * *

The timber tithe barn of the Abbey of Peterborough, which was erected in 1306, was pulled down some years ago and the materials purchased by Mr. Fox, F.S.A., of London, who has now offered them to Peterborough Town Council with a view to their re-erection on another site. The building is 40ft. high, 80ft. long, and 32ft. wide. The council will give a reply in about a fortnight.

* * *

A French contemporary, in recording that a national museum at Cardiff is to be built, and that competitive designs are being invited, states that "the jury is composed of sir Aston Wibb, Mr. John James Burnet, and Mr. Edwin T. Hall." Burnet we know, and Hall we know, but who is Wibb?

* * *

"Most Wasted Site in Europe."

Mr. C. Ruding Bryan writes to a daily contemporary: "I was much struck by the boldness and truth in the statements of your correspondent concerning the unworthiness of the building in which our national collection of pictures is housed in Trafalgar Square. The position of the building—'the most wasted site in Europe'—is possibly the finest that London can now offer for such an institution; but that it has not been taken sufficient advantage of is apparent to all. Occupying the highest ground in the square, the National Gallery has the lowest skyline, and with its meaningless portico and detached columns scattered along the facade, it has justified the clamour for its demolition. This Corinthian order—a remnant of old Carlton House—naturally limited the architect when designing the Gallery, but it might still be preserved in a more truthful manner than was the fashion at that time. The galleries themselves—excluding their decoration—have much to commend them in point of size and proportion, but are unsymmetrically planned. In our latest museum at Kensington—a model of museum-planning, if not of art—we feel all the advantages of modern construction, which should, with similar success, be applied to our National Gallery of pictures. If, as a nation, we are less artistic than our neighbours, who suitably house the collections they form, we probably shall not rival the veteran magnificence of their galleries; but to copy with reasonable freedom is surely more virtuous than wilfully to ignore the benefits of example."

The substantial and picturesque new bridge over the River Wey, at Guildford, which was formally opened by the Mayor and Corporation on August 25th, was erected from the designs of Messrs. Clemence and Moon, architects, Guildford, Messrs. Henry Adams and Son, of 60, Queen Victoria Street, London, acting as consulting engineers.

Our Plate.

Further specimens of the admirable work that is being done in Liverpool University School of Architecture under Professor Reilly show a study of the Erechtheum, by Mr. W. Allan, and Mr. Ernest Gee's reproduction of features of the Lysicrates Monument. It is surprising that these studies can be invested with so much freshness and feeling; which qualities are even more pronounced in the water-colour originals from which our black-and-white version is reproduced.

In Parliament.

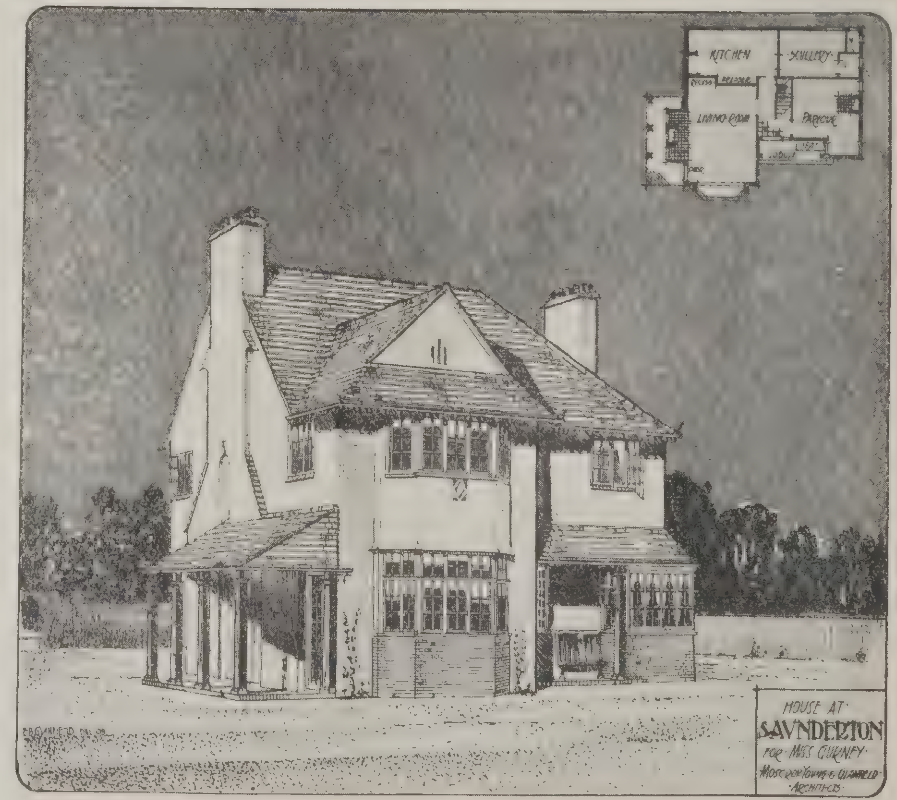
Places of Historic Interest.

Mr. Horniman asked the Chancellor of the Exchequer whether he had considered the request of the National Trust for Places of Historic Interest or Natural Beauty that land conveyed by gift or purchase, and dedicated to the use of the public and held by the National Trust or any such public body, should be exempt from stamp duty under Clause 53, Sub-section 1, of the Finance Bill. Mr. Lloyd George has replied that he has considered the communication sent to him by the National Trust, but he regretted that he did not see his way to accede to their request for the specific exemption from stamp duty under Clause 53 (1) of the Finance Bill. In exceptional cases of established hardship power already existed for granting relief.

* * *

Labour Exchange Appointments.

Mr. Summerbell asked the President of the Board of Trade, in regard to the appointments to be made shortly as to the Labour Exchanges to be set up, if he could state whether it was the intention of the Government to subject candidates to an examination test; and, if so, whether he could indicate the nature of such examination, especially in view of the fact that Labour Exchanges as proposed to be set up are new to this country. Mr. Churchill: The conditions of employment of the staff required are not yet definitely decided, and I am therefore un-



The pleasant homeliness of the elevation is confirmed in the comfort and convenience indicated by the plan, in which due importance is assigned to the living-room.

LIBRARY

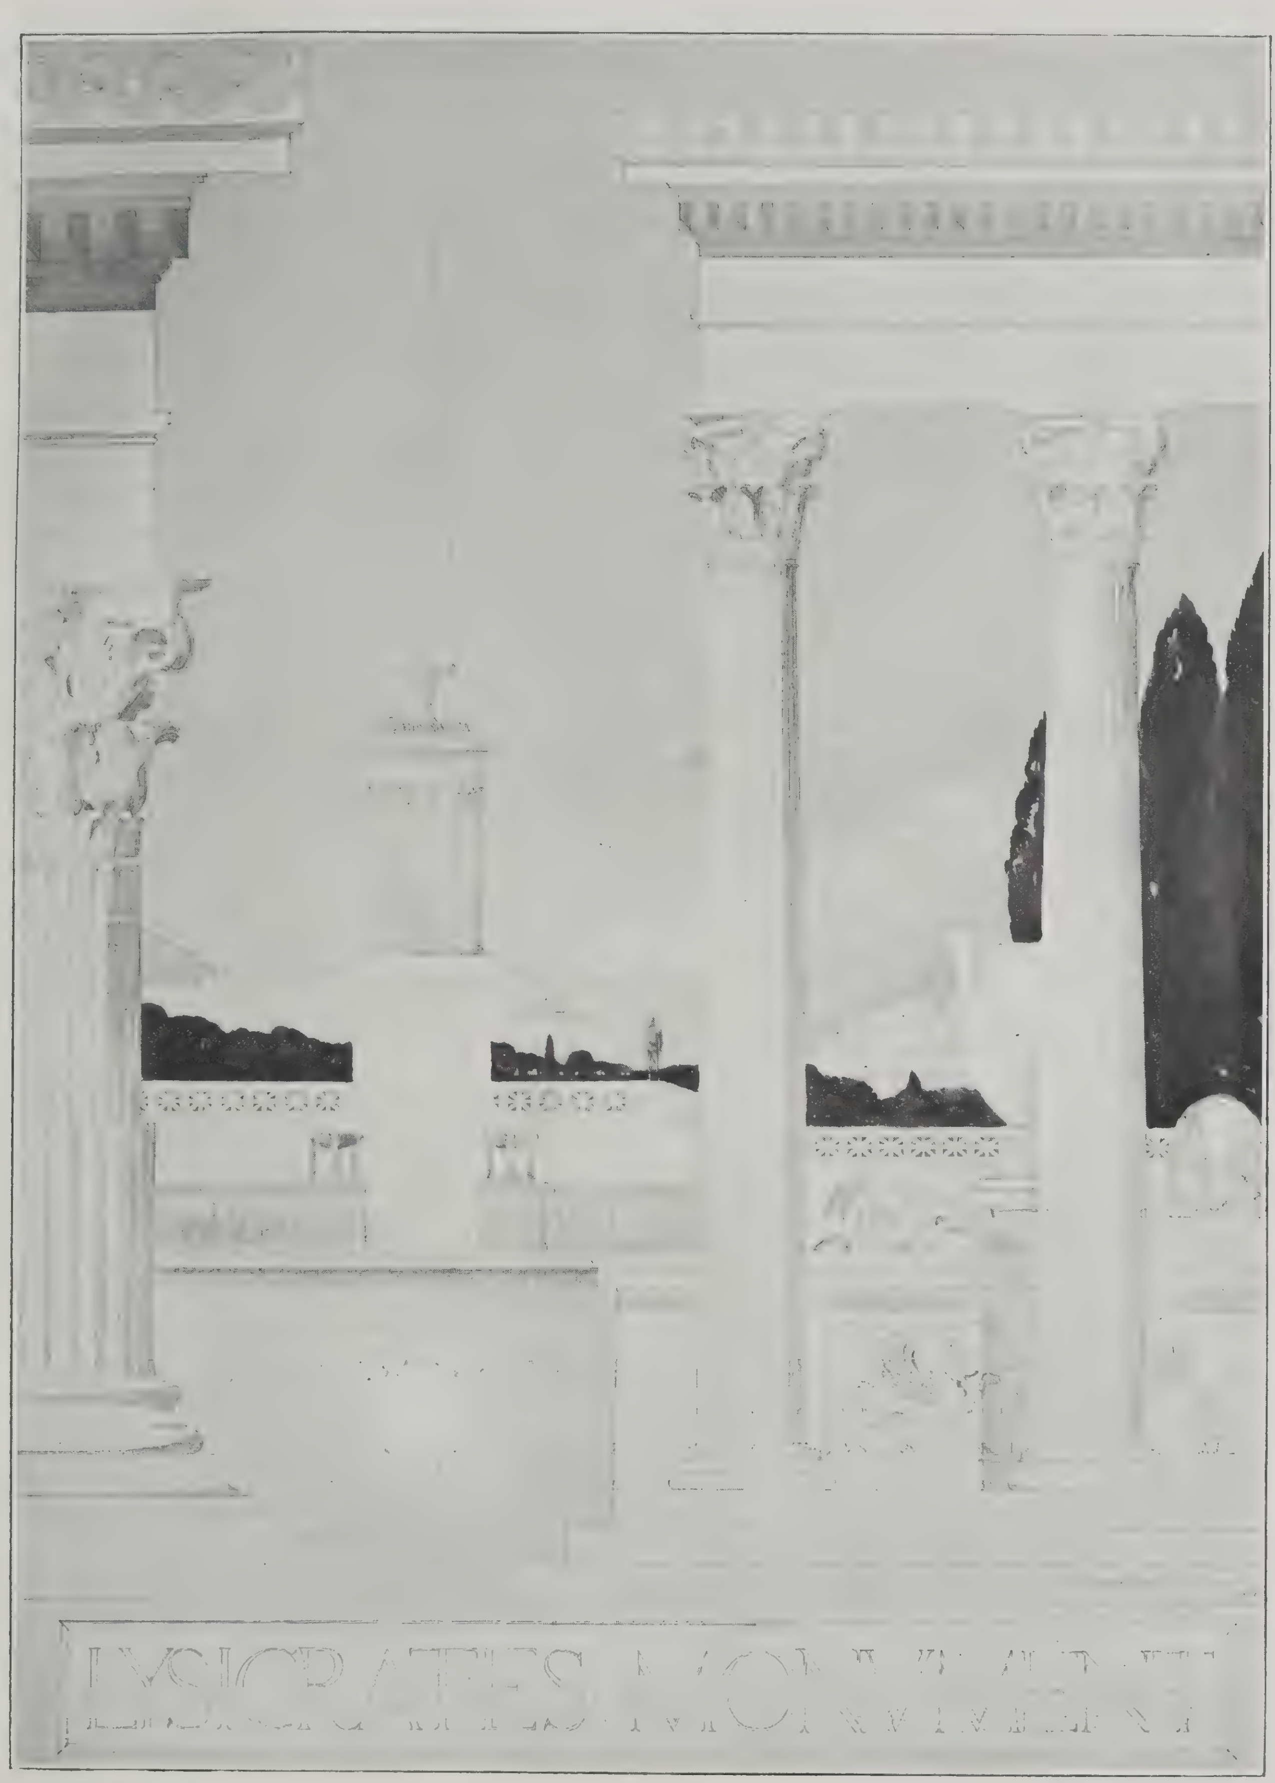
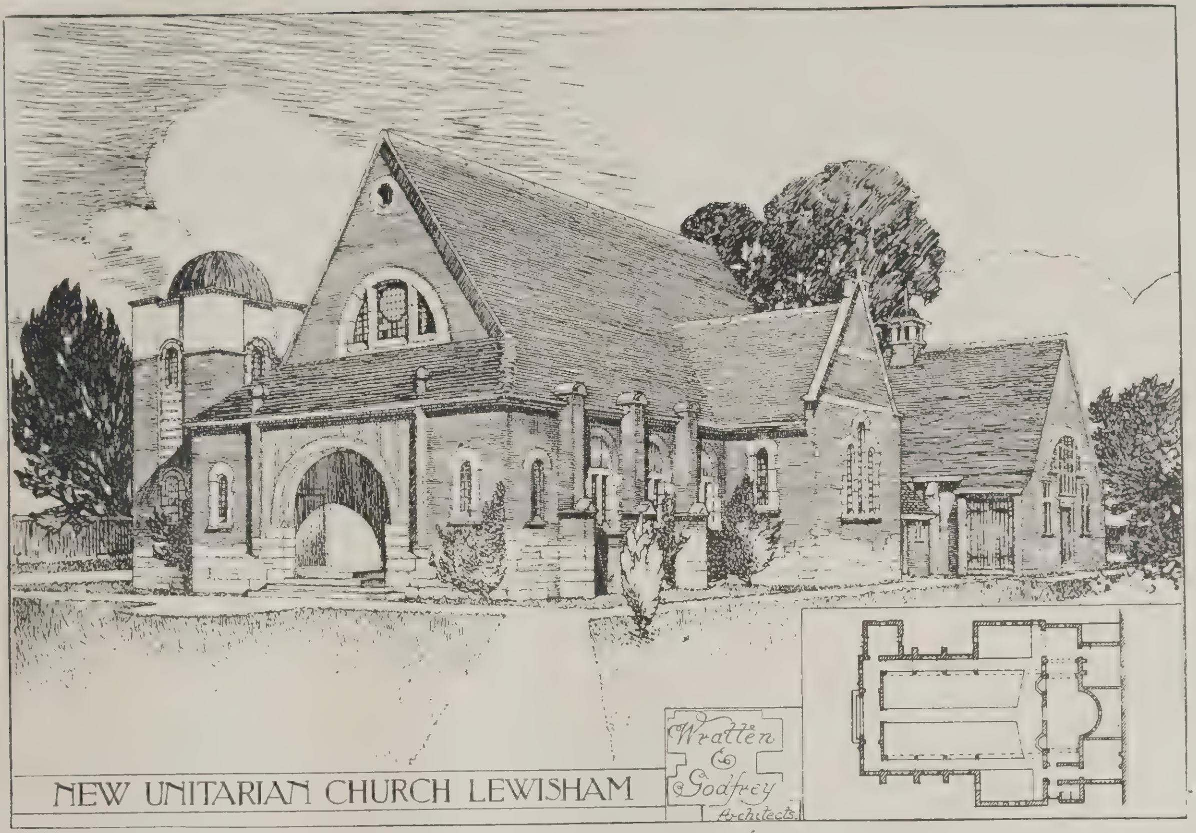
WATER-COLOUR STUDIES OF THE ORDERS, BY STUDENT



By ERNEST GEE.



This church is built on a base of Kentish Rag stone, with Dutch brick facings, and the roof is covered with hand-made tiles.

able at the present time to reply to the honourable member's question. I doubt, however, if the ordinary type of Civil Service examination would be altogether well adapted to test the qualifications of candidates for some of these appointments.

* * *

The Housing Question.

Mr. Keir Hardie asked the Prime Minister whether his attention has been drawn to the action of the proprietors of an estate in Merthyr, who had refused to sell or lease land to the Merthyr Borough Council for the erection of workmen's dwellings on the plea that the housing scheme of the council did not seem to be of an advantage to the estate; and whether it was intended by legislation or otherwise, to take from landowners the power to withhold land when required for housing or other public uses. Mr. Burns: The Prime Minister has asked me to reply to this question. The town council have sent me a copy of a letter which they have received from the solicitors to the owners of the estate referred to, and which is to the effect stated in the question. Local authorities are already empowered by Section 57 of the Housing of the Working Classes Act, 1890, to apply to the Local Government Board to enable them to purchase land compulsorily for the purpose of providing houses for the working classes; and I may add that under the Housing, Town Planning, etc., Bill now before Parliament the procedure in relation to this matter is proposed to be considerably simplified and improved.

Cinematograph Bill and Structural Alterations.

In the House of Commons, when the amended Cinematograph Bill came up for consideration, Mr. Cooper drew attention to the restrictive regulations, especially as they would apply to the entertainments given by religious associations on the Saturday evenings without their being able to make the necessary structural alterations in churches, chapels, schools and similar buildings. He moved an amendment in Clause 7 (Application of Act to special premises) providing that it should not be necessary to obtain a licence for premises "connected with a church or chapel or mission hall or public elementary school, and are not used more than one evening in any week from the first day of October to March 31st in the following year."

Mr. Lardner seconded the amendment, and pleaded for the consideration of such exhibitions in buildings connected with schools and chapels in remote districts of Ireland.

Mr. Gladstone said that he could not accept the amendment, pointing out that the object of the clause was to provide for occasional performances as distinct from regular performances. The amendment would interfere with the casual performance of the cinematograph, which the Government under this clause were trying to safeguard. He was certain that the county council would look after the safety of the public in all the smaller places of entertainment; but it was needful to provide against the danger from fire and against the dangers caused by panic. There was no intention to insist upon the enforcement of unreasonable regulations.

After some further discussion, in the course of which Mr. McVeigh (Donegal, E.) said the danger in these cinematograph entertainments did not come from the building, but from the incompetent operator, the amendment was withdrawn.

On the motion for the third reading of the Bill, Mr. Harmood-Banner (Liverpool, Everton) complained that for the purposes of the Bill the county councils were put above all the non-county boroughs. It might be all very well in the case of small agricultural towns, but in the case of the larger towns in Lancashire and Yorkshire, having their own regulations, it was a very serious matter. He hoped that in another place this would be looked into.

Mr. Gladstone said that if there was such a strong feeling in the quarter the hon. member opposite represented, it would have been better if his attention had been called to the matter when he introduced the Bill.

The Bill was read a third time.

With funds raised by public subscription, a drinking fountain of marble and white stone was erected at Lower Edmonton last week in commemoration of the King's Coronation. Why this precipitate haste?

Correspondence.

[*The Editor declines responsibility for the statements made by correspondents.*]

Builders' Locked-up Capital.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—The members of the building trade are deeply indebted to you for the very lucid and forcible article in last week's journal upon the disastrous effects of undue and protracted delay in the payment, more especially of the final balances, upon completed work. In many instances two, and sometimes three, years elapse before the last payment is made. During that time the builder's capital is not only locked up but wholly unremunerative. There is usually a penalty clause in contracts to enforce completion of the work contracted for within a certain date. It would be nothing more than equitable to have a penalty clause enforcing payment within a certain date, with the usual conditions of so much to be paid per day or per week, as in the case of non-completion at the specified time.

Looking at the subject from a builder's standpoint there is no reasonable excuse why his side of the bargain should not be as well guarded as the building owner's side. A large number of builders within my own knowledge have come to grief through their capital being locked-up and practically used for years by the persons who own the buildings.

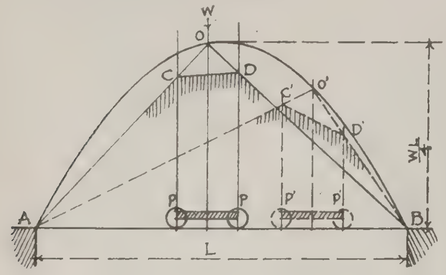
M.

Gantry Girders.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—Referring to the problem in your issue for August 11th, the bending moments for a rolling load on two wheels can be found very simply by the following graphical method, which I have never seen published:

Set up a parabola whose height is $\frac{WL}{4}$ (W being the total load $P+P$), then assuming the load to be carried on one wheel at the centre of gravity of the loads carried by the two wheels, the bending moment will follow the line of the parabola, as the single load passes over the girder. At any point O the actual bending moment for the two loads is found by joining OA and OB, cutting the centre lines of wheels at C and D. ACDB is the bending moment diagram.



This method applies whether the wheels carry equal or unequal loads.

Where only one wheel is on the girder, the other being on the abutment, the BM follows the line of a parabola, whose height is $\frac{PL}{4}$.

Edinburgh.

Law Case.

Effect of Trade Depression.

In the High Court of Justice (King's Bench Division), on August 31st, Messrs. W. Lawrance and J. J. Porter, trading as E. Lawrance and Sons, Builders and Contractors, who had carried on business at Wharf Road, City Road, N., attended for public examination, a receiving order having been made against them on May 21st last. Their statement of affairs showed gross liabilities amounting to £147,288 2s. 5d., of which £36,945 1s. 4d. was expected to rank, and assets estimated to produce £52,524. In answer to Mr. W. G. Williams, Assistant Official Receiver, Mr. Lawrance stated that the business which Mr. Porter and he had carried on was established in 1873 by his father, who died in September, 1898. Mr. Porter and the witness had become partners in 1882. His father's capital at the time of his death was £30,000, and a sum of £19,000 had since been paid out to the beneficiaries under his will; £9,000 had been carried to the credit of witness and his partner; and the remainder was allowed to be in the business, at 5 per cent. interest. Proper books of account had been kept, and they were balanced every year. Trading was successful until two or three years ago, when it fell off owing to slackness in the building trade, and they were unable to realise their properties in the present depressed state of the market. They had brought in a scheme under which the mortgagees would allow them time to realise the properties, and the scheme had been accepted by the creditors. If the properties were realised at the present moment in bankruptcy there would be a considerable loss. He had promises from all the second mortgagees and some of the first mortgagees that they would allow time for realisation. Mr. Porter stated that he agreed with the answers of his partner, and the examination was ordered to be concluded.

BERKSHIRE COUNTY COUNCIL NEW OFFICES, &c., READING.

ASSESSOR'S AWARDS.

At the moment of going to press, we have received intimation by telegraph that the following awards have been made in this competition:—First, Messrs. Warwick and Hall; 2nd, Mr. Shrewsbury; 3rd, Messrs. Hills and Anderson. Mr. Mervyn E. Macartney, F.R.I.B.A., was the assessor, and the premiums are £100, £75, and £50. Time will not admit of verification, but we suspect that "Hills and Anderson" should read "Wills and Anderson," "Hills" being presumably an error made in transmission.

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.
Oct. 11.	HULL TRAINING COLLEGE for Teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd, and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.
Nov. 30.	HERNE BAY PAVILION ON PIER. Herne Bay Urban District Council invite competitive drawings for a pavilion to be erected on the proposed extension of the pier at a total cost not exceeding £4,000, exclusive of architect's commission. Premiums of twenty-five guineas and ten guineas respectively will be awarded for such two designs as shall be judged of sufficient merit by the Council, and placed by them as first and second; the premium of twenty-five guineas to be afterwards merged into the usual commission payable to the architect, provided the work is carried out by such competitor. Plan of the site and copy of the conditions may be obtained on application to the undersigned on and after the 24th instant on payment of one guinea, which will be returned on receipt of a bona-fide design. Drawings to be deposited at the Clerk's Office, Town Hall, Herne Bay, not later than noon on the 30th November next.—Joseph Jubb, Clerk to the Council, Town Hall, Herne Bay.
No date.	NATIONAL MUSEUM OF WALES The Council desires to receive competitive designs for the erection of a new National Museum at Cardiff, Three premiums are offered. The Council have appointed Sir Aston Webb, R.A., Mr. John J. Burnet A.R.S.A., and Mr. Edwin T. Hall, F.R.I.B.A., as Assessors. Particulars and plans of the site will be supplied to competitors on payment of a fee of £2 2s., which will be returned on receipt of a design in accordance with the conditions, or if all papers are returned within 14 days. Inquiries to be addressed to Dr. Wm. Evans. Hoyle. Director of the Museums, City Hall, Cardiff.

REVISED AGREEMENT WITH THE PLASTERERS.

The revised agreement between the National Federation of Building Trade Employers, the National Association of Master Plasterers, and the National Association of Operative Plasterers, has now been signed on behalf of each of the parties. The genesis of the revision is clearly expounded in Mr. J. B. Johnson's report on the negotiations, which appears on page 156 of our issue for August 25th.

AMENDED GENERAL RULES, as agreed between the National Federation of Building Trade Employers of Great Britain and Ireland, the National Association of Master Plasterers, and the National Association of Operative Plasterers, September 1st, 1909.

No compulsion to become or cease to be Members.

1. The National Association of Operative Plasterers will not take any steps to compel men regularly employed as foremen or superintendents of Plasterers to become Members of the N.A.O.P., and the Employers will not take any steps to compel any men to cease their membership of, or prevent them joining the Operatives' Society.

Apprentices, number of and binding of.

2. No Employer shall engage any additional Apprentices to the Plastering Trade while the number of his Apprentices shall exceed one fourth of the number of Journeymen Plasterers then employed by him. All apprentices shall be legally bound, the Indentures to be open for inspection of the Operative Society within three months of the employment of the said Apprentices.

Rules enforced, no boycotting, etc.

3. No boycotting or blacklisting shall take place by the N.A.O.P. in future, where the firms adhere to the Rules mutually agreed upon, and should any firm be engaged to do any portion of Plastering Work, and do not pay the recognised rate of wages, it shall not be considered a violation of this Agreement, should the N.A.O.P. enter a protest. The Employers agree that such Rules shall be strictly enforced in all parts of their Contracts.

Demarcation Committees.

4. For the purpose of demarcation of work, Joint Committees shall be established in the different Districts, equally representative of the Employers and the Mechanics, whose representation shall be equally divided amongst the different branches of the trade in question. These Committees shall, as far and as soon as is possible, draw up schedules of the work which it is recognised belong to certain branches of the trade. To such Committees shall be immediately referred all points of dispute as to demarcation, and the decision of the majority in each case shall be accepted as binding on both sides. Should they fail, however, to decide, then the matter shall be referred for settlement to a similarly constituted Joint Committee, representative of the National Federation of Builders and the other Societies affected, whose decision shall be final, provided that the Employers' representatives are bona-fide Employers of Plasterers direct. Pending such reference to the Local Committees, no strike or lock-out shall take place, but the decision of the Employer shall be provisionally accepted as to who shall do the work, provided that preference shall be given to that branch of the trade which, in practice, has done the work before in that District, and provided that no preference be given on account of the payment of lower wages.

Disputes arising, how dealt with.—Local Joint Committees.—Joint Committee of Appeal.

5. In the event of any dispute arising, written notice thereof shall be sent by the party aggrieved to the Local Associations of the Master Builders and Master Plasterers or to the District Officials of the N.A.O.P. as the case may be, who shall inform the complainant party whether the party complained of is a member of any of the said Bodies, if so the matter shall be considered by a locally constituted Joint Committee of Employers of Plasterers and Members of the Operatives' Union, which shall meet within six clear working days of the date of the said notice, with a view to an amicable settlement; failing a local settlement, or, if no Local Joint Committee operating in the locality, reference shall immediately be made to a Standing Joint Committee of Appeal, consisting of members of the Employers' and Operatives' Central Bodies, which shall meet within 10 days of the receipt of notice of appeal to consider any case referred from the Local Joint Committee.

In the event of the Local Joint Committee failing to consider the dispute within the said six clear working days the party aggrieved may forthwith refer the case to the Standing Joint Committee of Appeal which shall then meet and consider the case as aforesaid.

Until the said Standing Joint Committee of Appeal has met and discussed the grievance, no strike or lock-out shall be sanctioned by any of the parties concerned in any dispute.

Expiry of Notices for Revised Working Rules.

In the event of any duly given notice or notices by either side, for a revision of local rules expiring without a settlement or withdrawal of notice or notices having taken place, the parties shall in the first instance refer the matter in dispute to the aforesaid Joint Committees, and pending a decision of the said Joint Committees, local or otherwise, no stoppage of work shall be allowed on any pretext whatever.

Joint Committees, Meetings and Elections.

The several hereinbefore mentioned Committees shall meet annually in May to elect Officers and Joint Secretaries for the ensuing year, and to transact such other business as may be necessary. The names of the representatives elected on the said Committees for each year commencing May 1st must be forwarded to the respective Joint Secretaries at least 14 days before that date.

Regulations, power to make.

The Standing Joint Committee of Appeal shall have power to make such regulations governing procedure under the Agreement as it may think advisable subject to confirmation by the parties hereto.

Defaulters.

6. With regard to the alleged refusal of members of the N.A.O.P. to work with workmen who may not belong to a Trade Union, it is understood the men the Operative Plasterers object to work with are defaulters, and other men, who have been shown to the Employers to have made themselves specially objectionable to the Union men, but no objection shall apply to any defaults which may have occurred prior to the date of the Agreement of 1899.

Local Standard Rate of Wages.

7. No Employer shall be called upon to pay more than the local standard rate of wages to men engaged in a town or district where the work is being executed, and where no established rate exists, that of the nearest town or district shall be adopted.

Construing Rules.

8. These Rules shall be construed together, and in the light of each other.

NOTE.—The words "local standard rate" and "established rate" in Rule 6 shall mean "the current rate that is being paid by established custom in the locality."

Signed,
JOSEPH CLARK,
Chairman of E.C.
WILLIAM HARNEY,
Member of E.C.

THOMAS LINDLEY,
President.
On behalf of the National Association of Master Plasterers.

REGULATIONS GOVERNING PROCEDURE under the Amended General Rules, agreed between the National Federation of Building Trade Employers, of Great Britain and Ireland, the National Association of Master Plasterers, and the National Association of Operative Plasterers, 1st September, 1909.

Joint Committees, duties of.

(a) Upon the Joint Committees established under the above named General Rules devolves the carrying out of the various clauses in the said Rules and of the following regulations.

The particular attention of the Joint Committees is requested in regard to Rule 2 of the General Rules, and it shall be their duty to see that as far as practicable all boys are indentured, and that boys passing from one Employer to another and having partly served their time, bring with them a statement from their former Employers duly endorsed to the effect that they have served a portion of their time satisfactorily.

Secretaries, appointment of.

(b) The Employers and Operatives on the several Joint Committees shall respectively appoint each a Secretary who shall summon the meetings, keep the minutes, and generally carry on the business of the Committees under the directions of the members at their officially summoned meetings.

Joint Committee, number of.—Joint Committee, convening of.—Vacancies, how filled.

(c) Each Joint Committee shall consist of not exceeding 10 Employers and 10 Operatives.

(d) All meetings of the several Joint Committees shall be convened by the Joint Secretaries.

(e) If any of the representatives on any of the Joint Committees die, resign, or otherwise cease to be qualified, a successor shall be appointed, and should any representative be unable to attend any meeting of the Committees, a duly appointed substitute may attend in his place.

Subjects, how brought forward.

(f) No subject shall be brought forward at any meeting of the Joint Committees except with the consent of a two-thirds majority of the representatives present, unless at least 6 days' notice thereof has been given to the Joint Secretaries.

Powers to discuss.

(g) Although the principal objects of the Joint Committees are the settlement of disputes as set forth in the Agreement of September 1st, 1909, it shall also be within their province to meet and discuss any question of trade interest at the request of any of the parties to this Agreement, providing that at least 10 days' notice in writing has been given to the Joint Secretaries of the Committee concerned setting forth the matter it is desired to discuss.

Area of Jurisdiction.

(h) The area of jurisdiction of any Joint Committee shall be the area in which the rules between the Masters' Association and the Operatives' Societies apply. In the event of an appeal being made to the Joint Committee of Appeal to consider a dispute and one side objecting on the ground that it is out of order, then the Chairman, Vice-Chairman, and two Secretaries of the Joint Committee concerned shall at once meet to consider the question and decide whether a meeting of the Committee shall be called. In those eligible localities where Joint Committees are not already formed, either section may take the initiative in forming or convening a meeting for the purpose of forming the Local Joint Committee.

Submission of Matter.

(i) The matter to be submitted to the Joint Committee should be definitely and specifically drawn up by the Secretary of the party lodging the complaint or appeal, so as to enable the Committee to consider and if possible give a decision upon the precise matters submitted to them. The case to be stated and the evidence taken should be scrupulously confined to the matter or matters definitely set forth in the appeal.

Power to Amend Appeal.

(j) The Joint Committees shall have power to amend the appeal to effectuate the real intention of the parties where the appeal has been erroneously or insufficiently drawn up. If a proposed alteration is a material one or will introduce new matter, there must be the consent of a majority of the Committee, the voting to be taken as hereinafter provided.

Date of Appeal.

(k) The date of appeal shall be taken to be the date when application was made by one of the contracting parties to the Joint Secretaries of the Joint Committee.

Proceedings at Appeal.

(l) The proceedings at an Appeal shall commence by the appellants making short statements of their case and calling witnesses in support of same. The other parties will be entitled to make a short statement of their case, call witnesses, and produce evidence. The appellants shall have a right to reply. All witnesses to be subject to cross-examination.

Witnesses.

(m) Witnesses shall only give evidence on matters which are within their personal knowledge, and hearsay evidence shall not be admitted. In case of illness or any other cause which makes it absolutely impossible for a witness to be present, the written statement of such witness shall be admitted, but must be signed and attested by two witnesses.

Evidence.

(n) All evidence and information in relation to the matter under consideration communicated by one of the parties or their witnesses or agents shall be in the presence of the other parties. All the evidence to be submitted by both parties shall be heard before the case is closed by the Joint Committee.

Case Closed.

(o) When the case has been formally closed the parties and witnesses shall retire, and no further evidence shall be heard or information communicated.

Members of Committee Representing Parties.

(p) If a member of the Joint Committee has represented one of the parties as a witness during the hearing, he shall retire when the case has been closed, and not take any part in the deliberation of the Committee while considering the evidence and arriving at their decision.

Minutes.

(q) Draft Minutes of all Meetings shall be mutually approved by the Joint Secretaries within a short period (say five days) and the record in both Minute Books should be identical therewith.

Regulations, how determined.

(r) These regulations are for the purpose of effectually carrying out the Agreement already agreed upon for the settlement of all disputes which may arise between the parties thereto, and any determination of the said Agreement either by effluxion of time or notice given by any of the parties thereto, will apply with equal force to these regulations.

Quorum.

(s) A majority of the representatives on each side shall constitute a quorum at any meeting of the Joint Committees. The voting power of Employers and Operatives to be equal in all cases.

Decisions and Voting.

(t) The decision of any of the Committees to be binding must be carried by a majority of votes of those present, and in the event of the attendance on each side being unequal, a unanimous vote of the numerically weaker party shall be considered equal in number to the unanimous vote of the stronger side, and the result shall be a tie; but should there be cross voting the decision shall be given in favour of the side securing a majority of such cross votes. The Chairman shall have one vote only as a member of the Committee, and shall not be entitled to give a casting vote.

Arbitration.

(u) Though in all ordinary cases the procedure shall follow the regulations above written, yet for the purpose of more quickly arriving at an agreement on matters in dispute, it shall be competent for any of the several Joint Committees by mutual and unanimous consent of the two parties to call in an arbitrator or arbitrators with power to settle the dispute, and where this is done the decision of such arbitrator or arbitrators shall be final and binding. In the event of an arbitrator or arbitrators being called in by any of the Joint Committees, the costs, if any, shall be borne in equal shares by the Employers and Operatives unless left to the discretion of the arbitrator or arbitrators by mutual consent of the Joint Committee.

Regulations, how altered.

(v) Any party desiring an alteration of these regulations shall give six months' notice in writing to the Joint Secretaries of the Joint Committee of Appeal, prior to the Annual Meeting thereof, and such notice shall at once be communicated to all the parties to this agreement, and the Joint Committee of Appeal shall have power to alter these regulations by a majority of votes of those present at the Annual Meeting thereof.

STANDING ORDERS

Governing Procedure in Debate.

1. All motions or amendments shall be reduced to writing by the proposer or seconder immediately on their being seconded.

2. Whenever an amendment is made on an original proposition, no further amendment shall be taken into consideration until the first has been disposed of.

3. If the first amendment be carried, it becomes itself an original question, whereupon a further amendment may be moved.

4. If the first amendment be negatived, then a second may be moved upon the original question under consideration; but only one amendment shall be submitted to the meeting at one time.

5. The mover of any original resolution, or of an amendment carried, shall have a right to reply before the question is put from the chair; but no other member shall be allowed to speak more than once on the same question, unless fresh evidence is introduced or the attention of the Chair be called to a point of order.

Signed,
ERNEST J. BROWN,
President.
A. G. WHITE, Secretary.
On behalf of the National Federation of Building Trades Employers of Great Britain and Ireland.
THOMAS LINDLEY,
President,
On behalf of the National Association of Master Plasterers.

Trade and Craft.

A New Domestic Boiler.

The National Radiator Company, Ltd., 439 and 441, Oxford Street, W. (works at Hull), send particulars of their new "Ideal" domestic boiler for hot water supply for domestic and other purposes, and for low pressure hot water heating. The "Ideal" boilers are constructed of cast iron, not of ordinary grades, but of a special mixture determined after more than thirty years' experience in the manufacture of boilers. As the efficiency and durability of cast-iron boilers are largely due to the quality of material used in their construction, care is taken to have every pound of iron not only carefully selected, but the castings subjected to daily tests and analyses in the laboratory. These boilers are, therefore, practically indestructible. Three 4-in. openings at the top permit the easy removal of the incrustation, without disturbance of the existing piping and smoke pipe connections. All the fire surfaces are backed with water, and therefore cannot burn out. The waterway is nowhere less than 3½ins. wide, and extends to the floor line; this not only facilitates cleaning, but provides large water storage capacity in the boiler itself. Two 4-in. openings are provided at the bottom for the removal of the sediment. These openings, as well as those at the top of the boiler, can be fitted with brass tapered plugs, making a tight joint without packing, and easily removed at any time for cleaning. The return tapping is 4¾ins. from the floor, so that even when a considerable quantity of sediment has collected at the bottom of the waterway, this will not be disturbed by the ebullition of the water within the boiler itself, and consequently a clean supply in the system will always be available. In private residences a self-contained boiler for the supply of hot water has a distinct advantage in convenience over the kitchen range boiler, and also ensures the maximum economy, as there is usually little need for hot water when the greatest heat is required, viz., when cooking is in progress, whilst the supply of hot water is generally found inadequate when it is most in demand. The "Ideal" domestic boiler is equally suitable for small installations of low pressure hot-water heating in conjunction with "Ideal" radiators or for the combined system of low pressure heating and hot water supply.

"A Century and a Half of Commercial Enterprise."

The Carron Company have just added to their series of neatly and even artistically produced booklets an interesting souvenir of the firm's completion of a century and a half of existence. The Carron Company was founded in 1759, and was virtually the pioneer of the iron industry in Scotland, and has enjoyed an unbroken business career throughout that long period. It was a Roebuck of Sheffield to whom was largely if not entirely due the inception of the firm—Dr. John Roebuck, an eminent mineralogist, who discovered some important improvements in the production of iron. It was he who, while in partnership with Samuel Garbett, as chemical manufacturers at Prestonpans, near Edinburgh, discerned the possibilities of exploiting the great mineral wealth then lying unheeded between the Forth and the Clyde. The company formed at his suggestion consisted of himself, Ebenezer Roebuck, Thomas Roebuck, William Cadell, sen., William Cadell, jun., Benjamin Roebuck, and Samuel Garbett, the junior Cadell being the first manager. The erection of the foundry works was begun towards the close of 1759, and the work of ironmaking at Carron was begun on January 1st, 1760, Dr. Roebuck piercing the furnace breast for the first flow of metal. It happened that Mr. Garbett was an enthusiast in military matters, and he urged the desirability of manufacturing cannon and cannon-balls. Hence the small naval gun of a distinctive type received its name of "Carronade." These guns played a most important part in the French wars at the end of the eighteenth and beginning of the nineteenth centuries, and became world-famous. The firm eventually abandoned for a long period the manufacture of firearms, but, a few years ago, made a large quantity of shells for the British Government. But, from the very outset of its career the firm has been identified with the manufacture of the implements of peace, and soon established a reputation for the excellence of its firegrates and other domestic appliances, as well as for agricultural implements. The company was incorporated by royal charter in 1773, when Dr. Roebuck severed his connection with the firm. In 1787, Robert Burns visited the works, but was refused admittance, whereupon he scratched a lampoon on the window of a neighbouring inn, to the effect that when he knocked on the gates of hell (a comparable place, *bien intendu*) he might be, in this similar application, equally unsuccessful. His poem, and a neatly turned epigram in reply to it, enliven the pages of this well-written account of the Carron Works. The first set of complete castings for the steam engine, the invention of James Watt, were cast here, and were erected at the house of Dr. Roebuck, who included also among his personal friends John Smeaton, of Eddystone Lighthouse fame, who designed and superintended several works for the company. The engines for the first steamship built in the United Kingdom were made at Carron Works. It is in the light foundry, which is the largest of its kind in Scotland, where the firm's cooking apparatus, ranges, firegrates, baths, and lavatories, etc., are made; and a subdivision of this foundry is expressly devoted to the manufacture of rainwater and soil pipes, gutters, window-frames, skylights, etc. The company is so fortunate as to possess a great number of carvings designed in the eighteenth century by those fine artists William and Henry Haworth, who were pupils at the Royal Academy during the presidency of Sir Joshua Reynolds, and these are not only introduced with artistic effect in many of the firm's productions, but doubtless have set a high standard for the emulation of later designers. The souvenir, which is daintily illustrated, is, in short, replete with an astonishing variety of interest.

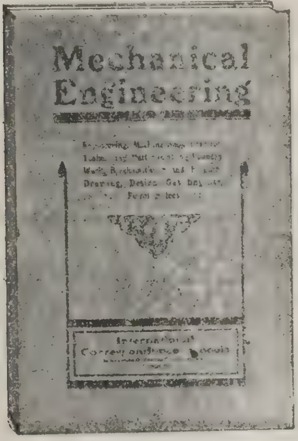
Caxton House, Westminster, S.W.

Descriptive Leaflet sent post free upon Application.

Five Years Ago these Two Men Started Level

—one is still at his bench, toiling hard and long for a slender pittance—the other now occupies a high-grade position in his profession, enjoying high pay, congenial work, influence and power. What is the reason of the present difference in their fortunes? It is not that the successful man has more brains than his "stand-still" colleague of five years ago—**but he does know better how to use them.** In a word, he has **trained** his brains on practical remunerative lines, while the man still at the bench has not.

This instance is just typical of thousands we could cite in which men have devoted a few months to serious home study with the International Correspondence Schools, and, as a direct consequence, have secured a future of success and happiness, while their less ambitious colleagues have condemned themselves to a monotonous continuance of the old round of drudgery.



Free books on subjects below.

What about Yourself Five Years from now?

You must be ambitious or you would not have read thus far. Determine then to realise your ambition—to rise out of the rut—by enrolling right away for a course of specialised training with the International Correspondence Schools. Spare time home study only is required. You make the fullest use of your leisure, wasting no time travelling to and from classes. You make every hour you give to study count in your career, for the I.C.S. course arranged for you will have the one and only aim of preparing you for the high grade position to which you aspire.

The evidence of the thousands of students who have benefited by our training during the past 17 years is conclusive on this point. This is how one of them puts it—

House Inspection. Mr. T. C. Horsfall, whose utterances on housing questions always command the utmost respect, for he speaks with authority and not as the Scribes, thinks that Clause 30 of the Housing and Town Planning Bill ought to have been retained—the clause that provided for the systematic inspection of small dwellings. He points out that such a system of inspection has operated so successfully in many parts of Prussia as to induce the Prussian Government to insert clauses in their last Housing Bill to make inspection compulsory in all parts of the Kingdom. Mr. Horsfall says that the faults and defects found wherever there is inspection may be divided into three principal classes: serious faults in the structure or position of dwellings; minor defects, such as defective roofs, walls—easily removable; insufficiency of light and air, due to the neglect of the owners or their agents; and faults, such as dirtiness, dampness, lack of air, due to the neglect of tenants. "Now," he argues, "it is a well-ascertained fact that these faults in dwellings have results which have to be paid for by the payers of rates and taxes. The faults are known to be causing a large amount of tuberculosis and other diseases, the sufferers from which have to be maintained at the public expense, and they are causing in other ways a great deal of poverty, inefficiency, and crime, which cause us all enormous expense. If systematic inspection of all small dwellings can lead to the removal of the faults, it will certainly be cheaper in the long run for us all to have it than to refuse to bear the cost of discovering what is wrong in all small dwellings and of getting all that can be put right, put right as soon as possible. German experience shows that systematic inspection is causing the removal of a very large proportion of the causes of disease, and that its cost is not high." Mr. Horsfall's logic is irrefutable, but he leaves out of the account the most vital element. It is not a question of cost, as Mr. Horsfall seems to think. Mr. Burns, it is true, made much of that aspect of the case; but we suspect that he had at the back of his head a shrewd knowledge of the real difficulty of the situation, but did not like to mention it because its expression would have sounded rather sentimental. It is merely this—that the German sentiment—more especially the Prussian variety—is vastly different from our own. The Prussians are accustomed by traditional usage to being inspected from top to toe, inside and out, and with them any sort of poor creature in a uniform is a demigod, whose frown it is sacrilege to brave. On the other hand, the free and bold English spirit tolerates any form of inspection very badly. Anything in the nature of a domiciliary visit is heartily detested and bitterly resented. Hence, Clause 30, as we ventured to observe before it came up for judgment, was foredoomed to failure. In our view there was nothing the matter with it except that it was unpopular, and there was an end to it.

The Combined Drainage Conundrum. The numerous questions addressed to us with reference to combined drainage, show that the subject is in sore and urgent need of simplification. "When is a drain not a drain?" is a sort of conundrum to which the plain man is apt to answer in despair, "I give it up." The element of despair is observable in a report to hand of a debate on the subject by the Dublin Corporation. Having regard to the great number of combined drains in the city "injurious to health," the Public Health Committee were asked to report as to the Corporation's position under the existing law, and they have been told that "the liability involved might amount to as much as £100,000 in a few years." They think that this estimate is exaggerated, but their report was thought to reach the opposite extreme of excessive optimism, and was referred back. It has always seemed to us that the worries and responsibilities thrown upon private owners, architects, and builders, to say nothing of municipal officials, by the indeterminate state of the law as to drainage, are too heavy for them to bear. The measure of relief that has been accorded them within recent years has been quite insufficient. We are very well aware of the difficulties that stand in the way of drastic reform; the chief being that indicated in the Dublin report. The cost to the community would be enormous. But apparently it would be very well worth while. To determine at once and for ever the vexed question of drain or sewer, and to extinguish at a stroke the anomalies arising from joint or separate ownership, is not impossible. It is only impracticable because of the heavy burdens already borne by the long-suffering ratepayer, who would kick vigorously, as he is doing at Dublin, if asked to take over the responsibility for the innumerable drains that are still repairable by private owners. If, it is sometimes argued, the private owner were not liable to repair the drains he constructs, he would construct them without the least regard for their durability, because the expense of keeping them in repair would fall upon the community. But the incidence of the burden would be an additional reason for more adequate official supervision of the work. It is the old drains that cause nearly all the bother. If all the antiquated and inefficient systems still in operation in various parts of the Kingdom were brought up even to the minimum standard of efficiency exacted by modern sanitary science, the expenditure on the work would probably amount to more millions than the estimated cost of eight new Dreadnoughts. Yet it is work that ought to be done if the death-rate from zymotic diseases is to be still further diminished, and if the constantly recurring and harassing questions of responsibility are to be set at rest.

The Picturesque and the Prim. The time is coming, and now is, when the tour of any latter-day Dr. Syntax in search of the picturesque must be barren and fruitless; unless the ideas of picturesqueness happen to change with the times. There are many by whom this quality never will be missed, or will be missed with a sense of satisfaction rather than of sorrow. The hard-headed economist distrusts, if he does not detest it. Picturesqueness is apt to be inconvenient and insanitary. The thatch of the lovely country cottage is loaded with loathsome disease germs; its creeper-covered walls are damp and noisome, its windlassed well is the breeding-place of zymotic diseases, and so forth. Recurring instances of the truth of this formidable indictment have led to the evolution of a cottage that appeals to the mind as well as to the eye, because it is known to be wholesome and commodious, as well as seen to be comely of form. This is surely an instance of the revision of one's ideas upon what is picturesque. It has set up a more robust standard of judgment, in which healthy sentiment supersedes sickly sentimentality. Even so when, as legislation threatens, all the roads are levelled and widened and straightened, and when all the winding lanes and picturesque corners have disappeared in the process, we may perhaps come to the point of rejoicing in a "superior consideration." There will be fewer motor accidents, even if Mr. Lloyd George fails to materialise his heroic scheme of running straight and level motor roads through our prettiest bits of landscape at the cost (estimated by an expert figure-fiend) of £8,000 a mile; for the more conservative of the town-planners will be pretty hard put to it to prevent the more prosaic from effecting the elimination of picturesque but awkward corners, and the reduction of everything to a Dutch dead-level of flatness, with glazed-tile dolls' houses to match. The utilitarian faddists will not have it that convenience and cleanliness can be bought too dear, or can be pushed to an absurd extreme, and their zeal will have to be curbed if the country is to retain its old-world charm. The avoidance of an excess of Dutch primness will be one of the principal problems of practical town planning; and it is certainly made more difficult by certain provisions of the Development Bill, which has now been sent to Grand Committee. Well might Lord Rosebery say that "the destinies of England are in the melting pot."

Shields and Chivalry. Whatever may be the shortcomings of the typical rural district councillor, he is seldom or never deficient in dogged pluck. A mild example of this eminently British quality is thus laconically recorded in a South Shields newspaper report of a recent meeting of the R.D.C.: "Some discussion ensued about the right of Mr. Johnson to board up a back lane in the rear of his premises. Mr. Laidler said they would have to instruct their surveyor to knock it down. Mr. Johnson declared that it would not be knocked down if he was about. It was decided to adjourn the matter for two months." That was a debate in the manner beloved of Sir Conan Doyle's chivalrous old Sir Nigel: he loved to "debate with sword or lance." Mr. Johnson, like his illustrious namesake, the Great Cham of Literature, and like the even more eminent and not less formidable "rare Ben," is evidently of sturdy and indomitable character—"a tall man of his hands." It was therefore prudent of the Council not to thwart him in his challenging mood. In the course of two months the general temperature is likely to become much cooler; or the Equinoctial gales may providentially spare the surveyor the formidable task of bearding the intrepid Mr. Johnson in his own barricaded back-yard. But, on the other hand, this prolonged armistice may give the stalwart defender abundant opportunities for laying in provisions and armaments, and strengthening his fortifications, in which case the surveyor might be well advised to go into strict training for the Homeric encounter, and to take a few lessons in the gentle art of ju-jitsu. Then, by doughty deeds, he may secure increased respect for his prowess in levelling, and the fact that Mr. Johnson is "about" shall not make him afraid.

See Naples and—Dirt. The building trade in Naples at the present moment may be considered brisk. A few large buildings are being erected at the westward end of the town, and in addition several of the largest blocks nearer the centre of the city are being modernised. This treatment has extended to the outward appearance of the buildings. The coloured stucco work has been removed and the brickwork cased in with stone. The design of window and door openings is more in accordance with modern ideas, perhaps not a great improvement, for in conjunction with the latest treatment of window and shop fittings much of the local character is lost. In one respect the town still maintains its pre-eminence; it still remains one of the dirtiest and noisiest places that can be conceived. Every street corner forms a local dustbin, with an overflow into the road, or pavement where it exists. The Neapolitans, if they could only be persuaded to see the value of such a course, would do well to import a strong English town council and municipal officials. Five years of resolute management would be necessary to give an appearance of cleanliness, but it would take generations to make it permanent.

Memorials of Greater London. The issue of another important publication by the Committee for the Survey of the Memorials of Greater London affords a legitimate opportunity for again drawing attention to the excellent work that is being quietly and unobtrusively accomplished by this exceedingly useful organisation. The object of the Committee could hardly be better or more succinctly expressed than it is in the words of a circular that has been sent to us: "The object of the Commitee has been to take up certain areas in London, and in them to register and record with drawings, photographs, and other records, whatever may be deemed to be of historic or aesthetic interest. The work is not confined to buildings only; any object of local life or custom that may have a definite external embodiment, or any interesting piece of handicraft, even if it be but a signboard or a wrought-iron gate, comes within the Committee's survey. The aim is to draw attention to these things. If they are in private hands, to get the owner's consent towards their registration; if under the guardianship of any representative public or semi-public authority, to encourage their maintenance, for public purposes, as national trusts." The modesty of tone observable in this statement is maintained in the Committee's operations, and is as a refreshment to the soul that has been too often vexed to wonderment whether other and much more aggressive bodies, professing similar aims, do not care rather for the joy of combat than for the object of the contention. The Committee can be very firm on occasion, but it has never developed what, for want of a better word, may be called the cantankerousness that excites opposition rather than effects conversion. It does its spiriting very gently, and in this way its energetic and accomplished band of active workers have achieved tangible and splendid results. It has compiled a very large and beautiful collection of drawings, photographs, sketches, measured work, etc., to the number of about 2,500 items. Eleven monographs on work deserving special attention have been published, the latest of which, "The Survey of Chelsea," is perhaps the most interesting of the very fascinating series. We hope to have an early opportunity of noticing it at greater length. Readers of "The Architectural Review," in which, month by month, the Committee's current work is illustrated, have enjoyed a foretaste of the æsthetic interest of this volume, and will be glad to have the records in collected form. The price of the volume is 25s., but membership entitles the subscriber to all the Committee's publications for the year—a rich return for his guinea. The secretary is Mr. Percy Lovell, B.A., A.R.I.B.A., 23, Old Queen Street, Westminster, and on the lists of honorary and active members we notice the names of several well-known architects. We should like to see more; for it is perfectly obvious that the interest of the Committee is largely architectural; otherwise this note would not have been written.

THE CITY OF NOBLE TOWERS.

By A. K. Carr.

A City of Towers, rather than a "City of Spires"—a City of Churches even more than a City of Colleges: a city of gardens, of venerable buildings, stately avenues, and velvet lawns; of grey stone walls festooned with creepers — a symphony in grey and green. Such is the general impression of Oxford, seen on a summer day in vacation. Antiquity is its dominant note: tradition clings to it as its lovely creepers cling to its ancient walls. A classic calm pervades the atmosphere—a serene dignity, far removed from twentieth century unrest. Here is a city where the spirit of commercialism is made to play a subordinate part: where the material is subjugated to the ideal. Oxford is a City of Ideals; and many of its ideals are embodied and expressed in stone. In the presence of its hoary buildings, instinct with the spirit of the dead centuries, the trivialities and the sordidness of modern everyday life fall away, and leave us face to face with the Spirit of the Past. Tradition lays its hand upon us, and the present fades into insignificance. In the City of Ideals we become idealists.

To the lover of architecture, especially of ecclesiastical architecture, the attractions of Oxford are, of course, inexhaustible. It represents the styles and methods of nearly a thousand years, from the Saxon tower of St. Michael-at-the-North-Gate to the modern Church of St. Barnabas—the only church in Oxford in the Italian style, rearing its campanile beside a railway line—in "Jericho!"

The antiquity of St. Michael's tower makes it, for some of us, the most fascinating of all Oxford's buildings. Supposed to have been built by Robert D'Oily in the reign of William the Conqueror, but probably only restored by him, and therefore of much earlier date, it is uncompromisingly severe in its simplicity. It was designed more for utility than for ornament, having been erected as a fortress tower on the north wall of the city, though now, owing to the great expansion of Oxford towards the north, it occupies a position south of the centre of the town. The church attached to it is evidently of much later date than the tower, which is by far the oldest building in Oxford, and one of the oldest in the country. Its fortress character is instantly apparent—a sturdy pillar of rough grey stone, with quaint little arrow slits, situate high up in the tower, while the lower part of its grim face is unrelieved by door or window. The absence of buttresses is a notable feature, testifying to the antiquity of the work. The tower shows no outward signs of decay, though it has withstood the ravages of time and tempest for possibly a round thousand of years.

Close by is the Church of St. Mary Magdalene, the original of which was also built by Robert D'Oily; but little or nothing of the original now remains. The church has the square Norman tower common to most Oxford churches, but compared with the grim severity of St. Michael's it is quite modern and ornate, with its open parapet, ornamental buttresses, and Decorated windows. The tower was, in fact, rebuilt in the 16th century, the older part of the building dating back to the reign of Edward II. The church, curiously situated on a kind of island in the middle of the road, owes to this fact its somewhat peculiar plan, for, being bounded east and west by the roadway, extension in either of these directions has been impossible, and enlargement has had to be effected by the addition of north and south aisles. This peculiarity obtained for it the nickname of "The Archipelago"

Opposite the north door of St. Mary's is the graceful Martyrs' Memorial, in the style of the Queen Eleanor crosses erected by Edward I. Facing the Memorial is the picturesque and creeper-covered west front of Balliol College, extending northward till it adjoins the equally picturesque St. John's College, which is half hidden behind a splendid row of elm trees. Of all the lovely gardens in Oxford, St. John's College garden is perhaps the loveliest. Lying far back from the road, from which it is separated by two quadrangles, the garden on a summer afternoon presents a spectacle of ideal peace and loveliness, with its green velvet lawns bathed in sunshine, its flower borders aglow with colour, its venerable trees, its rockery, and, on its western side, the lovely garden front of the college, with its oriel windows looking out through a veil of greenery.

South of St. Michael's is the interesting tower of St. Martin Carfax. This tower occupies the site of the oldest parish church in Oxford of which any record can be traced. Of the main building no vestige remains, but the tower, supposed to have been built in the reign of Edward III., but showing traces of a much earlier date, has been preserved as a clock tower, and is one of the most conspicuous objects in Oxford, standing in the heart of the town, at the junction of the four main thoroughfares. The stranger in Oxford, taking it for a church, looks vainly for the entrance, and is mystified to find none. There is something impressive about this solitary tower standing among the shops in the busiest part of the town, preserved, not for its utility, but for its picturesqueness and historic interest. In the church of which this tower once formed a part, Shakespeare is said to have stood sponsor to Sir William Davenant, who vaingloriously claimed a closer relationship with "Sweet Will."

Further south, its grounds bordering on the river, Christ Church College, the chapel of which is also the Cathedral Church, is one of the smallest cathedrals in England, but nevertheless one of the most interesting, both historically and architecturally. It occupies the site of a convent founded by St. Frideswide, who died in 740. At the east end of the north aisle are the remains of a Saxon arch, and close by is a part of the shrine of St. Frideswide. A fascinating feature is the lovely fan-tracery of the roof of the choir. The prevailing style is Norman, and in the chapter-house is a splendid specimen of a Norman doorway; but much of the work is Early English, the church being very interestingly representative of the transition. Its fine Early English tower and spire give the city half its character, but the other side of the great quad, the famous Tom Tower, built by Sir Christopher Wren in 1682, does not now look like a mere modern upstart.

The High Street, thanks to the town-planing authority vested in the University, is an imposing thoroughfare, lined with noble buildings. It is dominated by the spire of St. Mary's Church, which, with its fine facade surmounted by a row of pinnacles, its beautiful porch supported by twisted columns and crowned with a figure of the Virgin and Child, and its magnificent Decorated spire, is, for most people, one of the finest specimens of architecture in Oxford. The original building is one of the four Oxford churches mentioned in Domesday Book, the other four being St. Michael's at the North Gate, St. Peter's in the East, and St. Martin Carfax—but the greater part of the present church was built in the 13th century, in the Decorated style then prevalent; the spire, with its cluster of turrets and pinnacles at the base, having been added some years after the Early English tower was built. St. Mary's, with its profusion of ornament, is the antithesis of St. Michael's, with its aggressively utilitarian aspect. Perhaps the loveliest feature of St. Mary's is its unique porch with spiral columns, the beauty of which is enhanced in summer by a curtain of creeper. The figure of the Virgin and Child over the porch are of the few "graven images" which escaped the general destruction at the Reformation. Close by is the graceful spire of All Saints' Church, a comparatively modern (early 18th century) building in the Classic style, occupying the site of a very ancient church of the same name. More interesting, from an archæological point of view, is "Ye Ancient Church of St. Peter-in-the-East," situate in a lane just off the High Street. This is one of the churches mentioned in Domesday Book, but the greater part of the present building was erected in the 12th century. Under the chancel there is an interesting crypt, of earlier date than the church above it. There is also a splendid Norman doorway in the south wall of the church. The lane in which this church stands is itself very interesting, skirting as it does the old eastern wall of the city, and spanned at one point by a beautiful Norman arch.

Between the High Street and Broad Street lies an extremely interesting group of buildings forming the heart and nucleus of classic Oxford. This group includes the Sheldonian Theatre, with its octagonal cupola commanding a beautiful view of the city, the Bodleian Library, the Divinity School (said to be the most beautiful interior in Oxford), and the Tower of Five Orders, in which the Tuscan, Doric, Ionic, Corinthian and Composite columns are superimposed. The High Street culminates in the glory of Oxford—Magdalen College, with its incomparable tower, surmounted by four pinnacles, standing on the bank of the river like the guardian spirit of the town. The tallest, the most conspicuous, and the most perfect of all Oxford's towers, it is a landmark for miles around, rising high above all the other buildings, overlooking the city like a fair sentinel. In conjunction with the river and Magdalen Bridge, it makes an exquisite picture.

Two other extremely interesting colleges are the two which present perhaps the greatest contrast—New College and Keble College; the former almost the oldest, the latter almost the newest, college in Oxford. New College is very, very old. Its most interesting feature is the fragment of the old city wall forming the boundary of the college garden on its north and east sides, the College being built in an angle of the wall. Very hoary and venerable is this old wall, with its platforms where the sentinels used to keep watch, approached by steps hewn out in the thickness of the wall. At one corner of the wall stands the bell tower, at some little distance from the chapel itself. This tower is of a semi-military character, almost as severe in design as that of St. Michael-at-the-North-Gate, of which it is a 14th century counterpart. The chapel is perfect in proportion and simple in design, all over-elaboration having been scrupulously avoided. In the ante-chapel is the famous sepia window by Sir Joshua Reynolds, perhaps the most beautiful window in Oxford.

Very different in kind, though scarcely less in degree, is the attraction of Keble College. Here the charm of antiquity and tradition is altogether wanting. The college is in fact almost glaringly new, yet with a beauty of its own which may challenge comparison with any other college in Oxford. Erected in the 19th century, it marks a departure from the traditional style of architecture in Oxford, being the only college built of brick. The chapel is of extraordinary height. Its walls covered with brilliant mosaics, its windows filled with stained glass, it is full of light and colour.

Just beyond the railway station, in the extreme S.W. corner of the city, and hidden behind a huge marmalade factory, is the interesting little old church of St. Thomas-the-Martyr. Built in the 12th century, it is a typical Norman church, with its squat square tower of rough grey stone, and its general air of solidity—a church to delight the soul of the antiquarian. Standing in its quiet churchyard, one might almost fancy oneself back in the days of King Stephen.

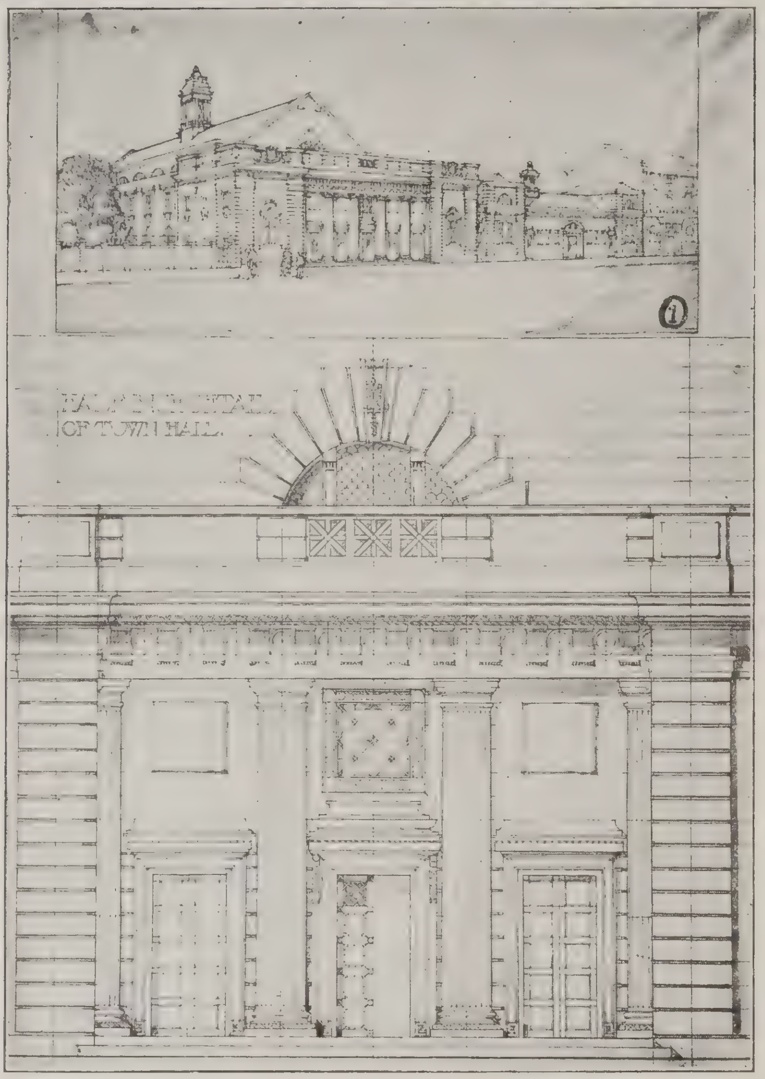
From St. Thomas-the-Martyr to St. Barnabas—from the reign of Stephen to the reign of Victoria—is a far cry; from St. Barnabas to the Saxon tower of St. Michael-at-the-North-Gate, a still further one; and as the mind goes back over the centuries to those remote Saxon times, one realises that in Oxford we have an epitome of the great events of English history, and of the history of English architecture, since the days when the inhabitants of the city watched the tower of St. Michael rising stone by stone above the northern gate of their city.

STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION.

Clause 3 of the conditions of this competition reads: "It is the intention of the Council to accept the award of the assessor, and to entrust the carrying-out of the work to the author of the design which he may select, unless a sufficient reason exists to the contrary. The Council does not, however, bind itself to carry out any one of the designs submitted." Then Clause 4 reads: "Subject to Clause 3, the author of the design placed first will receive the commission for carrying out the work. The authors of the designs placed second and third will receive respectively the sum of £100 and £50;" while Clause 6 reads: "In the event of the Council's giving no instructions to proceed with the work within twelve months of the award, the selected architect will be paid the sum of £200, which sum will merge into the commission of five per cent. if and when the buildings are carried out; or if, for any reason, the scheme should be entirely abandoned or not proceeded with within five years of the award, he will be paid the sum equal to one and a quarter per cent. (less the above-mentioned £200) upon £25,000, the estimated cost of the building."

The Council, notwithstanding the award of the assessor, Mr. Leonard Stokes, F.R.I.B.A., have, as stated in this Jorunal a fortnight ago, only allowed a premium to the competitor placed second, finding "a sufficient reason" for their action ready to hand in the fact that the building cannot possibly be erected for the money specified. The uncertain nature of the subsoil involving the carrying down of the foundations to at least 10ft. below the present surface of the ground, and the extent of the accommodation required, make the sum that is available (£25,000, from which £1,000 has to be deducted for an organ) quite inadequate, and we think this should have been obvious to the Council from the first. In any case their treatment of the authors of the design placed first and third is to say the least of it unsatisfactory.

The accommodation required in the extension to the present buildings consisted of a hall capable of seating 3,250 people, including galleries, with cloakrooms and lavatories, etc., for both sexes. The entrances were to be "ample and convenient," and exits capable of emptying the whole of each section of the hall in not more than three minutes were to be provided. It was specially desired that the acoustic properties of the hall should be carefully considered, and the use of columns avoided. The existing main entrance was, if possible, to be utilised as one of the principal entrances to the new hall, and the present staircase so remodelled as to form a more satisfactory approach to the existing assembly room. Cloakrooms, etc., which could be used in connection with this entrance, were to be provided. Space was to be allowed in the hall for an organ, and sufficient accommodation for the necessary machinery. A platform, capable of extension by movable portions, both in front and as regards the tiers for chorus, was required to be shown, and two adequately fitted dressing-rooms for artists as well as two for chorus, were to be provided. A new room was required in direct communication with the present assembly room, and of about one-third its area. For the purpose of serving banquets in this room or in the existing assembly room off it, a properly equipped kitchen, with all requisite lifts, etc., and serving-room was specified as necessary, also



STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. FIRST PREMIATED DESIGN. GARRATT AND SIMISTER, ARCHITECTS.

The best portion of Messrs. Garratt and Simister's elevations is seen in the half-inch detail. It is far in advance, in actual composition and rational restraint, of the bulk of English town-hall designs.

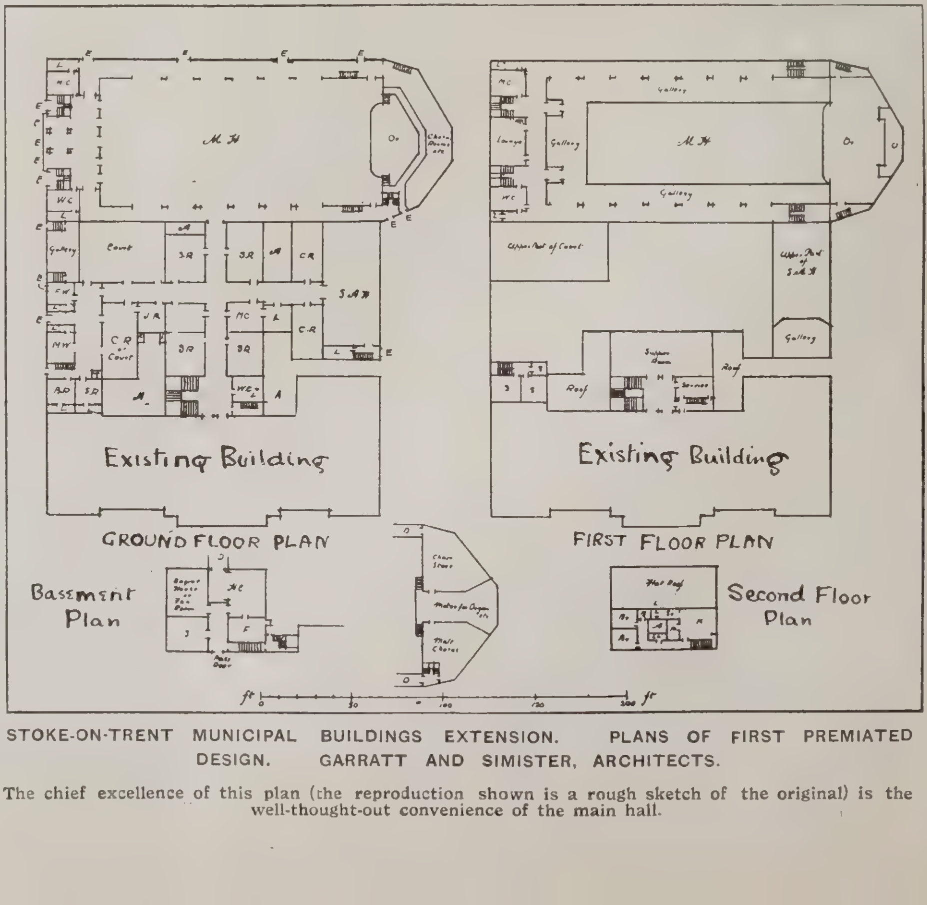
a court room for police and county court purposes, of about 1,800ft. area, with small public gallery, together with judges' retiring room, barristers' retiring room, telephone room, witnesses' room, lavatories, etc.; a committee room of about 800ft. area, in close proximity to the above court room; a small assembly hall, area about 2,000ft.; ante-room and two committee rooms opening off same. (These committee rooms were to have an area of about 500ft. each. A small gallery was to be provided in the assembly hall, with separate entrance, if possible, from outside, and with adjacent lavatory accommodation); four spare rooms of about 500ft. area, within easy reach of the small assembly hall and court room.

A suggestion embodied in the conditions was to the effect that the entrances and approaches to the court room and small assembly hall should be kept as far as possible separate from the main entrances to the large hall, so that the portions of the building could be used at the same time for different purposes without interfering with each other. All buildings at present on the actual extension site could be removed, though it was stated to be desirable that the mortuary and stable buildings should be retained if this could be done without in any way sacrificing the arrangements adopted in competitors' plans. Finally, if in adding to the present building any of the existing office or other accommodation was interfered with, similar accommodation had to be provided either in the old or new building. In or adjoining the latter suitable provision, including store rooms, was to be made for a resident caretaker.

The drawings required included a plan of each floor, two elevations, and at least two sections, all to a scale of 16ft. to 1in.; a detail of a portion of the part toward Tower Street, to a scale of 2ft. to 1in.; a perspective view showing the Tower Street front, in which the actual width of the building was to be fifteen inches. The method of finishing the latter was left to the discretion of the competitor. The elevations were to be in black and white, only without shading, the windows being coloured grey.

In the majority of the schemes submitted one of two types of plan seems to have been followed—either the main hall is placed at the back of the site, with the rest of the accommodation in between it and the old building, an arrangement usually treated as an absolutely new departure, not required to harmonise with the existing block; or the main hall is placed centrally, with the small hall and court balancing on either side. This disposition offers a chance of presenting symmetrical elevations to the side streets.

The first selected design is the work of Messrs. Garratt and Simister, Congreve Street, Birmingham, to whom the sum of £200 would, in the anticipated course of events, have been due as premium. The chief excellence of their plan is undoubtedly the well-thought-out convenience of the main hall, whose only practical defect appears to us to be the inadequacy of the crush hall at the front. But in the disposition of the remainder of the accommodation we do not think the authors are quite so consistently successful. The arrangement generally would bear revision. Thus, however ingeniously the court itself may be placed, it is surely not altogether desirable that the barristers and solicitors should be forced to traverse a long corridor to reach their destination, whilst the provision of separate rooms for male and female witnesses appears to us to be needless, and was not asked for. It is hardly possible also not to take exception to the placing of the small hall along the aqueduct street side of the site, with a small entrance to the gallery only from this street. The main entrance to the small hall is through the main building, by way of a long corridor, which cuts at right angles through the chief axis corridor of the building. Should the large and small assembly halls happen to be used at the same time, the confusion resulting from the two intersecting streams of traffic can be easily imagined.



STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. PLANS OF FIRST PREMIATED DESIGN. GARRATT AND SIMISTER, ARCHITECTS.

The chief excellence of this plan (the reproduction shown is a rough sketch of the original) is the well-thought-out convenience of the main hall.

Of Messrs. Garratt and Simister's elevations the best portion appears to us to be that of which we reproduce a half-inch detail, and whilst it would not be reasonable to describe it as thoroughly matured work, it is yet far in advance, in actual composition and rational restraint, of the bulk of recent English town hall designs. The central voussoirs of the arch under the gable seem to call for reconsideration, and the almost Dutch key-block scroll is hardly fortunate, though fashionable. The pierced balustrade is also, to our way of thinking, altogether too thin; but it is, after all, a perfect godsend to discover that native designers here and there are waking up to the fact that such motives actually exist.

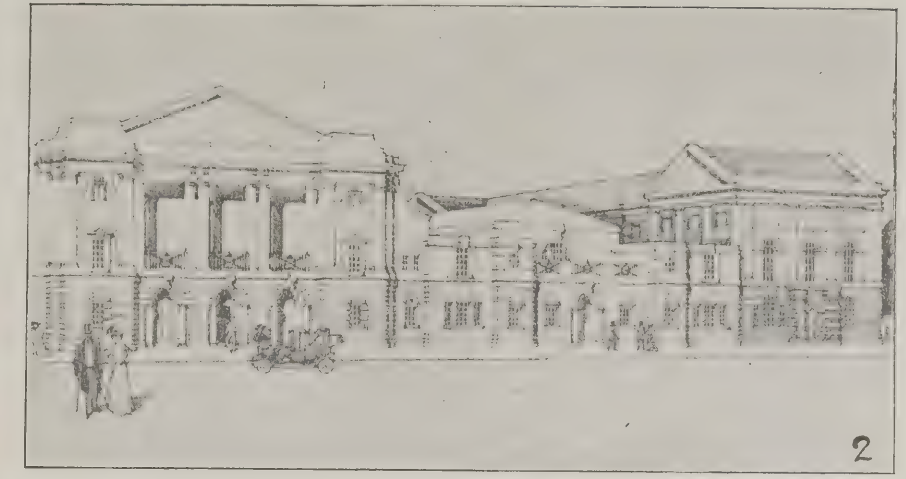
Messrs. Warwick and Hall, 11, South Square, Gray's Inn, London, W.C., placed second by Mr. Stokes, have evolved a plan distinguished by several pleasant features, and with the additional advantage of being more economical than either of the other two premiated schemes. As in the two latter, it will be seen that the main hall is placed parallel to the existing municipal buildings, and at the back of the site. The authors have managed to keep within the line of Aqueduct Street, and thus have effected a considerable saving. However, we think that this advantage over the first selected design is counteracted by the fact that the hall is, on the whole, not so well proportioned and completely thought out as in the latter, though its apsidal end would undoubtedly be a pleasant feature in itself. But in the arrangements of the other parts of the scheme the authors appear to us to be exceptionally fortunate. It will be seen that the small hall balances the court, and the treatment of both shows careful consideration and competent handling. Generally, we think the whole plan to be characterised by refreshing simplicity, and to be a genuinely straightforward and convenient solution of the problem. It is precisely this fact which makes it so difficult to reconcile plan and elevations in this design. We do not like the elevations.

The scheme placed third, that of Mr. W. Haywood, Norwich Union Buildings, Congreve Street, Birmingham, possesses a well-shaped main hall, which suffers somewhat, perhaps, from the large area necessarily occupied by the gallery and orchestra. The general distribution of the rooms appears to us to be good, though a trifle extravagant. The elevations show a decided French influence in parts, and if on that account alone are meritorious. The facade to Tower Street is, in our opinion, infinitely the best, though the return block is, on the whole, a pleasant piece of composition, and shows that the designer has a genuine feeling for mass, and something approaching a real technique in the handling of it.

In the bulk of the other designs submitted, the chief variation in plan from those selected, consists in the placing of the main hall in the centre with the small hall and court flanking it on either side.

A general survey of the exhibits intensifies one's regret that in this country it is so little realised that axial arrangement and balanced symmetrical disposition, together with careful attention to the obtaining of beautiful shapes in halls and rooms, produce not merely planning which is architecturally admirable, but which is also the most satisfactory from the point of view of efficiency, convenience, and economy. The circulation amongst the profession of the recent American and Beaux Arts publication dealing with monumental design would, we feel, do a world of good, and help in some measure at any rate to save us in the future from meriting American scorn of our parochial conception of civic architecture.

A commemorative banquet in connection with the International Correspondence Schools is to be held at the Hotel Cecil on Saturday, September 18th, when Lord Montague of Beaulieu will preside, and many persons of educational, scientific, and business eminence will be among the guests.



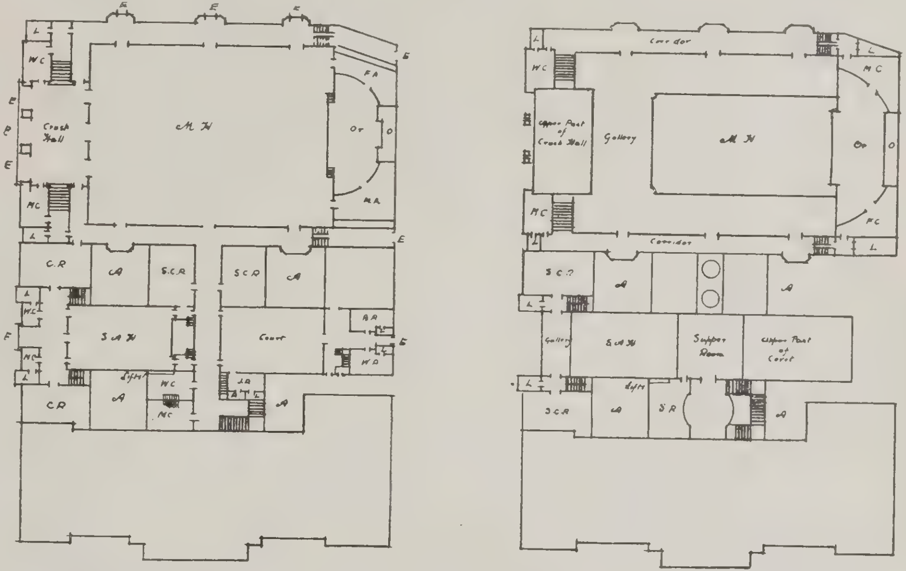
STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. SECOND PREMIATED DESIGN. WARWICK AND HALL, ARCHITECTS.

GOTHIC GROTESQUES.

Many of the grotesque ornaments in Gothic architecture depict the most ordinary affairs of every-day life. If a man had had cause to beat his wife, he may have taken a secret delight in perpetrating that fact, as at York, or if his wife had beaten him, that circumstance may have furnished the whim which produced the curious grotesques of Sherburne and Beverley Minster. There are many instances where the carvers have cut their initials as ornament, or shown themselves at their trade. Another homely subject often treated is the Ale-wife, who is either doling out imaginary beer to a thirsty carver, or has so provoked his ill-will as to be depicted as borne into the jaws of hell by a grinning demon.

The sculpture in the mediæval churches, Mr. Charles Collens, in "The American Architect" observes, was the picture gallery and library of most of the smaller towns. All that they ever saw of imagery was there, and it is conceivable that such frozen literature may have had its serious as well as its comic side.

The carvers of the Middle Ages all belonged to a guild of Masons, whose history runs far back among the earliest constructions. Thus many grotesques may be careful copies of certain forms which primarily were executed in all seriousness, but which, when copied by a later generation, found their original uncouthness merged into comedy. Such forms were almost in the nature of a Masonic trade-mark, and many of them can be traced back to a Hindoo or Pagan myth. It is for this reason that the earlier churches in England on which Italian and Flemish workmen were employed have grotesques almost identical with those found on the Continent. These early carvings deal largely with mythical characters and the symbols above referred to. Later the grotesque developed into adaptations from nature and curious fancies of all sorts.

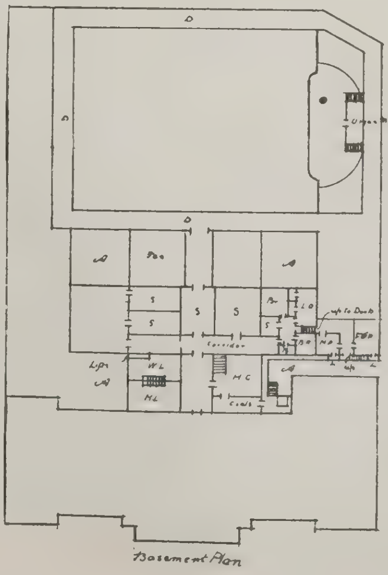


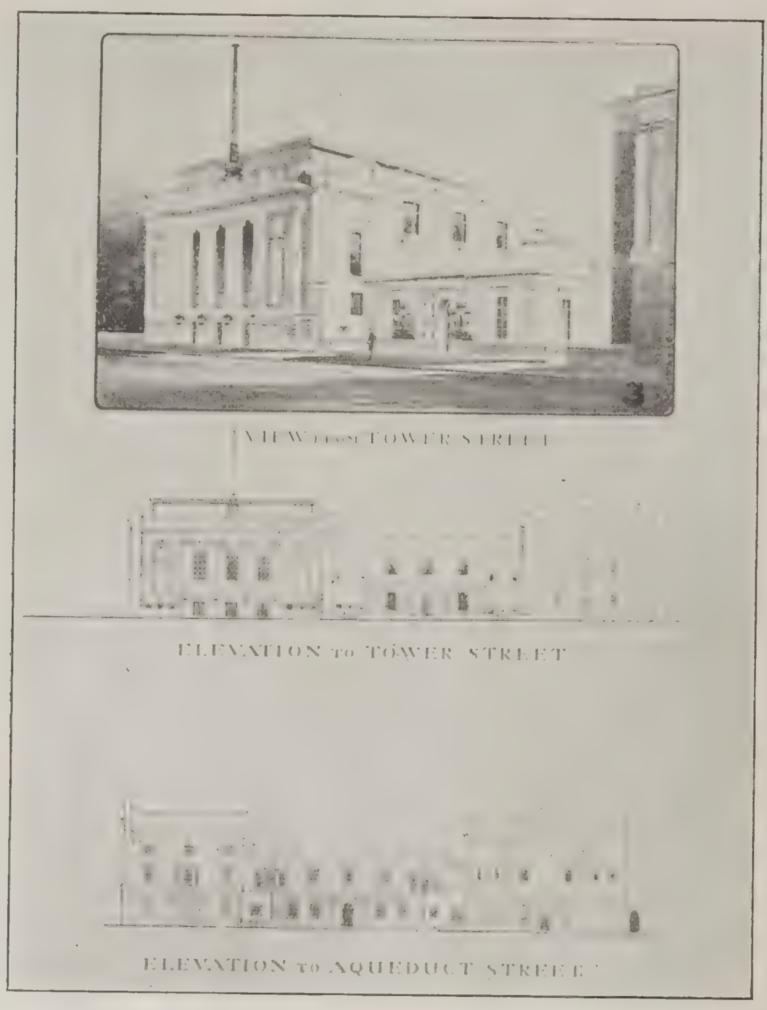
GROUND FLOOR PLAN

FIRST FLOOR PLAN

STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. PLANS OF SECOND PREMIATED DESIGN. WARWICK AND HALL, ARCHITECTS.

The authors have evolved a plan distinguished by several pleasant features, and with the additional advantage of being more economical than the other premiated schemes. (This copy is a rough sketch of the original)





STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. THIRD PREMIATED DESIGN. W. HAYWOOD, ARCHITECT.

The elevations show a decided French influence in parts, and it is evident that the author has a genuine feeling for mass, and a real technique in the handling of it.

By far the largest number portray the devil in various forms. The gargoyles, flying out from the cornices and buttresses, typify the driving of the evil spirits out of the church, evil spirits of all descriptions, some with birds' heads and claw feet, others with heads of animals and birds' wings, still others carrying off souls in their stony grasp. Such a mystical animal has a form well adapted to the long, slim character of the projecting waterspout. The upper parapets of Notre Dame de Paris have an intensely interesting group of demons, looking down over the hordes of the great city, ready to swoop like a flock of buzzards on the unwary. These figures are admirably carved, and must have been executed by a master hand.

The gargoyle, in countries where the rainfall is heavy, is long and highly developed, especially in Flanders, Northern France, and England. In the churches of Southern France it has small prominence.

The devil inside the church is largely confined to the capitals and corbels, and is usually busy making trouble for other people, or whispering evil advice into somebody's ear. When not thus engaged, he is frequently reaping the fruit of his efforts, and carrying souls into the jaws of hell. This awful place is a common subject, representing the future life of the evildoers in the maul of a horrible tooth-studded face.

In addition to these domestic and religious subjects, the carver had his fund of folklore to draw on for inspiration. Even Mother Goose figures in the grotesques of Beverley Minster and at Wells. Reynard the Fox symbolises the cunning of the clergy in many places. The cat, the dog, the pig, and mice all have their niches, some symbolic, others merely fancies.

Heads and masks were most popular for the corbels, as they could be readily adapted to the square form. Many a cornice shows an unbroken line of grimaces of every description. The mask is more popular in England than on the Continent.

During the Norman period the grotesques were numerous in the decoration, but the advent of early English limited the use somewhat. Later with the Decorated architecture in England, and the Flamboyant in France, the grotesque was at its height, and protruded its ungainly but interesting shape at every point of vantage. With the advent of Perpendicular the grotesque gradually fell away, and the carvers exercised their ingenuity in developing the intricacies of the canopy, and the armorial bearings, interspersed with rich foliation. The long unbroken lines of the Perpendicular left few capitals or corbels to decorate. The gargoyle also disappeared, since a more effete civilisation demanded that the water be carried off by some more modern method than down the necks of the passers-by. From this point the grotesque passes out of Gothic. In the Renaissance architecture it becomes a copy of the forms found in the Roman ruins, usually an ingenious combination of vegetable and animal, and is confined almost entirely to garden and fountain decoration. What grotesques appear in the treatment of friezes and capitals lack any humorous or symbolic element.

In the Flemish Renaissance they lived for a time, but merely as means of decoration, and, as in the case of the Italian, with no especial significance.

In England the grotesque as a natural product disappeared with the advent of Elizabethan Architecture. It has been revived there to some extent, but most of the modern examples are largely in the nature of caricatures.

In America they have only recently begun to use it as ornament. Sense of the fitness of things would hardly tolerate the carvings on modern Gothic churches that are commonly seen in the older buildings. The former spontaneity of such work has given place to a carefully studied model designed and executed under supervision and by trained workmen.

Modern architectural education has taught that the use of a building may be emphasised by its exterior treatment. This is really an outgrowth of French training, based on the exercise of logic in planning. Thus even in the designing of Gothic buildings the architect not only adopts a general form, which should express the uses of the buildings, but the smallest ornament is modelled with the same end in view. This method is exemplified especially in the new buildings of the College of the City of New York, the West Point buildings, and the new Union Theological Seminary Buildings.

The grotesques used in the College of the City of New York are admirable in their adaptability to the expression requisite for each building. The figures on the main building typify all of the various studies in a way which reminds one of the excellent work of Maxfield Parish. The gymnasium, chemical building, and mechanical arts building are all decorated with little gnomes, busily employed in imitating the various doings within in a way which is vastly entertaining. The grotesque work at West Point is much more conventional in character, modelled in planes, and yet in its way extremely interesting. Both are excellent in their way, and each well adapted to the particular style of Gothic which it adorns.

The secular element of the two groups above admits of the use of actual grotesque. The religious character of the Union Theological Seminary Buildings does not allow such freedom. The ornament there is very restrained, and the grotesques are confined to the library building and tower, depicting the various symbols of knowledge, with the owl, the sphinx and busts of monks typifying pedagogy, thought, research and preaching. The chapel building, while having various ornamental billet courses well adapted to grotesques, has been treated only with angels, cherubs, and evangelists. The ornament of the other buildings consists in armorial bearings or foliation.

The day of the grotesque in church decoration has gone by, but there is still a great field of interesting descriptive ornament to be worked out in domestic and public buildings. The active reintroduction of this element into our Gothic architecture is coincident with that logical movement which is gradually making every building speak for itself and every feature of that building have its *raison d'être*.

The contractor to whom the Llanelly Guardians gave a contract for a boundary wall to cost £595 13s. 6d., wrote to the Board that he had omitted to include £52 for excavating trenches, and was unprepared to sign the contract unless this extra charge was allowed. The Clerk stated that this estimate was still £61 below the next tender. A guardian proposed that new tenders be invited, but after discussion it was agreed to pay the extra £52.

* * *

A sale of land on an unprecendented scale is shortly to take place in Wiltshire. An area of 10,433 acres is to be sold, comprising whole villages. The villages intersecting the estates, together with the village inns, shops, manorial rights, with the lordship of the manor, and certain advowsons are to be sold just as they are. It is years since a sale in lots even approaching such size has taken place. The villages concerned in this huge sale are those of All Cannings, Steeple Langford, Stapleford, and Winterbourne Stoke.

Houses in Square Formation.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—On p. 151 of your issue of August 25th, you publish a design for four cottages built in the form of a square around a central light well, and invite criticism of same. In the first place, if it were desired to build them in Manchester, I might say that it could not be done. The by-laws would not allow, and the following are two or three of the reasons. (1) The width of open space at the rear of each house is not sufficient. (2) The area of paved yard space, which must also be at the rear of the houses, is insufficient, and also does not extend the whole of the lateral width of the houses. (3) All drains must be outside the curtilage of the proposed buildings. In this case they would not be. With regard to the drains, the whole of what might be termed the internal roofs would have to be drained into the light-well. All four w.c.'s, and the four baths and lavatory wastes would also have to be drained into the same well, as would also the sink wastes from the scullery sinks. All these drains into 7ft. 6in. square, twenty ft. below the roof, and enclosed on all sides.

The pantry, which is, I presume, the only keeping place in the house, would have a window or a ventilator opening into the same well, in which the air would be stagnant and bad from the wastes and other drains.

Again, the whole of the most obnoxious part of the drainage would have to pass under one of the houses, which, according to present day sanitary arrangements, is exceedingly bad. It is stated that one pantry would have French casements, to allow for cleaning the well; which implies that if anything went wrong with the drainage, one house would have all the trouble—all the dirt and most of the smell; besides which, the people in this house would have the greatest chance of ill-effects, such as sickness, etc.

Taking into account the practicability of the houses; in the first place, the coals are in a very awkward position, and to get coal in, which at the most would be only 3 or 4 cwt., one has to pass across the kitchen hearth and through the scullery, or through the living-room and through the scullery; in either case a most unpleasant way for the housewife; for even if they are only cottages, the housewife ought to be considered.

The kitchen also is rather awkwardly planned. The door opening direct from the vestibule on to the fireplace is decidedly bad, and the fact of the scullery and living-room doors opening on to the fireplace from the other side makes the room an uncomfortable one. The idea of opening the front door and entering the living-room in the way as shown, or proceeding upstairs direct from the street, is not a method that commends itself, and reminds one of London cottage flats, or the two up and two down cottages of the North of England.

In dividing up the bedroom plan, there is a slight amount of juggling with the living-room fireplace, and what I take to be the wash-boiler or copper flue, to form a fireplace in one bedroom; from which, along with another fireplace, is carried up a six-flue chimney stack.

In considering cost of building, the arrangement as shown would, I think, be the cheapest; but a row of four cottages with the same accommodation would be more sanitary.

The roof in the design shown would tend to increase the cost slightly, and would cost much more for labour than the row would for roofing.

The fact of the roof cutting down into the bedrooms would, of course, lessen the cost of building considerably; but in some towns and urban districts this would not be allowed.

Taking the scheme as a whole, I do not consider it practicable. As for saving space, yes, it would; but I rather think the cost of roadmaking would counteract the cost of the land or space saved.

R. THOMASSON.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—In your issue of the "Builders' Journal" dated August 25th, criticism is invited of a design for four cottages arranged round a central well.

That the design is intended solely for the basis of criticism I am anxious to believe. So let me treat his design lightly, daintily, and playfully.

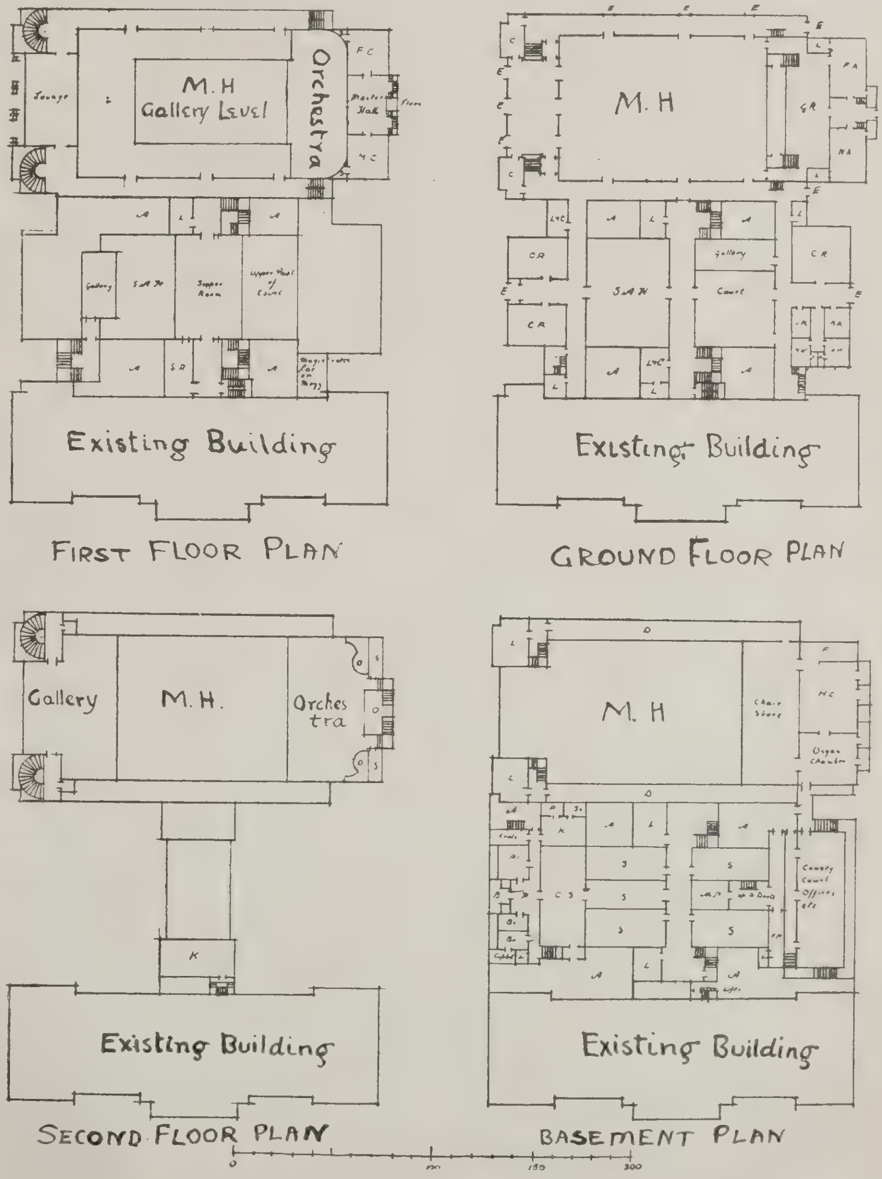
The position of the north point in no way affects criticism. Twist it about as one may, the more advantageous it is to one cottage the greater disadvantage it is to the other. The cottages with the S. and E. or S. and W. living-rooms will have south kitchens, the horror of horrors to the housewife. The cottages with the ideal north kitchen will have N.E. or N. and W. living-rooms, where hardly a ray of sunlight will enter the whole year round. North bedrooms will abound. In fact, it is most humorously heartrending to place the plan in all positions round the compass and note the neutralizing influence of two of the cottages to the joys of the other two.

None of the sculleries get any direct (and they get very little indirect) sunlight. If there's a pleasant view, two of the cottages will revel in it, and the tenants of the remaining two will doubtless get a reduction in rent because of the omission.

The rooms, it is said, are "worked to make the length equal to the diagonal of the breadth." It was too interesting a point to miss, and I thank the author for the thoughtfulness that involved only square roots and not cube roots. Surely such a definite statement ought to convey accuracy, yet, taking the measurements literally, and wading through the rider on Euclids, Prop. 47, Book 1, to check the lengths of the hypotenuses, I found that only the dining-room in each cottage approximates to this proportion—and only approximates. As a general guide for a proportionate room, this is excellent advice, but woe to the designer who makes it a *sine qua non*. Rules like this are apt to become an obsession to the ruin of planning, which should suit individual sites before anything else is considered.

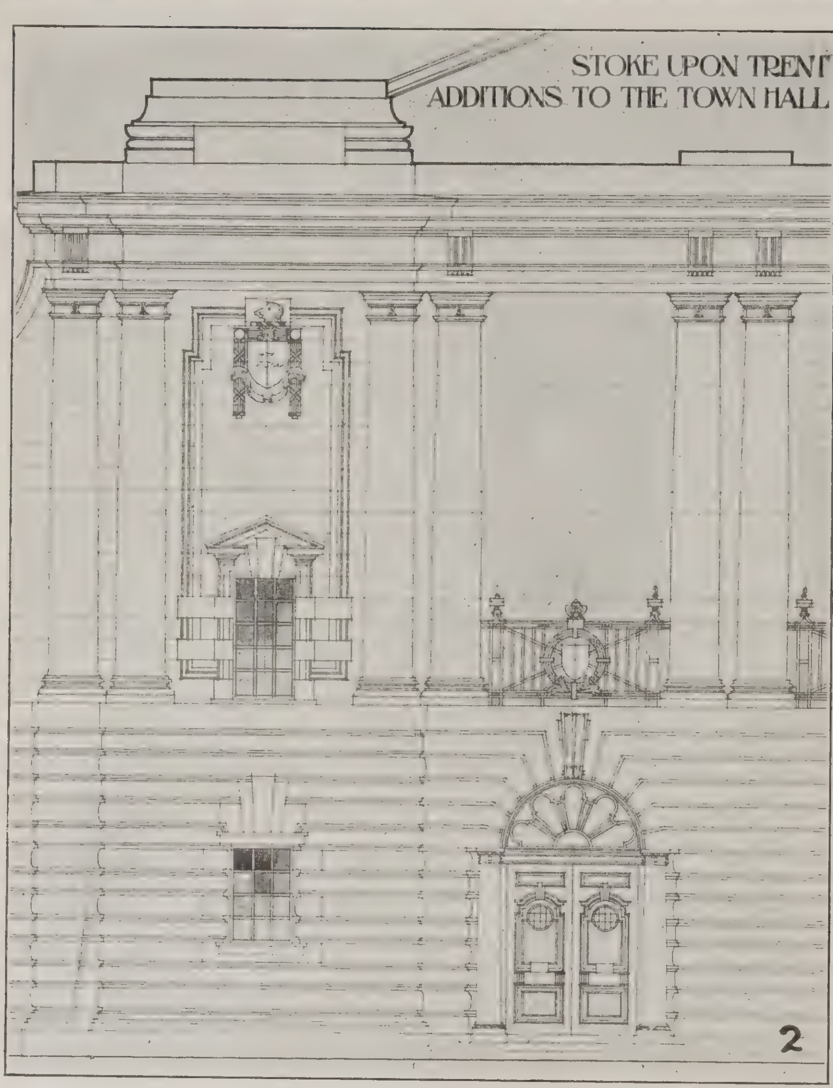
Both kitchen and living-rooms are absolutely without comfort and restfulness. There is nowhere near the fireplace where, on a cold day, one could sit without being in a draught. Doors at either side of fireplace, direct traffic across working or sitting parts of room, as these are planned are the *bête noir* of successful planning. In fact, both rooms are types of what to avoid.

To store coals, the carrier has to go



STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. PLANS OF THIRD PREMIATED DESIGN. W. HAYWOOD, ARCHITECT.

The plan (of which this is a rough sketch) shows a main hall of good shape, which suffers somewhat, perhaps, from the large area necessarily occupied by the gallery or orchestra.



STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. DETAIL OF SECOND PREMIATED DESIGN. WARWICK AND HALL, ARCHITECTS.

through kitchen or living-room, whilst the position of fireplace and copper against the coal and fuel store would tend to produce spontaneous combustion.

All sculleries would be dark and ill ventilated. All pantries are ventilated from the small enclosed sewage works called the central well.

Heavy at heart but full of hope, I mount the stairs of thirteen steps in one flight, lit and ventilated by that objectionable feature called a skylight, the lower part of which is in a line with the outlets of four soil ventilation pipes to the drains.

It is pleasant to record that the bedroom plans are very satisfactory in themselves excepting aspects. Still, as it is planned, four bedrooms out of the nine would get the health-giving sunlight.

All the fireplaces are carefully arranged for the satisfactory grouping of the flues into one stack; and if the author of the design had not found it necessary to carry up his stacks through the valley rafters, thus forming double chimney gutters, they would have been even happier.

The chimney caps and placing of pots look weird and unstable; but, judging from the drawings, the flues seem to draw well by this method.

The basement plan calls for no other criticism than that it is, of course, at the root of the troubles.

The roof plan, apart from the necessity of special made valley tiles, or some sort of lead gutter would be required for the intersection of lower part of Mansard roof with the main roof, is satisfactory and economical. Has the author any reason for showing the projecting gables hipped on elevation and sections and not on plan? It seems rather incongruous.

With regard to by-laws, the author has evidently designed the cottages for some out-of-the-way district where such troublesome things are not heard of.

Otherwise I know of no by-laws which would allow the buildings to be erected as planned. I can remember none which has not the clause to the effect that every dwelling house must have at least 15ft. in the rear (and the full width of the building) clear free from any buildings and belonging exclusively to such dwelling. I quote from memory; but such is the gist of the clause. The discrepancy of the plan under cussion is obvious on inspection. A central well, 7ft. 6in. square, is common to all and belonging to neither. To take one's turn in cleaning the well the tenant has to pass through a neighbour's house.

Some districts allow the drainage scheme to be amalgamated as shown, but many do not; and, as planned, it is most unsatisfactory both from its difficulty of access, and from the fact that all baths, lavs., sinks, discharge into the light and ventilation well to the parts of the cottages most needing it; to say nothing of a manhole receiving the combined discharges of the sewage of four cottages under one's nose and in such a confined position.

One can imagine a veritable inferno of noise here at times, plainly audible throughout all the cottages. Drains as shown underneath floors are not ideal in cottage planning especially.

The elevations are the logical outcome of the planning, and as far as can be judged from scale drawings, are æsthetically pleasing.

As to saving of space, the phrase is unsuitable if not wrong. One does not expect, or see, economical cottages covering great areas of ground, and these must be considered analogous to such.

As to space between groups, the only ways that occur to me of building these cottages are between two roads, or by approaching the two rear cottages by means of a path the length of the front gardens, common to both rear cottages in adjoining groups. The only way to obtain space between the two groups is by making the gardens longitudinally parallel to the roads, and the greater or lesser length of garden, which fixes the distance between the groups, fixes also the number more or less of cottage facing the roads, with their necessary initial expense and upkeep to pay for. It is always possible to get air space if one eliminates what it involves, and in this case the getting of air space is not consistent with economical laying out.

The most satisfactory way I have come across of laying out cottages to obtain air space combined with economy is on the chequer-board plan. This method of laying out involves neither loss of aspect, advantages of site, or extra expense in road making.

I congratulate the author on an adaptable temperament which laughs at precedent, and I beg him to believe that I am painfully aware how much easier it is to criticise the evolved than to evolve the would-be criticised.

S. Pointon Taylor (A.).

[The above letters have been submitted to the author of the design, who, it will be remembered, expressly invited criticism of his experiment. He observes that, "The cottages would doubtless require to be erected outside many Council areas, but that does not say that there is anything unsanitary in the idea of the well and central drainage. It would be interesting in this connection to have a legal definition of the rear of such a block. If proper vent pipes were carried to roof, there should be no smell in area. The aspect, of course, is the most serious difficulty, and the block undoubtedly would only be suitable for selected sites."]

Hardships of Tendering.

To the Editor of The Builders' Journal.

Sir,—The particular case to which your correspondent "Heating Engineer," in your issue of September 8, directs attention, as one of the many hardships of tendering, doubtless refers to some instance in which either the scheme itself was laid down and the various contractors had to take off their own quantities, conforming to the requirements of a specification, or in which bills of quantities were supplied, from which estimates had to be prepared.

There is, however, a much worse feature than this—I refer to those cases where schemes and estimates for heating and ventilating installations have to be prepared by the various contractors themselves. In such cases, more often than not the lowest tender is accepted, without regard to the value offered for the amount asked for. To accept the lowest quotation, irrespective of the relative merits of the various schemes, without regard to efficiency, economical working, and low maintenance expenditure is neither just nor wise.

Another hardship is that after a contractor has taken the trouble to prepare an estimate (with probably a scheme as well), he in many cases receives no notification of the fact that he has been unsuccessful; and if he has the temerity to write and ask for this information, and incidentally asks for a list of the tenders submitted, he receives too often a curt reply. A letter recently received from a town clerk is to the effect that "it is not the practice of the Corporation to supply unsuccessful tenderers with a list of the tenders submitted."

In fairness to the architectural profession, I must say that, taken as a whole, they give the various contractors as much information and help as they can. The architects themselves, in most cases, strongly object to having to accept the lowest tender irrespective of all other considerations; and when allowed a perfectly free hand they recommend acceptance, as previously stated by "Heating Engineer," of a tender which in their opinion is most satisfactory, clearly recognising the force of the maxim that if you pay less you get less.

CHAS. F. H. NIGHTINGALE.

South Kensington.

Builders' Locked-up Capital.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—Your article under the above title calls attention to perhaps the most cruel grievance from which builders and their sub-contractors suffer.

The worry and anxiety involved in getting settlements is never ending, and most injurious to those responsible for the financial arrangement of firms in the building trade; and no means at present exist to prevent the delays in settling for finished work.

Apparently the persons chiefly responsible for these delays are architects, especially those who undertake both the architectural work and the quantity surveying. Many architects seem to have their minds so keenly set on the new work, in hand or in the air, that they cannot find time to settle accounts until they are worried or shocked into it by some very plain speaking from the builder or the client.

Surely, in the face of the instance to which you referred, and which is only one of many, it is time that the architectural profession came to some understanding with the building trade, which should put a stop to the evil of unduly delayed settlements.

Yours faithfully,

A. G. W.

BERKSHIRE COUNTY COUNCIL OFFICES, READING.

This open competition resulted in a collection of no less than 177 designs, of which the majority were well above the average of the class of work usually submitted for this kind of building, and amongst them were to be found the drawings of many of the leading members of the profession. The popularity of the competition may be attributed to the fact that the premiums offered were rather above the average, being £100 for the first, and £70 and £50 for the 2nd and 3rd respectively, while the cost of the building was not to exceed £16,000; and also, no doubt, the profession felt every confidence in the appointment of such a competent and experienced assessor as Mr. Mervyn Macartney.

The site is situated in the Forbury, overlooking the Gardens, and between the Sessions House and Messrs. Sutton's premises. The County Council requested the president of the Royal Institute of British Architects to appoint the assessor; and the conditions issued said: "Mr. Macartney will place the designs in their order of merit; but the Council is at full liberty to select the design it considers best suited to its requirements."

This clause, very properly, the R.I.B.A. took exception to, as it practically set the assessor's decision at nought. After considerable delay it was decided that this clause should be altered, and that the Council should undertake to employ, in the event of the work being proceeded with, one of the three first architects so placed by the assessor.

The site presented many difficulties, having only 64ft. frontage and being 93ft. deep, and a certain amount of space being available in the existing Assize Courts. The rights of light were very awkwardly restricted, only the middle portion of the west elevation being available for windows, and all windows facing south or west having to be constructed so that they should not open for a height of 6ft. above the floor. The drawings required were a plan of each floor, four elevations, two sections, all to a scale of 8ft. to an inch, and a detail of a portion of the front elevation to a scale of 2ft. to an inch. No perspective was admitted. The drawings were to be in pen and ink, and the elevations had to be coloured to indicate the materials to be used.

The elevation of the Forbury was to be brick, with Portland stone dressing, to the east (up to the Assize Court), to be left to the discretion of the competitor, the west and south elevations to be red brick.

The accommodation required was to include: Clerks' department, with an area of 3,005 super ft.; education secretary's department, 3,670 super ft.; medical officer's department, 1,025 super ft.; county treasurer's department, 2,035 super ft.; county surveyor's department, 1,715 super ft.; and the land steward's department, 825 super ft. In addition there were to be two committee rooms, not less than 600 super ft. each, one of which was to be on the same floor as the education department. Storage accommodation for 40 bicycles was to be provided.

The first premium has been awarded to Messrs. Warwick and Hall, of Grays Inn, London, W.C., the second to Mr. E. F. Shrewsbury, of Maidenhead, and the third to Messrs. Wills and Anderson of London. The competition has been won, as was a foregone conclusion in the case of a building for this purpose, by its plan. It must have been much against the assessor's feelings to have to disregard some of the excellent elevations submitted because their plans did not absolutely meet the requirements.

No one, on careful examination, can dispute the fact that the plan placed first is far and away the best of the three premiated designs. It is a good symmetrical and economical plan. Access to all parts of the building has been well considered. The stairs and lift are in quite the best position, and the area, although not unduly large, is, as arranged, sufficient to do its work. On the whole the plan is well lighted, but all the doors in the corridors are not quite so good in this respect as in the plans placed second. A good effect is obtained in the front rooms on the ground floor by the windows being placed in alcoves. It is not obvious how coals can be delivered into the cellar, or how the bicycles will be got into their store-space (which, by the way, hardly appears sufficient for 40 bicycles), as it appears the only access to these is by a lane, which is the private property of Messrs. Sutton's.

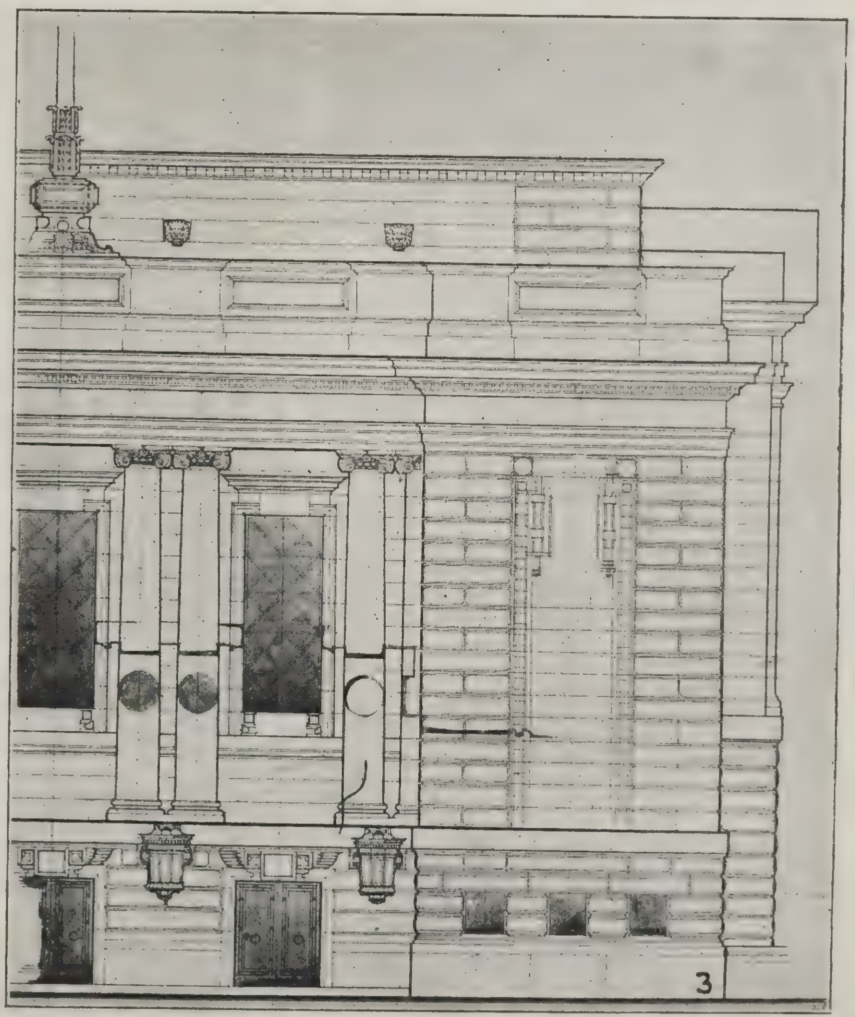
The small frontage, and the fact that 4 floors were necessary to provide the accommodation required, presented a serious difficulty; the height of the front elevation was sure to be too great for its width.

The first design gets over this well, a dwarfing effect being obtained by strong horizontal shadows under very bold eaves, and also under the Doric order, which runs through the centre of the façade. This screen of twin columns will certainly look well when built, and is a strong point of the design.

The proportion of the windows themselves, and also of their divisions, has been carefully treated, with a satisfactory result.

The other elevations are suitable, but the conditions do not appear to have been adhered to absolutely, red brick only being specified, but stone dressings having been used. It is doubtful how successful the treatment of the recess on the side elevation may be in perspective. The drawing appears to indicate the face of the wall lining up with the face of the long dormer above it.

It would have been interesting to see both in the 1st and the 3rd designs the proposed treatment of the portion of elevation return-



STOKE-ON-TRENT MUNICIPAL BUILDINGS EXTENSION. DETAIL OF THIRD PREMIATED DESIGN. W. HAYWOOD, ARCHITECT.

ing to the Sessions House on the east side of the building, especially as it was asked for.

The design placed second has evidently obtained its position entirely by its plan. It is better lighted than the winning design, and on the whole well arranged. Three areas have had to be resorted to, and being of so small a size would have their disadvantages. The passages are, perhaps, rather narrow for their purposes. The plans, however, throughout show a very careful study and an intimate knowledge of the requirements of a county council.

The third design differs from nearly all the other competitors, by utilising the site right up to the building line all the way along on the west elevation. In nearly every case the centre portion was set back in a recess to obtain light. This plan also is thoroughly well lighted, the large area in the middle very efficiently lighting the corridor all round it and the staircase. A glance suffices to show, however, that in the matter of accessibility to all parts, this design is less convenient than the others The entrance, and therefore the lift, being at the side of the building, lands you on every floor at a considerable distance from nearly all the rooms. The general offices, which should be the most accessible to the lift and staircase, are the least so. On the second floor, with another storey above it, and only one small window to the room, does not appear to be the best position for a sun-printing room. With regard to the elevations of the third design, a low appearance, as in the first, has been properly striven after. Rusticated work has been freely used, the horizontal lines of which, with the assistance of a heavy top cornice surmounted by a mansard roof, prevent the building from looking too high. The centre portion, being recessed behind some well proportioned Ionic columns, would have a good effect. The front façade is more severe than that of the first, and no doubt many would say, therefore, more in character with the purpose of the building.

A very large percentage of the front façade consists of glass window, but as the space is well divided, this might not look so excessive in execution as it does on the drawing. No money certainly is wasted on the other elevations, and this sudden falling off from the front would have had an unpleasant effect from where both elevations would have been visible at the same time, giving rather the appearance of the front elevation having been stuck on.

Of the three premiated designs, the one placed first is, in the writer's opinion, very far ahead of the other two, and the council can congratulate themselves on having obtained an excellent design.

Mr. Frederick Chatterton, A.R.I.B.A., has been appointed assistant lecturer in architecture and building construction at the School of Engineering, Giza, Cairo.

* * *

The formation of a huge Canadian cement combine is announced. Ten large companies are to unite under the title of the Canadian Cement Company, with a capital of thirty-eight million dollars.

* * *

We are informed that Prof. S. P. Thompson, D.Sc., F.R.S., has consented to become first president of the Illuminating Engineering Society, of which the hon. secretary is Mr. L. Gaster, 32, Victoria Street, London, S.W.

* * *

A new type of bridge, over the Pennsylvania Railroad line, in Philadelphia, has its concreted floor suspended from an arch that consists of a steel box girder filled with concrete.

* * *

An alarming accident occurred in Southwark, opposite the large parcels post sorting office in Union Street, part of an empty warehouse collapsing, and at the same time demolishing the backs of several dwelling-houses in Pepper Street. Only one person was injured, and that but silghtly .

Notes on Competitions.

LIST OF COMPETITIONS OPEN.

Deposit for conditions given where known.

DATE OF DELIVERY.	COMPETITION.
Oct. 1.	ABERDARE HOSPITAL. The Aberdare Urban District Council invite competitive designs for a fever hospital for 52 patients, including administrative block, outbuildings, etc. Premiums of £100, £50, and £25 for the designs placed first, second, and third respectively. An Architectural Assessor will be appointed on the nomination of the President of the Royal Institute of British Architects: also a Medical Assessor to act jointly. Particulars and conditions of the competition, together with a plan of the site, may be obtained from T. Phillips, clerk, Town Hall, Aberdare, on deposit of £3 3s.
Oct. 11.	HULL TRAINING COLLEGE for Teachers in Elementary Schools. The Education Committee invites Architects to submit designs. Premiums of £150, £100, and £50 to authors of the designs placed 1st, 2nd, and 3rd respectively. Particulars and plan of site may be obtained of J. T. Riley, Secretary of Education, Albion St., Hull. Deposit, One Guinea, returnable on receipt of *bona fide* design, or the return of particulars within 14 days.
Nov. 30.	HERNE BAY PAVILION ON PIER. Herne Bay Urban District Council invite competitive drawings for a pavilion to be erected on the proposed extension of the pier at a total cost not exceeding £4,000, exclusive of architect's commission. Premiums of twenty-five guineas and ten guineas respectively will be awarded for such two designs as shall be judged of sufficient merit by the Council, and placed by them as first and second; the premium of twenty-five guineas to be afterwards merged into the usual commission payable to the architect, provided the work is carried out by such competitor. Plan of the site and copy of the conditions may be obtained on application to the undersigned on and after the 24th instant on payment of one guinea, which will be returned on receipt of a bona-fide design. Drawings to be deposited at the Clerk's Office, Town Hall, Herne Bay, not later than noon on the 30th November next.—Joseph Jubb, Clerk to the Council, Town Hall, Herne Bay.
Nov. 1.	TECHNICAL SCHOOL. The Corporation of the Borough of Kendal invite architects residing and practising in Westmorland to submit a competitive design, together with a written description and estimate for the erection of a technical school. Premiums of £15, £10, and £5, are offered: the designs to become the property of the Corporation. Particulars may be obtained free from the Borough Surveyor.
Nov. 1.	PRESTON GRAMMAR SCHOOL FOR BOYS. Preston Town Council invite competitive designs and plans from architects practising as principals, for a new grammar school for boys, to be erected in Moor Park Avenue, Preston, and estimates for the same. Premiums of £50, £30, and £20 are offered. The Corporation have appointed a professional assessor. Application to be made to Mr. Alfred Howarth, Town Clerk, Town Hall, Preston, and designs and plans must be sent in by 10 a.m. on Nov. 1.
Jan. 31, 1910.	NATIONAL MUSEUM OF WALES. The Council desires to receive competitive designs for the erection of a new National Museum at Cardiff, Three premiums are offered of £200, £150, and £100, for second, third, and fourth. The Council have appointed Sir Aston Webb, R.A., Mr. John J. Burnet A.R.S.A., and Mr. Edwin T. Hall, F.R.I.B.A., as Assessors. Particulars and plans of the site will be supplied to competitors on payment of a fee of £2 2s., which will be returned on receipt of a design in accordance with the conditions, or if all papers are returned within 14 days. Inquiries to be addressed to Dr. Wm. Evans. Hoyle. Director of the Museums, City Hall, Cardiff.

Grimsby Town Hall Extension.

Sir Alfred Gelder, F.R.I.B.A., the assessor in the competition, has submitted to the Finance Committee of Grimsby Town Council his report upon the fifty-one sets of plans received for carrying the extensions into effect at a cost of £26,000. Three premiums were offered, the first of £250, the second of £150, and the third of £100. Sir Alfred, in his report, said that the task set the competitors in having to adapt the present building was harder than in having to create an entirely new building. The competitors on the whole had done excellently, and, while some had exceeded the cost stipulated, the majority had kept close to the figure and endeavoured to provide the accommodation required at the price named. He personally held the opinion that the accommodation asked for was too much for the price allowed. Having regard to all these points, he awarded the prizes in the following order:—1st, Set No. 18; 2nd, Set No. 44; 3rd, Set No. 47. The Borough Surveyor then opened the sealed envelopes, and the successful competitors were announced as—1st, Messrs. Eade, Johns, and Browne, Ipswich; 2nd, Messrs. Withers and Meredith, 50, Cannon Street, London; 3rd, Messrs. Rigby, Oliver, and Phipps, Market Street, Manchester. With regard to the third set of plans, Mr. Atkinson pointed out that the estimate was £30,207, with a further £3,179 if the tower shown in the designs were decided upon. As the figure given in the conditions was £26,000, he (Mr. Atkinson) would like to know if the set of plans really complied with the conditions. The Borough Engineer said that a margin of 10 per cent. was allowed on the £26,000, and, of course, the third set were outside that limit. The estimate for the first set was £26,657, and the second £27,566. The committee decided to accept the sets awarded the first and second premiums, and referred the third set back to Sir Alfred Gelder, to ask his advice regarding the compatibility of the estimate with the conditions.

Stoke Town Hall.

It is stated in the local Press that at a meeting of Stoke Town Council it was suggested that Messrs. Wallis and Bowden, architects, 33, Old Queen Street, Westminster, should be asked to prepare plans to come within the stipulated sum of £25,000. It is further stated that the Council had decided to interview Messrs. Wallis and Bowden, who were among the competitors, and whose design was regarded as most nearly approaching the council's requirements.

Middlesbrough Library.

At a meeting of the Middlesbrough Free Library Committee, held on September 9th, Mr. J. S. Calvert presiding, the Librarian (Mr. Baker Hudson) reported that, after consultation with the chairman, he had consulted Messrs. Russell and Cooper, London, respecting suggested modifications in the plans for the new library. As a result, Mr. Russell was present that day with the plans for the committee's approval. Councillor W. G. Roberts thought that the modifications shown in the plans before them were without a single exception a decided improvement, and would facilitate the working of the library. The plans were handed round and examined in detail by those present, Mr. Russell explaining them where necessary. Councillor Roberts moved that the alterations be approved, and that the architects be instructed to carry out the plans on the lines indicated as speedily as possible. This was seconded and adopted. The committee agreed to the recommendation that Messrs. Watson and Webster, of London, should be appointed quantity surveyors. In reply to the chairman, Mr. Russell expressed the opinion that the building could be completed in 18 months' time. He thought it would be about the end of October before they would be ready for inviting tenders. It was agreed that the architects should report to the committee when they were ready for tendering.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

Flexure. It is strange to note the confusion of ideas which seems to exist in the minds of many students of steel and concrete construction as to what really is the nature of the stresses in structures, and the manner in which these can be resisted. No doubt this confusion arises in great part because the works of the authors of the special text-books are not at all clear in their own minds about such matters, and even when they are, ambiguity of expression obscures their meaning. No doubt the loose use of words to express several meanings, and indeed to serve a purpose for which they were never intended, is responsible for some of this understanding. We are not here concerned with the pedantic insistence on purity of language. We simply wish to point out how easily confusion of thought might lead to erroneous deduction. For instance, we talk about beam action. Well, we can have beam action in a cantilever and in an arch, if by beam action is meant resistance to bending stresses, but when using the word "beam" we ought to confine it not to any-beam, but to a beam which extends directly thing which has to resist flexure, like a between two supports only. We find the confusion about beam action still greater in connection with floor slabs, which are often spoken of as having beam action in them. It is only so if a slab is supported on two edges, but as soon as it is supported on three or four edges it becomes a plate, and should be spoken of as such. A cantilever really can in no sense be called a beam. An arch and a column still further diverge from beam action. All these constructive elements, however, are called upon to resist flexure or bending, and when beam action is spoken of flexure is really meant, and authors ought to say so. We sometimes hear discussions about continuous beams, and people talk about the cantilever action over the supports. There is nothing of the sort in a continuous beam. It acts as a beam and not as a cantilever. It is quite possible to construct a line of cantilevers sustaining beams, the divisions being placed just where the points of contraflexure occur in continuous beams, and under distributed loading the bending moment will be the same as the truly continuous beam, over the same supports, or a beam completely fixed at the ends has the same bending moment as a bracket sustaining beams, where the points of division are situated at the same distance as the points of contraflexure in the beams. The continuous beam, however, has no cantilever action, properly speaking, as in practice the stresses are very different; the bending moment is simply reversed in sign over the support, and the continuity results in unequal loading on one span, causing stresses that are often indeterminate to be produced in other spans, whereas with a cantilever, which may or may not be discontinuous, unequal loading is not carried to the same extent to the other spans, and the stresses are determinate. Though cantilevers are easily constructed with pin joints or with complete severance of the beam from the cantilever, the former being supported upon the latter, or suspended from the latter, it is not necessary that a cantilever should be so constructed. All that is necessary is to arrange the parts to resist the stresses which would arise in a structure designed with these assumptions. We can, in designing work, make any reasonable assumptions as regards whether we shall make our members in the form of beams, arches, cantilevers, or plates, and if we construct them in accordance with any one of these assumptions, then they will act in that way, unless, of course, they are constructed as to more easily act in some other fashion.

Floor Slabs. In regard to this latter aspect of the subject we may, for instance, refer to reinforced concrete floor slabs. These we often construct to act as beams or as plates, and we reinforced them to resist flexure, but, in providing sufficient steel for this purpose, and in making the slabs continuous over the supports, we may so arrange the reinforcement, and provide such an amount of steel that, instead of their acting in this way, they act as cantilevers and suspended plates or beams. Or, again, if the surrounding beams and neighbouring slabs give such rigid abutment that the slab cannot give and act as a beam, and if we provide sufficient thickness in the centre, then the slab will act as a flat dome, in which case the amount of reinforcement can be very considerably reduced and the arrangement altered.

Arched Roof Principals. There have been several examples recently where arched roof principals have been built in reinforced concrete, and though these have the form of an arch they really do not act as such. They are so reinforced as to act as curved beams, and there is no thrust such as there would be in an arch. They can be more strictly termed curved ribs, and are allied to the steel rib. We find, too, bridges of an arched form constructed with pivots, but here again the principle of construction is not the same as the disjointed masonry arch, and the arched ribs are called upon to resist a bending moment as well as a thrust. In reinforced concrete arched ribs, however, usually no pin joints are provided, and the reactions are vertical. In some cases we can analyse the roof truss more easily as a curved beam resting upon stanchions, which it loads eccentrically. In other cases, however, we can only analyse the structure as a curved beam, the side portions not then serving as eccentrically loaded stanchions, but as the portions of the beam near the support. Now, in such a design the amount of steel that is necessary, and the form and shape of the rib, is very different from what would be required were the truss a true arch. In a true arch the thrust is not vertical at the supports, and the arch requires an abutment or tie at the feet, or springings. The smallest section then occurs at the centre of the span, whereas in a curved beam the greatest depth is there situated. With a true arch much less steel is required, but the thrust at the abutments may be objectionable, and consequently it may be preferable to treat it as an arched rib. Then, again, if the assumption is that the rib is to act partly as an eccentrically loaded stanchion, and partly as a curved beam resting thereon, then the amount of reinforcement will again vary.

The Outward Form. We see, therefore, that the outward form, though much the same, is really no criterion of the manner in which the constructive member will act. We may treat it in several ways, and whichever way we treat it we shall be correct, and the structure will act in that way, if it cannot better act in some other way. The student usually assumes that because a member is of a certain form it must act only in the way which, as he learns from his books, it is customary to assume such forms to act. This, perhaps, is the reason why we find such surprise expressed at the rather novel method of construction employed by reinforced concrete engineers. It often is a matter for wonderment how reinforced concrete arched trusses stand without giving any thrust at the abutments. Then again, a bridge that has been calculated as part cantilever and part girder, but the intrados curved, is also thought to have an arched action, and viewed from this standpoint surprise is expressed that reinforcements are not so disposed.

Architectural Treatment of Reinforced Concrete. We see, therefore, that the form in a reinforced concrete structure, and also in steel work, must not be judged by ideas associated with masonry or brickwork constructions, nor, indeed, with timber. Architects, as a rule, view all matters from these points of view, as they have been trained to study examples of construction carried out many years ago, and they therefore think that constructive members having the same form as these earlier examples must act in the same way. They should bear in mind, however, that we are nowadays using two very, very different materials, viz., concrete and steel, which have resulted in complete departures in methods of construction. Eventually the architectural profession, and perhaps in time the public, will get to realise instinctively the difference in the types of construction though they bear the same outward form. At present the appearance of reinforced concrete and steel work is judged by canons of taste derived from other methods of construction, and to the eye which has been trained instinctively or by education to recognise and appreciate the structure of those forms built up in the past on other methods and with other materials, steel work and reinforced concrete naturally appear ungainly and inartistic; but when the profession begin to realise the logic of their forms, and gets instinctively and educationally to appreciate their true structure, then they will come to realise that beauty in architecture springs from constructional fitness, and not from any machine applied scenic canons. The styles are derived from an architecture of stone, and if we apply them to an architecture of any other material then they can only satisfy the eye by an imitation of stone, or by the suggestion that they are stone. Looked at from any other point of view they are absolutely illogical, and when this is realised they become foolish and indeed ugly. There is, of course, the general form and outline—the play of curved line against straight line, and symmetry and proportion of mass to be considered in an architectural problem, but these are other matters outside the foregoing argument. The architect, of course, should study such general features, but when he has gone so far then the other details should be left to work themselves out. It will, no doubt, be a good many years before we are able to deal thoroughly satisfactorily with the newer architecture of steel and reinforced concrete, but by a frank acceptance of the construction we shall arrive at a modern architecture much sooner and with far greater promise of success.

Cantilevers. We are, however, able to do weird things with steel and reinforced concrete, such as extending balconies and supporting almost whole buildings upon cantilevers; hanging compartments, too, in mid air, by suspending them from beams overhead. These are objectionable features because, as a rule, they spring from some commercial requirement that is not truly logical, the outcome, perhaps, of some desire to arrive at a certain result by some roundabout method, because other things prevent a straightforward and truly economical solution of the problem. But it is unfair to use such instances to support a contention that materials and methods of construction that permit such things to be done easily are therefore bad and inartistic; they only serve as examples to show how dependent we are upon the fitness of every portion of the structure in order to obtain architecture. The architect who is called upon to design a structure which is out of place, or required to serve some purpose which is not a true need of the community cannot expect to make a truly architectonic structure. He may make it scenic, he may make it pretty, but it is not architecture. Then again, certain buildings which have to serve a lower commercial use can obviously never rank so high in the architectural scale as structures which serve a higher purpose. For instance, a warehouse can never rank with a cathedral, though the one may be as fit for its purpose as the other, no more than a humble flower can compare with a higher form of vegetation, but each should be beautiful in its way, and such beauty is only obtained by fitness. We are fortunate to-day to have these facts better recognised by architects, and an attempt is being made by the architectural profession in reinforced concrete and steel work to apply these new materials and methods in a more logical manner. Several architects have called attention to the fact that in reinforced concrete we have a method of construction which is different from that which has preceded it in the history of any past age of building, and embodies principles which are entirely revolutionary in character.

The Architect's Chance.

We therefore see that the modern architect has given to his hand the chance to arrive at an architecture which shall be entirely different from any that has preceded it, and which can be as fine and as noble as the architecture of Greece, Egypt, or Rome, or, indeed, of the Gothic period. To the engineer reinforced concrete is extremely interesting, because of the many problems it provides for solution. The design of structures in reinforced concrete is much more difficult and intricate than steel work, and if the latter has provided many interesting features and novel constructions, reinforced concrete promises still more. To the architect also reinforced concrete in its way is quite as interesting as to the engineer, for in studying it the architect can feel that he has a chance of doing work that shall compare favourably with the work of past generations of architects, and in employing it there is no reason why there should not be as much enthusiasm and as much interest displayed as was doubtless to be found among the architects of Greece and the architects of the Middle Ages, when inventing and employing their methods of building and devising forms which should express the function of their structures.

French Reinforced Concrete Designs.

There is one feature in respect of the design of reinforced concrete structures made by French engineers which must surely have struck anyone who has studied published designs, that is, the remarkable ingenuity displayed, and the novelty and invention. Engineers in France (and, indeed, in Germany) are educated much more thoroughly than they are in England in respect to the theory, and though this has its disadvantages in often increasing cost by over elaboration in design, yet it more often results in a much closer analysis of the stresses in structures, and this draws attention to important factors present but often overlooked, and leads to a better understanding of the nature of these stresses. In French work it will generally be noticed that structures are designed with an interlacing network of ribs and beams, modelled on the lines of timber or stone structures, just as the fancy seemed to strike the designer. In some cases these forms have been arrived at by reference to the results of practical experience in connection with structures built with other materials. In other cases they have been arrived at by a process of very elaborate analysis. After the structures have been built they have, fortunately, been carefully tested, and the facts recorded, so that we know how far the designer's theories have conformed to fact. This elaboration in England would undoubtedly greatly increase the cost of structures, for the workmen here do not take so great an interest in such work as they do in France. The French mechanic of the superior class is to be relied upon, and he seems to like novel work. The result is that though the work may be very elaborate, in many cases the cost is not so greatly increased as one would suppose. Though there are many contractors in France who appreciate the advantages of simplicity in respect to economy, we think that in America and in England contractors study this aspect of the work more than is done in France or Germany.

Centering for Reinforced Concrete.

Economical methods of carrying out reinforced concrete have now been worked out in considerable detail as regards the design of the structural members, and economical methods of disposing the steelwork and manufacturing the same. The handling of the concrete by means of mechanical mixers and electric hoists has reached a point at which we can see that there is not much more saving to be effected in execution. There is, however, one element in which we can clearly see that economy is possible, and that is in respect of centering. There is, indeed, an enormous waste of material and labour in the erection and re-erection of timber centering. We use timber because it is at present the most economical material, but a light form of metal sheeting would stand much more wear and tear, and it would be hardly any heavier to handle. The nature of practical work, however, differs so from job to job that standardised centering cannot be used generally. In England, at any rate, it is seldom that we have a building planned out on such regular lines that the floors can be repeated over and over again, and the centering used many times over; therefore, to use a standard form of centering we should have to find one which would be capable of modification to suit varying circumstances that occur in practice, or we could use it perhaps advantageously for parts of structures which conform to some sort of general standardised form, though we can see possibilities of economy in this respect.

The Commercial Aspect.

The fact, however, that we pay more attention to the commercial aspect of the subject is to be regretted, because, in a science such as reinforced concrete, which has only grown up within the last few years, and is still to a great extent in its infancy, there is any amount of room for experience, and we can learn much from these ingenious methods employed in France. There are often two or three ways of getting at a result, any one of which is hardly any more costly than another in the end, and the benefit of trying all these varying methods of getting at one result is that we may discover points in every method that can be advantageously combined with points from another method in future jobs. Most remarkable results have been obtained by French contractors; they have shown us wonderful resistance in buildings by extraordinary tests. Much information has been gleaned from these tests, but it is surprising that though these structures have been designed from a theoretical point of view, yet, when it comes to analysing the results of these tests, the matter is often regarded more from a practical point of view. Of course, the analysis of full-sized tests of building structures is very difficult to conduct, and requires very great scientific ability, but there are many engineers in France who are thoroughly competent to undertake such research, and therefore, though we can well understand the practical contractors not being able to find sufficient time, or perhaps to display sufficient theoretical ability, to analyse the results completely themselves, we are rather surprised that they do not engage the theoretical talent, or that the professors of schools and colleges do not themselves undertake the work of analysis. There have been a few professors in France who have done this, and have furnished us with an immense amount of information which has been most valuable and improved our general knowledge of the science of construction in reinforced concrete. As, however, we are unable to have provided for us always a close analysis by French engineers of the work of their own constructors, it is important that engineers in this country and elsewhere who have the time and opportunity should study closely the work of constructors in France, and also, it may be said, in Germany and Austria, who employ novel methods in preference to standardising the practice such as seems to be the tendency in this country and in the United States, for it seems evident that by a close study of these somewhat experimental works we should obtain much information that would advance the practice and theory of reinforced concrete and of structural design generally.

Metal Centering.

Unfortunately, up to the present, no standard metal centering has been devised that is capable of general adoption. Some attempt has been made to improve the method of centering in timber, but not very successfully. There is no doubt the need will lead to something satisfactory being discovered shortly. Whatever form of metal centering is eventually invented, it will have to be of such a nature as to be adaptable to many variations in practice; for instance, if it is to be used for floor slabs it must be possible to vary the size and shape of the floor slab considerably. Then, as regards the beam boxes, not only must the width vary, but the depth also. It is possible, perhaps, on some jobs to keep the beams of fairly uniform width, but the depth would certainly have to vary. This need not create much trouble, because one can easily shift the bottom board or support up or down within the sides of the box. Then, for columns, the centering should be capable of being varied very considerably, not only as regards heights, but as regards the width of the sides of the columns. Some form of very thin sheet iron or tin plate appears to be the most promising material from which to construct such standard centering, and it would be possible to stiffen it by means of securely attached angles or tees, or one could employ timber struts to support it, arranged some distance apart in contra-distinction to placing them closely together as with timber centering. There have been a few sheet iron centerings introduced, but they very often consist of curved sheets which are objectionable because they give a curved socket to concrete floors. In other cases the metal sheeting has been left in position to form a permanent centering. This, though it is not so extravagant as might be thought, has its objections, because it is liable to rusting and is unsightly unless covered up, and if the latter is done, the cost is increased to a prohibitive figure. There is plenty of scope for ingenuity in the invention and devising of such standardised centering, and we hope that before very long it will be possible to reduce the cost of erecting structures of reinforced concrete by the adoption of such improved methods. Having now advanced sufficiently far to be able to effect very great economy in all other directions, namely, in designing and the executing of the practical concrete work, it only remains to economise in the centering to still further reduce the cost of reinforced concrete, and bring it into increasing use.

REINFORCED CONCRETE PILES.

(Continued from page 133, No. 758.)

Belonging to the first division of moulded reinforced concrete piles is the "Chenoweth," but this pile is not exactly moulded in the ordinary sense, namely, by being cast in a box. The pile is round, and is made without forms or boxing on a special apparatus. Its form is shown in Fig. 1. It has a steel pipe or rod in the centre to which is attached by means of small rivets driven into holes slightly smaller a sheet of ordinary black wire fabric of No. 16 U.S. gauge, with ½in. mesh, of the length required to make the pile. The other edge of the sheet is attached to a movable platform which is pulled towards the core as it is wound up. On this sheet is placed the other reinforcement, consisting of longitudinal bars, and the whole is covered with a layer of fine concrete. The mass is then wound up by means of an apparatus consisting of a travelling platform to which the sheet is attached by one edge and a roller; the pile is formed thus, the winding pipe or rod in the centre is set in line with the shaft of a large spur wheel, the pipe or rod in the centre is rotated, and the netting and its covering of concrete is wound or coiled up, while, at the same time and as fast as the netting and concrete are coiled up, the platform moves under the roll, and the roll itself rotates. The forming cylinder of concrete is by this means kept under constant and heavy pressure between the platform and the roller. The roll of concrete is bound by wires placed round it at close intervals and tied, these wires being contained on spools arranged between the moving platform spaced every six inches along the pile and fastened to the wire mesh, so that when the pile reaches the lower edge of the platform it can be revolved about the axis, causing the wire to be wound on the pile. In this manner the wire is passed around the pile a number of times and secured. At the driving end of the pile the spools are placed 4in. apart for the first 6ft. of the pile, and then 6in. apart for the remainder of its length. In some cases another method of fastening the other edge of the wire cloth has been adopted, namely, to substitute for the wire ties rivets with their ends upset, so that they are of slightly larger diameter than the mesh of the cloth. These rivets are inserted in the outer edge of the cloth with these upset ends upwards, and as the piles are rolled up they are forced into the meshes of the fabric into the body of the pile, thus buttoning it together, as it were. When the pile has been thus formed it is rolled still further on the inclined platform, so that without any lifting the completed pile is rolled therefrom to the truck which is to carry it to the seasoning yard. The platform of the truck is also inclined, and when the car has reached the yard the pile is rolled to its place. By this method no large plant except the rolling device is required to handle the pile during its moulding stage. The concrete used in forming these piles is generally proportioned 1 : 2 : 3. As regards the means of driving these piles into place, a driving head is usually favoured, and when sinking by means of a water jet is resorted to, the core consists of the pipe above referred to down which water is passed. Fig. 2 shows the form of driving cap which is being used with these circular piles, but its form can be modified to serve for other sections of pile. It will be seen that the cap has side flanges to travel in the guides. The Chenoweth pile has been constructed up to 61ft. in length, and these piles after having been driven have been pulled out for examination and found to be intact, and redriven. Like other reinforced concrete piles, they appear to stand very severe treatment. In one instance an attempt was made to destroy a pile by over-driving; when it was pulled up for examination the only apparent injury was the mashing or brooming of the upper two feet of the butt end. Another moulded pile is that shown in Fig. 3, and made by the British Reinforced Concrete Engineering Company, Ltd., of 196, Deansgate, Manchester. In this design special patented binders that keep the rods in place and have ends extending to the centre of the post to reinforce the core are used, and increase the strength.

A special patent reinforced concrete pile that has been used for the foundations of some of the tall buildings in New York is constructed as follows :—

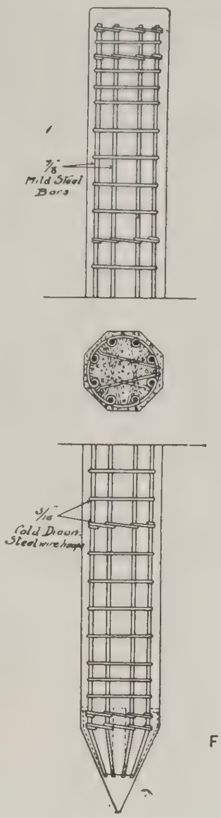

FIG. 3.—THE BRITISH REINFORCED CONCRETE ENGINEERING CO.'S PILE.

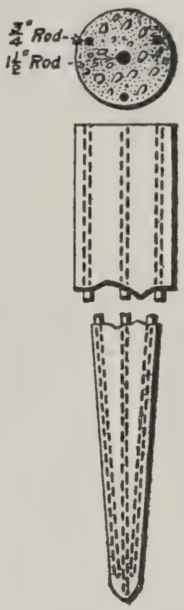

FIG. 4.—RAYMOND PILE.

A shell of sheet steel of about ⅜ins. in thickness, and 12ins. in external diameter is coupled together in sections, these being joined by inside couplings. Within the shell reinforcing rods are inserted in sections, and are fastened together by a special mechanical device, so as to form practically a continuous rod. The shell is sunk first in the manner described for the foregoing piles that are cast *in situ*, but the means of driving is to use a pneumatic hammer together with a water jet. After the pile has been driven the earthy material within the shell is withdrawn and replaced by concrete in a similar manner to that previously described in connection with the other piles of this class. This particular pile has a large area of steel in its cross section, and in consequence the Building Department of New York City gives it a higher bearing value than any other, viz., 350 pounds per square inch on the concrete in compression, and 4,200 pounds per sq. in. on the steel. The life of the steel in the exterior shell is doubtful, as not only ground water may corrode the pile, but also any gas in the subsoil or stray electric currents may cause corrosion by electrolysis.

Up to the present we have only dealt with the forms of piles which are cast in a mould, and driven very much in the same manner as a timber pile. There is another type of pile which is formed *in situ*. In 1901, Mr. A. A. Raymond, of Omaha, invented this new form of pile. Briefly described, the Raymond system was to drive a tapering sheet steel shell or pipe to refusal by means of a collapsible steel core, and then to withdraw the core and fill in the shell with concrete. The sheath is expanded by means of a wedge driven at the centre, as shown in Fig. 5. When it is desired to withdraw the sheath, the wedge is pulled upwards so as to allow the core to collapse sufficiently to allow it to be withdrawn from the shell. The Raymond pile is tapering in shape. The steel shell prevents the earthy material from mixing with the concrete, this shell being left permanently in position. For driving the sheath, a heavy pile driver, usually mounted on a turn-table frame for facility of operation, is used. The core or sheath weighs about three tons. Before beginning operations the core is suspended in leads, with the point about 8ft. above the ground, to allow clearance for the section of casing to be slipped on. The casing is made from sheets of No. 20 U.S. gauge metal, 8ft. long, which are formed into the required shape, the edges being bent to connect together and retain the shape of a truncated cone. These are of various sizes to fit the tapering core, and are slipped on in regular order, with a considerable overlap to each section, enough sections being used to cover the core completely to the length required. Occasionally a joint between the sections is covered with an extra section, to make it tighter. When this is done, a pressed steel butt or thimble is forced on the point of the core, overlapping the last section of casing. The core is now ready for driving. It is slung back into the leads, lowered carefully to the proper location on the ground, and is then driven to refusal by a steam hammer weighing about three tons. When a core has been driven to the desired depth, it is collapsed and withdrawn, and the steel casing in the ground is immediately filled with concrete, proportioned, as a rule, about 1 part Portland cement, 2 parts sand, and 4 parts broken stone or gravel. The concrete cannot be put in place until the core has been withdrawn.

In practice it has been found that the shell, being made up of sections, is not tight, and water and quicksand enter. These have to be syphoned out before the concrete can be put in place. Sometimes it has been found that where the shells have been subjected to great hydrostatic pressure, the casing has sometimes collapsed and has had to be redriven. In other cases where hard driving into boulder formation has been resorted to the core has been so severely injured as to be put out of commission, and has had to be replaced. The pile tapers from 20ins. at the butt to 8ins. at the point, and it is claimed that its tapering shape distributes the load throughout the entire length of the pile, and compresses the soil to such an extent that the full bearing of the upper layers is utilised, while, also, the metal casing prevents the soil from mixing with and weakening the concrete.

In 1903, Mr. Shuman, at Philadelphia, invented a pile formed by a somewhat similar method, viz., in regard to its being made in place, but the details are very different. This pile is known as the "Simplex." In this case a hollow steel pipe, three-quarters of an inch in thickness of shell, and 16 ins. outside diameter, and of the same diameter throughout its length, is provided at the lower end with a special alligator jaw or shoe, which is closed during driving in order to prevent the entrance of the surrounding materials into the pipe. The jaw is securely attached to the pipe form by cable hinges, and is used over and over again. It is composed of two symmetrical wedge-shaped parts, which are kept closed during the operation of driving by the pressure of the earth. In harder soils, a detachable cast iron point is often used, but this is more expensive than the jaw point, as it has to be left permanently in place, and one point has to be supplied for each pile. The upper end of the pipe form is strengthened by a strong band of steel shrunk into place and firmly secured with countersunk rivets. This steel band also serves as a shoulder for the clamps which are attached to the piling device for withdrawing the pipe. A steel-driving head, sliding under the leads, with a circular projection on its lower face to fit into the top of the pipe form is lowered on to the form, and not only serves to hold the top of the form firmly in place during driving, but also receives the impact of the hammer, from which it is protected by a rope mat. The form is driven by an extra heavily built pile driver, which, in addition to the usual equipment, has a strong pulling device attached to the leads for the purpose of withdrawing the form after driving. When the pipe form has been driven to refusal, the driving head is hooked to the hammer by a wire attachment, and both are hauled to the top of the leads and attached there during concreting operations. A charge of concrete, consisting of about five cubic ft. is dropped into the form, after which the entire form is raised about a ft. by means of the pulling device. Then a heavy iron rammer is dropped on the mass, and by its impact opens the jaws and forces the concrete out into the space made by the end of the form. This procedure is repeated until the form has been entirely withdrawn from the ground and the space it occupies is completely filled with concrete, which hardens in place and becomes a concrete pile. This method of filling is varied to meet varying conditions. Occasionally, after the jaw has been opened, a sufficient quantity of concrete to make a complete pile is placed in the form, and the latter is steadily withdrawn. This plan, under certain conditions of the soil, gives a better shaped pile, because, under the first method, the jaws have a tendency to close partly, on account of the excess of pressure at the top of the form, thus making a pile of irregular section. This is avoided by giving a regular and steady movement to the pipe form.

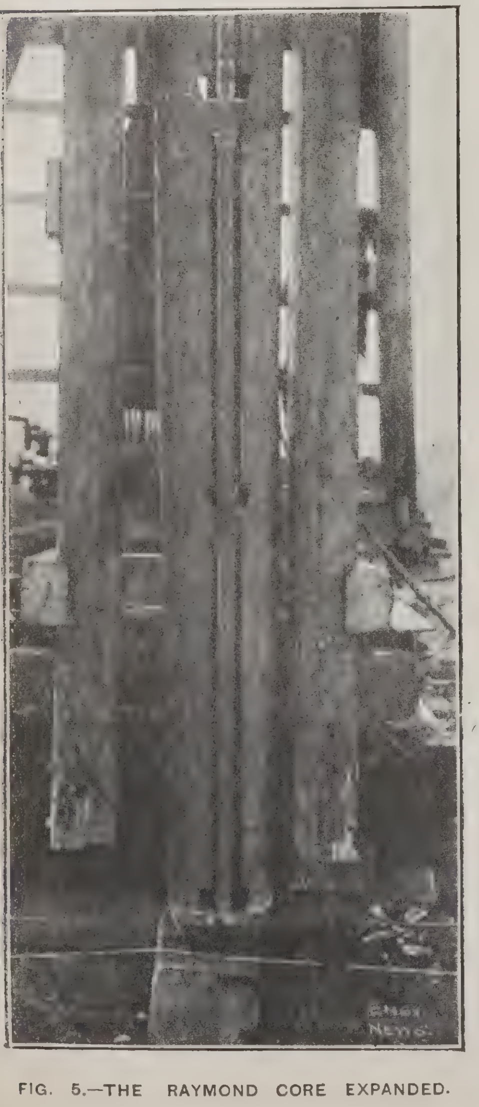

FIG. 5.—THE RAYMOND CORE EXPANDED.

A 1:2:4 mixture of concrete is usually employed, and the mixture is quite wet. When placed within the form in mass it is heavier than the surrounding soil, and thus it is more than able to balance the pressure, and the soil has no tendency to cut off any section of the pile, as the excess pressure serves to force the concrete into the soil. It has been found that with very hard driving, heavy forms, even with ¾in. shell, have been buckled at the top. It should be noted here that if a form of this nature is so injured, a timber pile in the same circumstances could never be driven, but would simply buckle up when a very short distance in the ground. In another case, where Simplex piles were used, a form was driven into the lower stratum so firmly that the pulling device could not withdraw it, so it had to be filled with concrete and left permanently in place. It is claimed for piles of this type that the fresh concrete which comes into direct contact with the surrounding soil, enters into all its irregularities and unites with it, thus forming a rough exterior surface which gives the pile a large amount of frictional resistance, while, further, as practically all the resistance to driving is confined to the point, the greater amount of the compression takes place where the pile needs it most in order to transfer its load as a column. A modification has had to be made in soils which were of a fluid or semi-fluid nature, as in that case the soil has not sufficient consistency to serve as a mould to retain the concrete in place. In one such case, after the driving form had passed through the soft strata and had driven to refusal into the firm underlying stratum, the initial charge of concrete was inserted and the point forced open; then an auxiliary form of No. 20 U.S. gauge metal, of slightly smaller diameter than the driving form, was dropped into place, and the required reinforcing was adjusted. Then the auxiliary form was completely filled with concrete, and the driving form was withdrawn, leaving the thin shell in position to act as a mould for the concrete. The length of piles of the ordinary type driven by the Simplex system is between 20 and 25ft., but piles up to 45ft. long have been successfully constructed. In both the Raymond and the Simplex piles a reinforcement of rods can be inserted. In the case of the Simplex pile the reinforcement has to be so arranged as to allow the rammer for the concrete to be dropped down, or it is possible to form the pile without the use of the rammer by employing a sloppy concrete which will pass readily down the form, and enter into all the parts of the reinforcement.

Also, in some cases, single rods have been pushed or churned into place through the wet concrete. Rods are usually left with their heads projecting above the concrete one foot or more, in order to assist the bonding of the capping to the piles.

One advantage of "made in place" piles over moulded piles is that as they harden in the place where they are to be used, a small foundation can be completed before the moulded piles would be ready to drive, thus effecting some small saving in time.

In the construction of the foundations of a garage at Albany, N.Y., an unpatented pile of this class was used, which serves to show one of its possible variations. The original surface of the site was a stiff clay, and had been covered to the depth of 15ft. by clay from adjoining excavations. Thus it was necessary to carry some of the load to the original surface. This was accomplished by excavating holes, 10ins. in diameter, through the overlying fill to the original surface, using a screw post-hole digger, and then filling the holes with fresh concrete, the clay filling being stiff enough to retain its position during the operation. The piles were spaced at 3ft. centres, two staggered rows being placed under the walls, while the pier-loads were supported by clusters similarly spaced. The total length of piles was 4,779ft.; the labour of digging the holes cost 20 cents per 1in. ft., and the concrete 7 dollars per cubic yard in place, or about 13 cents per 1in. ft., making a total of 33 cents per 1in. ft. of completed piles. In pile work there is usually quite a large charge for

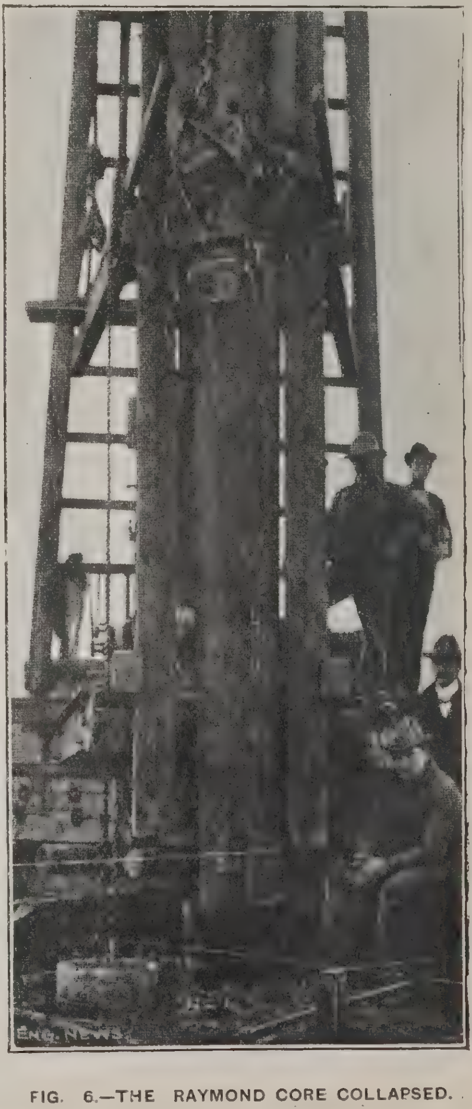

FIG. 6.—THE RAYMOND CORE COLLAPSED.

plant installation and dismantling; but in this instance this was reduced to a minimum, which accounts for the low unit cost. No compression of the pile-hole was made; but the supporting power of the pile was assisted materially by the capping, which acted as a spread footing.

Another type of this class has been used in the clay soils around Boston, Mass., where the clay was overlaid by some 20ft. of sand and silt. Through this an 8-in. casing was forced into the clay and the materials were washed out. Then a chambering device was used to expand the footing of the pile by cutting away the clay, which was also removed by washing. In this way the area of the footing of the pile was made sixteen times as great as that of the pile itself—a very effective method of obtaining a spread footing at considerable depth at a moderate cost. This type of pile has been patented.

Just previous to the construction of the pneumatic foundations of the Trinity-United States Realty Buildings, at Broadway, Cedar Street, and Trinity Place, New York City, the foundations of three columns of the Sixth Avenue Elevated Railroad, located on the kerb-line of the Trinity Place front, were carried to hardpan, 75ft. below the kerb, by using steel-encased concrete piles. This was done in order to avoid any possible settlement of the railroad structure during the sinking of the caissons, which were to be carried to bed-rock. The original piers of these columns were founded on the sand at about ground-water level, 12ft. below the kerb. Below this footing elevation there was a thick stratum of quicksand extending to the hardpan, the latter resting directly on the bed-rock. The transverse girder supported by the first column was shored up, and the column and its pier were removed and then restored completely before any work was done on the next column. Over the close-sheeted excavation made for the removal of the old pier there was used a short pile-driver which could be operated under the overhanging girder, and this was assisted by a water-jet, to force a 12-in. standard, black, wrought-iron pipe, in random-length sections, to the hardpan. When the first section had been worked down to the bottom of the sheeted excavation, another section was joined to it with outside couplings, the threads on the ends of the pipes being cut long enough to allow the ends of the sections to butt properly. The lower end of the bottom section was protected in most cases by an open driving-shoe, which made it easier to sink the pile-shell than with a cone-shaped, closed point, as it allowed the free use of the jet to soften up the material. The upper end of each section was protected from the direct impact of the hammer by a driving-head, which screwed into its coupling and butted on the pipe. This driving-head had a slotted opening in its side through which the jet was worked during the operation of the hammer. Most of the material from the inside of the pipe was removed by the jetting process; any that remained was taken out by an ordinary sand-pump. There was no difficulty in getting out all the material after the pipe had reached the hard-pan, the depth being checked by steel-tape measurements, and the interior of the pipe inspected by the aid of a lantern. The pipe was then filled with 1:2:4 concrete. Five piles were thus placed for each pier, one near each corner, and the fifth in their midst directly beneath the centre of the column. The piles extended 5ft. into the mass of concrete which formed the new pier, and was 8ft. square at the base, and stepped in to meet the column-base at the kerb-level.

A similar pile has been used in the underpinning of buildings in New York City. It is placed directly beneath the well by cutting in the latter a vertical opening, from the starting elevation and through the foundation courses, of sufficient width and depth to leave ample working space around the pipe. The sections are forced into the soil by hydraulic jacks assisted with water-jets, using the remainder of the wall for reaction purposes.

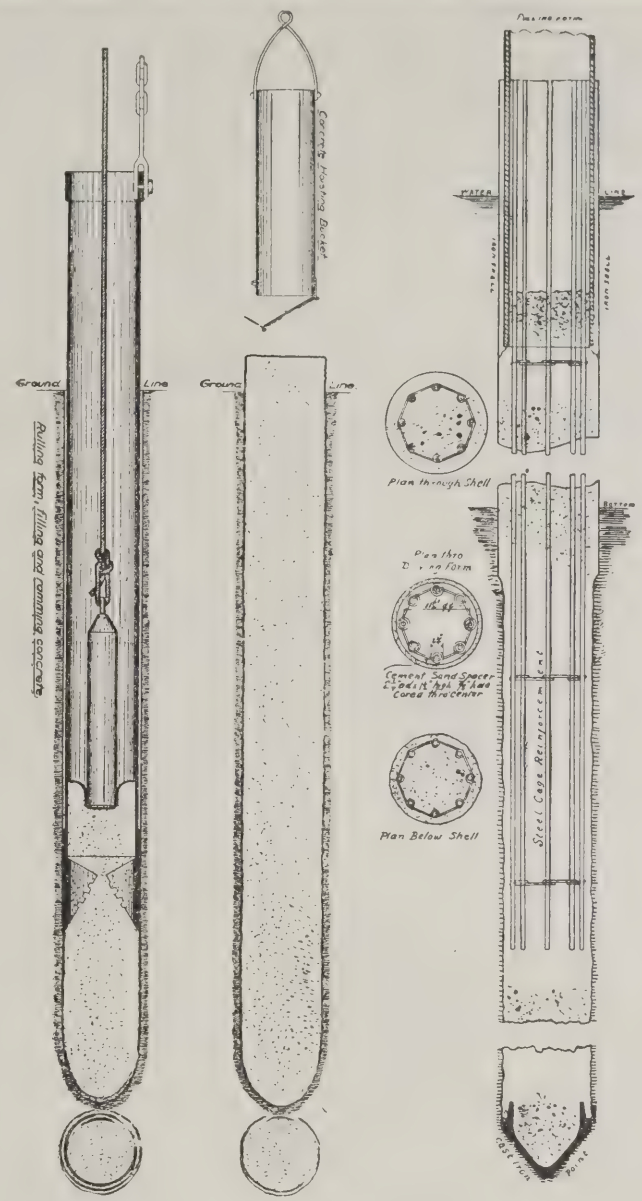

FIG. 7. DETAILS OE THE "SIMPLEX" PILE.

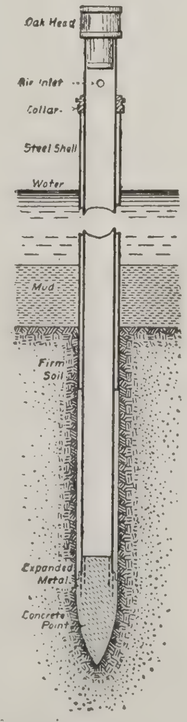

FIG. 8.—THE "SIMPLEX" FORM WITH CONCRETE POINT.

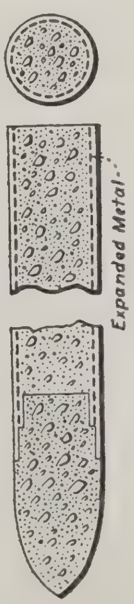

FIG. 9.—THE "SIMPLEX" PILE WITH CONCRETE POINT COMPLETED.

These piles are of various diameters, from 8ins. to 3ft., in proportion to the loads to be carried, and the spaces are cleaned out in a manner similar to that just described, except that the largest sizes, in which there is space enough for a man to work, are cleaned by hand. The spaces are then filled with concrete under air-pressure. When the pile is completed, the load of the building is transferred to it by masonry and wedging-stones. It is the most effective system of underpinning in use to-day, as it gives a positive assurance of the safety of the building, and at the same time does not occupy any space outside the wall; thus the contractor has a lot free from all obstructions.

Before driving piles it is very valuable, indeed, almost necessary, to ascertain in a practical way the bearing power of piles driven into the soil by an examination of the strata. Not only is it impossible to calculate the bearing power of piles without such information, but it is very likely that some modification or variation will be necessary in the form and construction of the pile to give good results. A very careful survey of the subterranean strata should be made by making test borings in various parts of the proposed sites. Though good wash borings are generally considered to furnish sufficient information, core borings are more reliable though somewhat more expensive. Where at all possible, it is most valuable to drive test piles, in which way the approximately correct depth necessary to drive piles can be determined, and the length of pile can therefore be specified; but, unless a pile driver can be obtained on the site, or can easily be placed thereon, such preliminary investigation by driving test piles is very expensive. With a job of any magnitude, however, economy will result in the end. Test borings should show the various strata, their thickness, etc., and the height of the sub-soil water. The strata will be of different thicknesses and height in different parts of the site, and the borings should provide all the information necessary to determine the length of the pile, the type of the pile to be used, and on which sub stratum to place the load.

The concrete pile, as we have stated before, develops a greater carrying capacity than the timber pile. Individual piles have been tested with pig-iron loadings of 45 tons and more without settlement, and piers of five piles have satisfactorily supported a test load of 300 tons, or an average of 60 tons per pile. In practice, however, it seems to be the custom not to load plain concrete to more than 25 tons per pile, but when reinforced to provide for excess loading, greater loads can with safety be carried. Timber piles of a comparable size would not be loaded to more than half of this amount, therefore the carrying capacity of the plain concrete pile is double that of the timber pile. Demonstrating the carrying capacity of concrete piles by means of an actual test loading, consisting in placing a platform on a pile and loading it with pig-iron to double the guaranteed load, and by means of a series of levels noting whether a settlement occurs, is thoroughly practical and satisfactory, but it is of a practical character only. In piling work it is very difficult to arrive at any theoretical rule that is at all satisfactory for general use. It seems to be the custom with those who have to deal much with piling work to solely rely on rule-of-thumb methods, and the results of actual experience in the driving of test piles. Attempts have been made to calculate the supporting power of concrete piles by the formulæ generally used with timber piles, but none of these formulæ seem to apply exactly, and they are still more inappropriate when the concrete pile is jetted into place. When driven into position, Ritter's formula, generally known as the Dutch rule, has been chiefly used The Ritter formula is:—

$$W=\left(\frac{b}{e}\right)\frac{Q^2}{Q+q}+Q+q$$

in which

W=the resistance to further penetration,

Q=the weight of hammer in pounds,

q=the weight of pile in pounds,

h=the height of fall in inches,

e=penetration in inches by the last blow.

This formula, however, only applies to a case where a pile has been driven, it does not help us to determine from the nature of the strata the approximate bearing power of the pile. Furthermore, as most reinforced concrete piles have to be driven with a dolly and cushion, the weight of the blow that comes upon the pile is very much less than that determined from the weight and drop of the hammer. A heavy ram with a short drop is not supposed to shatter the pile so much as a light ram with a long drop, and some of the best results seem to be obtainable with a 4 to 5 ton monkey, and a short drop that is reduced as the pile approaches its final position. In finding a formula to express the bearing power of a pile, many factors enter which are very difficult of determination, and also some which in practice will materially alter theory. For instance, the general assumption is that a small pile will go in easier than a large pile, but this is not true in the case of timber piles always, for the effect of the blow depends on the rigidity of the pile, thus a large pile is more rigid than a small pile, and consequently with the same weight of ram and the same length of drop a large pile will often penetrate much quicker than a small pile. Then there is the question of the friction of the pile against the ground. When piles are driven quickly the friction seems to be greatly overcome, and the pile will go in much easier and quicker than when the blows are not delivered so close upon each other. The penetration, therefore, under such quick driving, is more than can be obtained if the piles are allowed to rest for a time; the soil then sets round the pile and seems to grip it, so that a pile which showed considerable penetration at the last blow would, if allowed to remain for some time, not show any movement, or very little movement, under the same blow. Then, a rough pile will come to rest sooner than a smooth pile, and a pile that is out of the "true" also comes to rest sooner than a "true" pile. Again, a pile with a blunt shoe or without a shoe altogether, will also come to rest sooner than one with a sharp shoe. Square piles seem to penetrate easier than round piles in harder soils. To determine formula it has been suggested that to measure the skin friction the force required to withdraw the pile should be ascertained, but this, though it appears to be a useful suggestion at first sight, is really very inconclusive, because tests have shown that much greater force is required to withdraw a pile than to drive it. Another point of complication is the calculation of the resistance of a pile which is driven through a soft stratum into a hard one. The portion of the pile in the soft stratum acts as a long column unsupported, or at least slightly supported. Therefore lateral flexure has to be considered, and this induces shear stresses. These are also developed when the piles are united at the top by a decking, as in the case of a pier and vessels ride against that pier, applying impact stresses to the side of the piles and causing them to act as beams fixed at the ends. In other cases, too, piles have been used, as, for instance, at works in Southampton, to sustain retaining walls, and the pressure against these tends to shear the wall and its foundation from the piles.

Considerable controversy has occurred respecting the merits of tapering piles versus straight piles. A tapering pile depends for its bearing power more on its shape and the skin friction thus developed than on its efficiency as a column, while a straight pile depends on the skin friction developed by its exterior surface and also on its strength as a column. As we have said, the amount of skin friction developed by any pile depends not only on the character of the surface, but also, we can add, upon the area of that surface.

Supposing we consider for the moment only the area. Taking two piles of equal length and having butts of the same size, one tapering to 6ins. at the point, while the other is straight throughout, it will be found that the straight pile has a larger surface area on which to rely for skin friction, and has a larger bearing surface at the point. Supposing, for instance, these piles measure each 14ins. at the butt, and are 20ft. long, the tapering pile will have a surface area of 52.4 sq. ft., as compared with 73.3 sq. ft. for the straight pile. The point area, too, of the tapering pile will be .2 sq. ft., while that of the straight pile is 1.07, the latter having almost 5½ times as much area available to transmit its load as a column, about 1.4 times as much superficial area, and 1.7 times as much volume, which also represents its displacement, the volume of the straight pile being 21.4 c. ft., while that of a tapering pile is only 12.6 c. ft. The table shows a further comparison that is instructive as regards the relative frictional values of the upper and lower parts. It will be seen that a tapering pile has a much larger proportion of its surface area in the upper than in the lower zone, which indicates that it must depend on the upper layers of the ground for the greater part of its supporting power, while the straight pile has its surface area uniformly distributed, and can utilise all the strata through which it passes. Thus it will be seen that 32.5 per cent. of the surface of the tapering pile is in the upper quarter, while only 17.5 per cent. is in the lower quarter. Supposing we take the safe load on firm gravel or clay to be 10 tons per sq. ft., and we assume that each pile is called upon to sustain a load of 20 tons, and that each has been driven to the firm gravel so that it can act as a column, then the tapering pile with only 2 sq. ft. of area at the point can only transmit as a column 2 tons, leaving the remainder of the load—18 tons—to be supported by skin friction, and about one-third of this would have to be supported by the upper strata. The straight pile, having 1.07 sq. ft. of area at the point, can sustain as a column 10.7 tons, leaving only 9.3 tons to be carried by skin friction, and about one-fourth of this, or two and one-third tons, would be supported by the upper strata, as against about six tons with a tapering pile. Where there is any likelihood of a scour on the bottom into which piles are driven, the tapering pile is at a still further disadvantage, for the scour of the current takes place at the top, at which point the tapering pile, as shown, concentrates so much of its resistance. Piles in such circumstances should be driven to firm bearing strata, and not reply on upper strata to support the load.

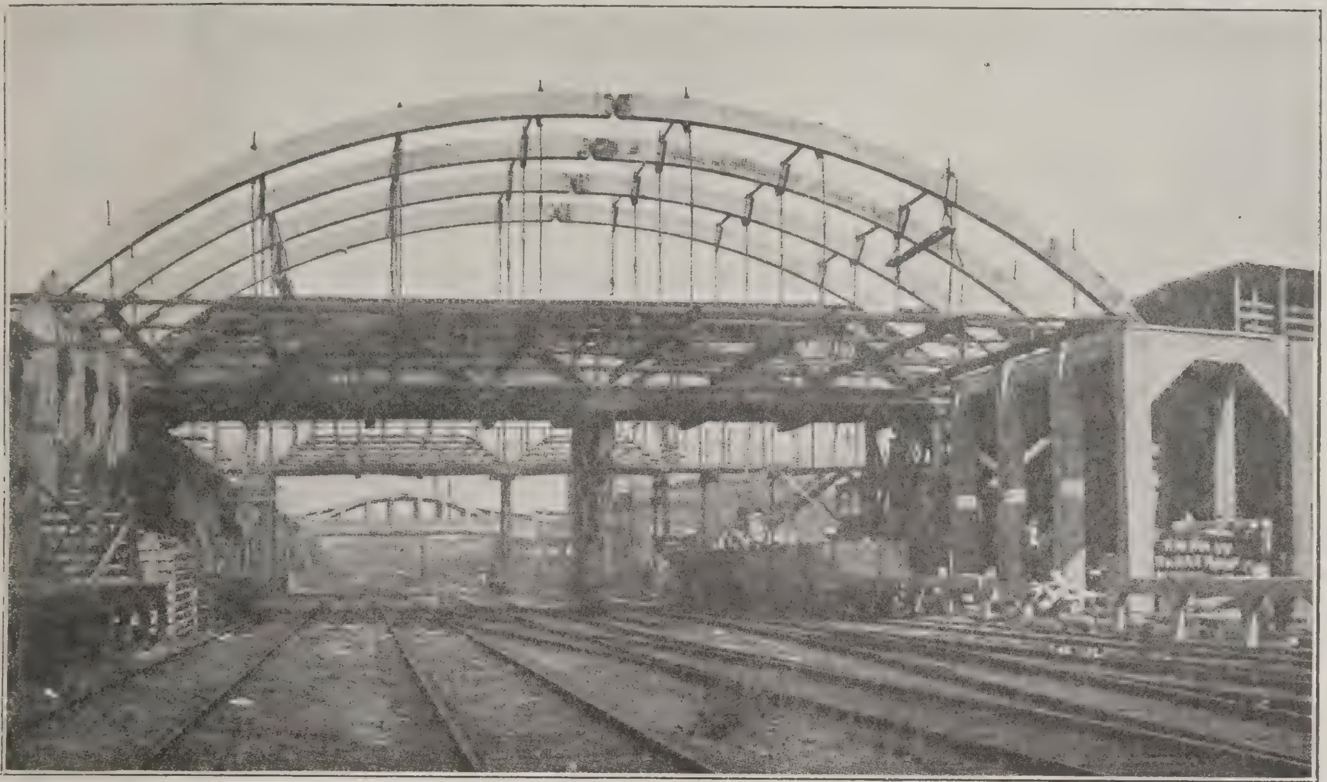
(To be concluded.)

Kirsch (Proceedings of the International Association for Testing Materials) reports that repeated loads of 1.2 kilos per square centimetre do not produce any alteration in the adhesion between iron and concrete, whether the latter be made of Portland cement or with slag cement. After fifty loads the adhesion of bright iron in Portland cement concrete (three months old) was 13.58 kilos. per square centimetre, as compared with an initial adhesion of 13.27 kilos., whilst with rusty iron the original adhesion of 8.78 kilos receded to 7.01 kilos. The loss of adhesion in the case of rusty iron was greater with slag cement, falling from 6.50 kilos. to 5.33 kilos. Expressed in percentages of the original adhesion, the diminution amounted to 4.5 with Portland cement and 15 with slag cement after one month, and to 27 and 27.7 respectively after three months.



THREE-HINGED CONCRETE TRUSSES: AN INTERESTING NOVELTY.

These trusses have been used at the yards of the Union Stock-yards and Transit Company of Chicago. The arch ribs were cast in two separate segments, and provided with hinges to form a three-hinged arch when placed in position.

THREE-HINGED CONCRETE TRUSSES.

During the past two years extensive reinforced concrete constructions have been carried on at the yards of the Union Stock Yards and Transit Company, of Chicago, Ill. Of the many structures, such as viaducts, bridges, platforms, and cattle pens, so far completed, the most interesting and unique in design and method of construction are a number of three-hinged arch trusses, which being so different from the ordinary reinforced concrete arches, a short description of them is of unusual intrest.

Three distinct designs, consisting of an ordinary Pratt truss of structural steel, a structural concrete girder, and a three-hinged segmental arch truss of reinforced concrete, were prepared by Mr. H. Milton Boyajohn, under the direction of Mr. Pierre Holmberg, consulting engineer, of Chicago. On account of the character of the work, and the conditions surrounding it, as well as the economy of cost, the latter design was adopted.

These arch trusses replace the old timber viaducts carrying a large traffic of cattle, sheep and hogs, which it was required to maintain without obstruction during the execution of the reconstruction. The old timber structures were not safe to support additional loads, and there was not room available for erection operations of any type of monolithic structure, and, in order to save a large expense which would have been involved by the reconstruction of new and removal of old timber viaducts, to shift the runs from their present position considerable pains were taken to develop in advance the details of a simple and economic method of executing the work rapidly and safely. All these requirements have been accomplished by an unusual system representing some interesting and ingenious features.

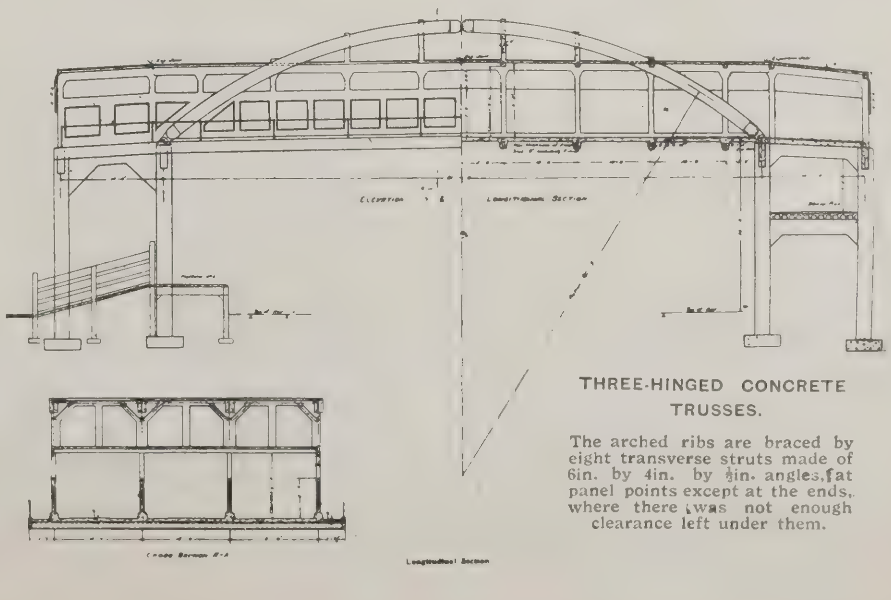
The prerequisite object of this design was to erect rapidly a self-supporting structure that could be utilised during the course of construction to take care of the movement of live stock, which had to be maintained continuously for an average of eight hours daily.

The arch ribs were cast in two separate segments, and provided with hinges to form a three-hinged arch when placed in position. The other members of the structure, consisting of lower chord tension bars, vertical suspension rods, transverse lateral bracings, and channel beams, were all of structural steel embedded in concrete afterwards. Although this is not a case where such a system was originally practised, it represents a distinct departure from the ordinary system of monolithic construction, with costly methods of centering, falsework, and forms, as well as the use of excessive concrete in building heavy abutments, into a recent and economic system of so-called piece construction with pre-made separate members, developed at the yards of the Union Stock Yards and Transit Company, and applied to various types of structures. Most of these viaducts were designed to span five parallel railroad tracks and two receiving platforms, 10ft. wide, one on each side of the tracks, making a clear span of 81ft., from centre to centre of bearings. Viaduct No. 1, which is already completed, consists of four segmental arch ribs of 15ft. 6in. rise, spaced 12ft. apart. Each rib is divided into two semi-ribs, and provided with cast-steel hinges, both at the crown point and the spandrels, making a three-hinged arch, as shown in the accompanying illustrations.

These ribs have a uniform cross section, 20 by 15ins. and are reinforced with four 2½ by 2½ by ¼in. angles, latticed together, forming a regular skeleton. The truss was designed to carry a live load of 100lb. per square foot, besides the dead load. The line of pressure of the equilibrium polygon resultant from the above loads follows closely the neutral axis, so that the rib is practically all in compression, the maximum unit stress in the concrete not exceeding 750 pounds per square inch.

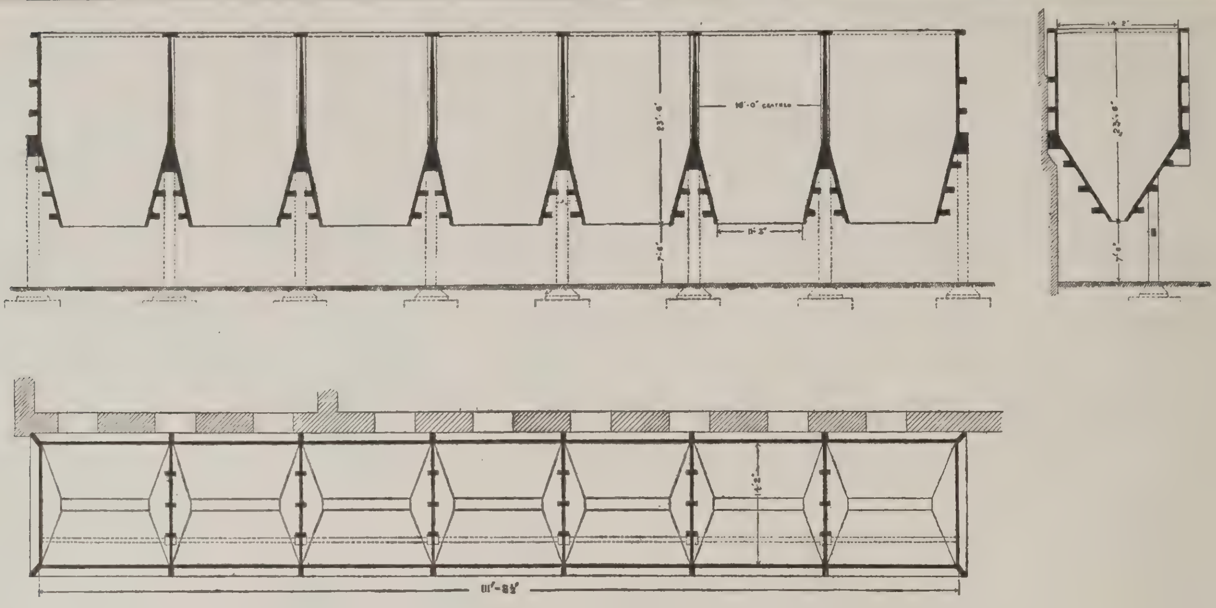
The concrete is made of 1:2:4 mixture, consisting of one part of Portland cement to two parts of torpedo sand to four parts of washed gravel, not exceeding ¾in. in size. Tests on similar mixture of concrete cast in our factory showed an average strength of 2,800lbs. per square in., on specimens from 60 to 90 days old.

Each rib is divided into nine panel points, symmetrical about the centre crown hinge, and varying from 11ft. at the centre to 5ft.



THREE-HINGED CONCRETE TRUSSES.

The arched ribs are braced by eight transverse struts made of 6in. by 4in. by ⅜in. angles, at panel points except at the ends, where there was not enough clearance left under them.



REINFORCED CONCRETE WASHERY BUNKERS.

These washery bunkers were executed for the Powell Duffryn Steam Colliery, South Wales, by Messrs. Heenan and Froude, of Manchester, on the Coignet system.

at the haunches. At the panel points, 2in. holes for the vertical suspension rods (1⅞in. diameter) are provided by placing 2in. gas pipes through the centre line of the rib. The upper end of the suspension rods is provided with upset thread, two nuts and 6 by 6 by 1in. washer which bears directly on the arch rib, and the lower end with an eye to engage the transverse floor girders consisting of two 10in., 15-pound channels. The 6in. floor slab reinforced longitudinally by No. 38 wire, and supplemented with ¾in. rods, is supported by these channel girders.

The bottom chords consisting of four 3 by 1in. eyebars with adjustable turnbuckles, were designed to take the horizontal component of the end truss of the arch. The concrete in which they are embedded afterwards is intended only as a stiffener and protection for the steel.

The arch ribs are braced by light transverse portal-like struts made of 6 by 4 by ½in. angles, at panel points except at the ends, where there was not enough clearance left under them.

All piers, which were constructed in place, consist of two rows of columns, 24ins. sq., having their centre lines 14ft. apart and connected at the tops by 12 by 24in. logitudinal and transverse beams with heavy brackets. Each row of columns rests on a sill, 12ins. deep, 5ft. wide, and 42ft. long, laid on firm clay foundation and reinforced heavily with ¾in. round rods.

The cost of form work, etc., was exceedingly small. Two men could easily arrange the forms, place the reinforcements and concrete two ribs in one day.

After allowing thirty days for the ribs to set, they were picked up by a derrick, loaded on cars, and switched out to the bridge site where they were placed in position by a derrick. Before setting these ribs in place, the lower cord eye-bars were placed from end to end pin. Finally the transverse portal struts, vertical rods and channel girder were placed in position. The old timber viaducts were then taken down and a temporary floor built in one of the runs to take care of the cattle movement, while the other two runs were being constructed. The forms for the rest of the structure were then rapidly constructed, all the reinforcement put in place, and concrete poured, care being taken to keep a continuous run of concrete until a point was reached where a good joint could be made. Provision was made for the rest of the viaducts to construct the floor in separate pre-made floor joists, cast in the factory.

The erection of the separate members of the structure was accomplished in six days, with a gang of ten labourers and a foreman, and concreting the floor, roof, girders, etc., was done in less than thirty days.

The structure has proved very satisfactory in all respects. Level readings taken at the centre of the lower cord as well as at the top of the crown with full live load in three runs, indicated ⅛in. maximum vibratory deflection.

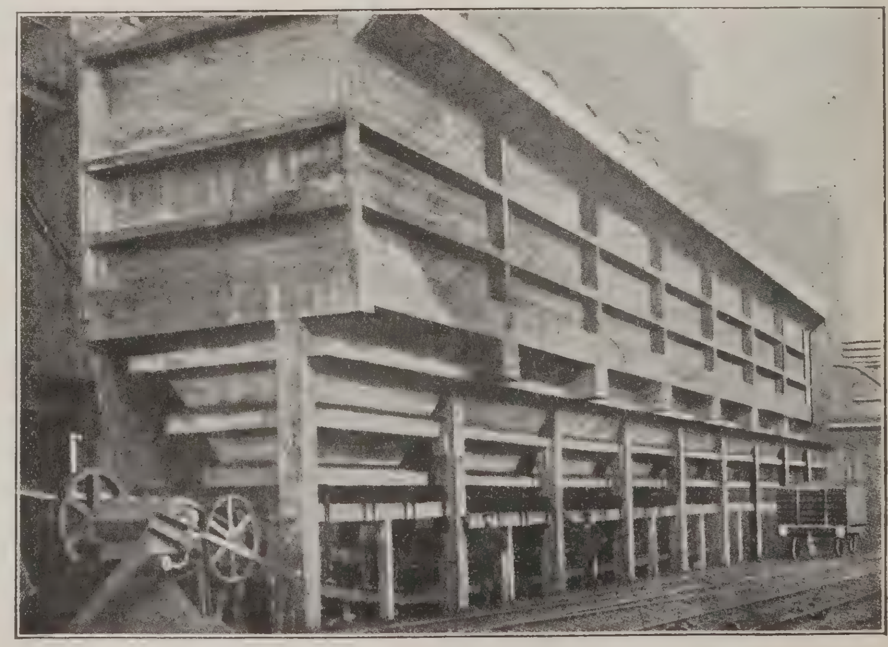
REINFORCED CONCRETE IN MINING WORK.

A small pamphlet has been published by Messrs. Edmond Coignet, Ltd., of 20, Victoria Street, which deals with the subject of reinforced concrete as it has been applied to mining and similar industries by the firm in question.

Reinforced concrete is finding its application in connection with mines in many ways, not only in respect of the construction of such structures as bunkers, water tanks, and foundations of engine houses, but for the construction of parts of the mining plant and outfit, as, for instance, in pit-heads, and pit-props, and also for the lining of shafts. From this small pamphlet we reproduce the accompanying illustration of washery bunkers, which were executed for the Powell Duffryn Colliery in South Wales by Messrs. Heenan and Froude, Ltd., of Manchester, licensed contractors on the Coignet system. In this particular work there were seven bunkers having a total length of 112ft. Each bunker measures 16ft. by 14ft. 2ins., and has a height of 23ft. 6ins. They contain water and coal dust, and it is possible to entirely fill any particular bunker in a few minutes. The cubic capacity of the seven bunkers amounts to about 27,000 cub. ft.

Our Plate.

"Great Roke," Witley, Surrey, is an admirable example of the excellent work of Messrs. Buckland and Haywood-Farmer. Additional charm is lent by the oriel windows. The rooms, it will be seen, are arranged in a most convenient order, several of the many difficulties invariably encountered in domestic work in which the area is at all extensive being very neatly solved.



REINFORCED CONCRETE WASHERY BUNKERS.

An interesting application of reinforced concrete. Each bunker measures 16ft. by 14ft. 2ins., with a height of 23ft. 6ins.

Trade and Craft.

Concrete Blocks and a Mixer.

The concrete block industry is growing in in this country, thanks to the "push" of enterprising manufacturers of machines for their manufacture. The concrete block, when properly made, is an economical building material, and also possesses good appearance and durability. Its cheapness, indeed, is not its sole merit, for it is lasting, and dwellings erected with such blocks are dry and sanitary, and warm in winter and cold in summer. Many builders and estate owners are now adding concrete blockmaking machines to their plant, and are finding them as serviceable in ordinary building operations in this country as they have been proved abroad, though, perhaps, the advantages they offer are not so great here as in an undeveloped country where other materials are expensive and difficult to obtain. There are various types of machines on the market. The "Winget" machine is one of the best. It comprises some novel features. Whereas most machines require the core forming the hollows in the block to be withdrawn by the operation of a lever, and the mould to be unclamped and turned down by hand, for the removal of the block, and the reversal of these operations to get the machine ready for making another block, the great feature of the "Winget" machine is that all is done by one operation, namely, pulling a lever. Pulled down, the block is released, put back, the mould is again ready for filling. This is time and labour economised and simplicity of action secured. Often several machines are needed to make the several kinds of blocks required, but not so with the "Winget" machine. It makes all sizes of blocks and specials from 32ins. by 16ins. by 9ins. downward. It makes hollow or solid blocks, and with division places can make 4 separate blocks at a time. It can be arranged to make specially moulded blocks by the insertion of different plates or cores. The machine consists of a mould box with hinged sides and ends carried in the frame hung in trunnions, with core blocks set inside. When the lever is pulled down, the bottom of the mould box, which is formed by a loose pallet inserted for each block, is lifted up, and at the same time the sides of the box fall outwards, leaving the finished block on the pallet ready to be carried off. The cores are carried on a fixed bed plate under the pallet forming the bottom of the mould box. Normally, in the side-face position, the machine can be used in the face-down position by swinging over in the trunnions the frame carrying the mould box into a horizontal position by means of the same lever, first releasing a stop. A minimum output of 200 blocks per day is guaranteed, but an average of 300 blocks have been turned out over a period of 3 months. The (U.K.) Winget Concrete Machine Co., Ltd., of Star Buildings, Northumberland Street, Newcastle-on-Tyne, also supply a concrete mixer known as the "Express." This consists of a sort of mortar mill pan with plough blades on axis within to mix the material. It is a batch mixer, and contains few working parts (and these are easily got at) to require renewal or repair. The material can be seen as it is being mixed, and this is an advantage as regards securing uniformity of output and thorough mixing of concrete.

Lifts at the New Strand Palace Hotel.

This new hotel is being fitted with a very complete system of elevator service by Messrs. R. Waygood and Co., Ltd,. London. There are two main passenger lifts, each capable of carrying a load of 10 cwts., or 7 persons, at a speed of 300ft. per minute. One of these lifts is worked by hydraulic power from the high pressure main of the London Hydraulic Power Co., and the other one by electric power, the latter being arranged with winding gear and special electrical control with car switch in the cage. Special electrical indicators are also fitted on each lift, showing the position of each lift at every floor by means of ornamental fitting with electric light. The cages are handsomely finished and decorated, and are provided with special safety apparatus to prevent the descent of cage in case of suspension ropes failing, also with safety appliances to guard against over travel in either direction. There are two goods lifts travelling up through the building, one operated by hydraulic power, and capable of carrying loads of 15 and 20 cwts. and one direct acting platform lift, from basement to ground floor. There is a very complete installation of electric service lifts—15 in number—serving the various floors. There are also three small hand-power lifts, for carrying wine and papers respectively.

Federation News.

South Western Federation: Half-yearly Meeting.

The half-yearly meeting of the South Western Federation was held at the Guildhall, Small Street, Bristol, on August 6th.

The half-yearly report was read by the secretary and adopted.

The treasurer presented his half-yearly statement and report, which was regarded as being very satisfactory, and was adopted.

A discussion took place as to the recommendation contained in the report with regard to apprentices, and the secretary was instructed to write to the local association and impress upon them the advantages to be derived by the employers in increasing their number of apprentices.

The question of sending in bills of quantities with tenders was discussed, and it was pointed out that the practice in this Federation, except in regard to the case of engineers, was that the bills of quantities were not opened unless the tender was accepted.

Mr. George Hayward (Bath) brought forward the question of the amount for which an estimate should be given without quantities being supplied. He pointed out that it varied in different towns in the Federation, and might lead to some friction.

It was arranged that a conference on the matter should take place between Bristol and Bath Associations.—W. F. Long, secretary, Northumberland Buildings, Queen Square, Bath.

BARROW-IN-FURNESS ASSOCIATION.

Secretary: J. Baker.

The monthly meeting of the Association was held on Tuesday, August 31st, and was well attended.

The secretary reported as to correspondence *re* the appointment of a teacher for the proposed plumbers' class in connection with the Borough Technical School, and approval was given to the appointment of Mr. Nichols, bronze medallist. It was also resolved to encourage the apprentices to attend the classes by additions to their wages in the event of their winning 1st and 2nd class prizes, and if attendance had been satisfactory.

In order to stimulate attendance of members at the monthly meeting of the association, it was resolved to inflict a 1s. fine on all who do not attend one meeting in a quarter.

Approval was given to the draft of a letter to be sent to the Town Clerk respecting the arbitration clause inserted in all the corporation contracts, such clause setting for the borough engineer as sole arbitrator, the judge in a recent case having given judgment against it.

MIDDLESBROUGH ASSOCIATION.

Secretary: Walter Rigby.

The monthly general meeting of the Middlesbrough Association was held in the Corporation Hotel, on Wednesday, September 1st.

The president (Mr. W. Masters) presided over a fair attendance of members.

It was reported that the conference between the Executive Committee representing the Teesside Federation of Master Builders and the representatives of the employees connected with the different branches of the building trade in this district, *re* uniformity of working hours, had come to nought owing to a condition put forward by the employees that one of the branches concerned should receive increased wages as an equivalent for a reduction of hours worked in order to secure uniformity. The Federation found it impossible to agree to this, and the conference was immediately adjourned.

At a previous meeting, Mr. P. Bray drew attention to a new order issued by the borough surveyor of this town, in reference to the height of a ceiling in a back bedroom, carried over a scullery. He further explained that up to a short time ago, Middlesbrough builders had been in the habit of putting on the wallplate at 7ft., ceiling up the spar, fixing the ceiling joists across at 9ft., and calling it a room "partly in the roof," as per by-law. This had been the custom since the by-laws came into force in 1901. Recently a new surveyor had come to the town, and a change is to be made. He advises the Plans Committee that the above is not a room "partly in the roof," with the result that the Corporation now decline to pass any plans unless the back rooms are shown to be 9ft. at the eaves.

This change was felt by the meeting to be a very serious matter, especially to speculative builders. But before taking the matter up with the Corporation the secretary was instructed to write other towns for information as to the working of the by-law in their districts.

The report of our representative (Mr. W. Masters) to the National meeting at Portsmouth was received and adopted. Mr. Masters was heartily thanked for a detailed and very interesting report of those meetings.

The president spoke strongly of the advisability of each member of this association becoming a subscriber to the "Builders' Journal," and advocated the policy of the Sunderland and the Oldham Association in this matter, viz., part subscription paid by member and part by the association. The secretary was instructed to place the matter upon the agenda of a later meeting, as it was felt that an expression of opinion upon this question from the whole of the members was desirable.

Correspondence from the Northern Counties Federation, *re* "Fair Wages Clauses in Contracts," and "Comparative Statement of Hours and Wages," was read.

It was decided that the smoker postponed in April last till later in the year be held at the close of the next monthly meeting in October in the Corporation Hotel, and a committee was appointed to make the arrangements.

WARRINGTON AND DISTRICT ASSOCIATION.

Secretary: Bertram B. Moss.

Several months ago, the Warrington Association served notices upon the operative bricklayers and operative joiners of Warrington for a decrease in wages of ½d. (halfpenny) per hour, and slight alteration to the boundary and other rules. A counter-notice was received for an advance of ¼d. per hour (one farthing) and slight alteration to the rules from both trades. After lengthy negotiations, the following settlement has been arrived at:—Wages to remain as at present, viz., 9¼d. (ninepence farthing) per hour with regard to both trades; in the case of the bricklayers, a slight reduction in the winter hours, and in the case of the joiners a slight reduction in both summer and winter hours; also other minor alterations to the rules.

The Lancashire, Cheshire, and North Wales Federation have forwarded their "Half-yearly Report, List of Members, and Year Book," compiled by Mr. Robert Hall, Cromwell Buildings, Blackfriars, Manchester. We hope to deal with it next week.

COMPLETE LIST OF CONTRACTS OPEN.

In this list are included, as a rule, only those contracts for which tenders are returnable about **five days** after the date of this issue.

Unless expressly stated to the contrary, all deposits required for bills of quantities, etc., are returned ontreceipt of *bona-fide* tenders.

The words "Fair Wages Clause" inserted in certain paragraphs signify that persons tendering must conform to a fair wages clause in the Contract, which requires them to pay the rates of wages current in the district.

BUILDING.

Sept. 17—27. **FERMOY (Ireland).**—Erection of 12 "A" married soldiers' quarters, Fermoy, Ireland. Plans, specification, and conditions of contract may be inspected at the office of the Director of Barrack Construction, 80, Pall Mall, London, S.W., or at the Barrack Construction Office, Fermoy, Ireland, on Monday, Tuesday, and Wednesday, September 13th, 14th, and 15th, 1909. Those desiring to tender and to receive a copy of the bills of quantities must apply to the Director of Barrack Construction not later than Friday, September 17th, 1909. The application must be accompanied by a deposit of 10s., which will be returned if a bona-fide tender is received from the applicant. Cheques or orders to be made payable to the Assistant Financial Secretary and crossed "Bank of England for Credit to Army Funds." Tenders on the form supplied with the bills of quantities, must be delivered in sealed envelopes, marked "Tender for 12 'A' Married Quarters, Fermoy," not later than 12 noon on Monday, 27th September, 1909, addressed to the Director of Army Contracts, War Office, Whitehall, London, S.W. The bills of quantities should accompany tender in a separate sealed envelope, similarly addressed and marked "Bills of Quantities, ———," with the contractor's name and address thereon.—H. de la Bere, Director of Army Contracts, War Office, Whitehall, London, S.W.

Sept. 18. **SUNDERLAND.**—Erection of proposed new stables and carpet-beating shed, etc., High Barnes Terrace, for the Grange Laundry Co. Plans may be seen, and quantities obtained at the office of the Architects, 20, Fawcett Street. Tenders, sealed and endorsed, to be delivered to Wm. and T. R. Milburn, FF.R.I.B.A.

Sept. 18. **AYLESBURY.**—Effecting sundry internal alterations at the Judges' Lodgings, Aylesbury, for providing offices upon the upper floor, for the Bucks County Council. Plans and specification may be seen, and form of tender obtained, at the office of R. J. Thomas, county surveyor, County Hall, Aylesbury, where sealed tenders are to be delivered.

Sept. 18. **GLAMORGAN.**—Erection of a County Hall in the Cathays Park, Cardiff, upon foundations which have already been laid, for the Glamorgan County Council. Plan and specification and form of contract may be seen, and copies of the bills of quantities obtained (on payment of a deposit of two guineas, which will be returned after receipt of a bona-fide tender, according with the particulars and conditions laid down), at the office of the Architects, Messrs. Harris and Moodie, 8, New Square, Lincoln's Inn, London, W.C. Tenders made out on the forms supplied and securely sealed in the envelopes supplied with the quantities are to be delivered here on or before Saturday, 18th September.—T. Mansel Franklen, Clerk of the County Council, Glamorgan County Council Offices, Westgate Street, Cardiff.

Sept 20. **NEWPORT (Mon.).**—Necessary work in connection with the pulling down of the existing bridge at Pontllanfraith, and the erection of a steel structure, for the C.C. Plans and specifications may be seen at the office of William Tanner, F.S.I., County Surveyor, and a copy of the quantities obtained on deposit of £1 1s. Tenders to be sent to the County Surveyor.

Sept. 20. **CAMBRIDGE.**—Erection of additions to the sewage pumping station, Riverside, Cambridge, according to plans, etc., prepared by the Borough Surveyor, for the Corporation. Plans and specification may be seen at the Office of the Borough Surveyor, Guildhall, where other particulars and form of tender can be obtained. Tenders to be sent to J. E. L. Whitehead, Town Clerk, Guildhall.

Sept. 20. **HAVERFORDWEST.**—Erection of 14 brick-built houses at Prendergast, under the Provisions of the Housing of the Working Classes Acts. Plans may be inspected and copies of the specifications obtained at the Borough Surveyor's Office, Council Chambers, Haverfordwest. Tenders sealed and endorsed "Tender for Houses," must be delivered to the undersigned not later than noon on September 20th.—R. T. P. Williams, Town Clerk.

Sept. 20. **LAURENCEKIRK.**—Works to be executed in the construction of new station buildings at Laurencekirk, for the Caledonian Railway Co. Drawings may be seen at the office of the Company's Engineer, Buchanan Street Station, Glasgow, where copies of the specification and schedule may be obtained on deposit of £2 2s. Tenders to be lodged with J. Blackburn, Secretary, Caledonian Railway Company's Offices, 302, Buchanan Street, Glasgow.

Sept. 20. **SMETHWICK.**—Erection of various buildings at the depot in Rolfe Street, Smethwick, for the Corporation. Plans and specifications can be seen, and bill of quantities obtained, at the office of the undersigned. All applications for quantities must be accompanied by cheque deposit of £3 3s. Tenders to be sent in under seal, addressed to the Chairman of the Public Works Committee, and endorsed "Tender for Depot," and delivered to C. J. Fox Allin, Borough Surveyor, Council House, Smethwick. Fair wages clause.

Sept. 20. **WEARDALE.**—Erection of three stone bridges on the road from Eastgate to Rookhope, for the R.D.C. Plans may be seen and specifications and forms of tender and other information may be obtained on application to G. W. Egglestone, the Highway Surveyor, at his office at the Board Room of the Guardians in Stanhope. Specifications and forms of tender on deposit of £1. The bridges will be let together or separately as the District Council may think fit. Tenders should be sent to F. H. Thompson, Clerk to the District Council, Stanhope.
